

Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

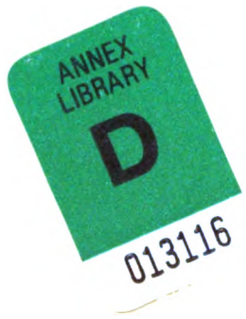
+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google



El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

BOUGHT WITH THE INCOME
FROM THE
SAGE ENDOWMENT FUND
THE GIFT OF
Henry W. Sage
1891

A226532 11/9/05

9963

The date shows when this volume was taken.
To renew this book copy the call No. and give to the librarian.

HOME USE RULES.

All Books subject to Recall.

Books not used for instruction or research are returnable within 4 weeks.

Volumes of periodicals and of pamphlets are held in the library as much as possible. For special purposes they are given out for a limited time.

Borrowers should not use their library privileges for the benefit of other persons.

Books not needed during recess periods should be returned to the library, or arrangements made for their return during borrower's absence, if wanted.

Books needed by more than one person are held on the reserve list.

Books of special value and gift books, when the giver wishes it, are not allowed to circulate.

Readers are asked to report all cases of books marked or mutilated.

Do not deface books by marks and writing.

EDITORIAL NOTES

Artificial Loads for Testing Generators, 423

Berry's Distribution System, 185
Bohle's Paper on Illumination, 876
Brake Gear Design, 4
Brighton Sub-Station Nuisance, 149
Bruce Peebles & Co., Liquidation of, 257

Cable-Laying, Direct in Ground *versus* "Solid" System of, 612
Cables, Correspondence Relating to Cost of C.M.A., 801
City of London, Street Lighting in the, 841

Docks, Electric Power in, 297
Dublin and Central Ireland Electric Power Bill, 541
Dysprosium, Magnetic Oxide of, 802

Electrical Power, Cost of, for Industrial Purposes, 69, 149
Electricity Supply in Germany, Government Monopoly of, 35
Electrolytic Corrosion, 541

Factories and Workshops, Electricity in, 111
Flame Arc Lamp, A New Enclosed, 298
Franco-British Exhibition, Co-operative Exhibit at the, 579, 683
Fuse Phenomena [SCHWARTZ], 380

Garrard's Paper on A.C. Switchgear Relays, 761
Gee's Paper on Electrolytic Corrosion, 541
German Government Electricity Monopoly, 35
Glasgow Tramway Accident, Report on the, 951
Goldschmidt's Paper on Standard Performances of Electrical Machines, 149
Greenock Refuse Destructor Plant, 257

Handcock & Dykes' Paper on Metal Filament Lamps and Lighting Industry, 579
High-Speed Electrical Machinery, 541
Hirst's Paper on Metal Filament Lamps, 761, 801
Home Office Regulations, The New, 359, 379, 423, 461, 501

Institution of Electrical Engineers (Council, 1908-9), 647; (Annual Report), 841; (Proposed Purchase of Building), 951

Kelvin Memorial, 298
Kennelly's Graphic Method for Finding the Mean Spherical Candle-power, 876

London, Brighton & South Coast Railway Electrification, 914
London County Council Tramway Accounts, 462
London Electric Power Bills, 185, 719, 914, 951

Manchester Electrical Exhibition, 423
Manchester 6,000-kw. Turbo-Alternator, 719
Metal Filament Lamps, 223
Metal-Filament Lamps and the Electric Lighting Industry, 579, 647
Metropolitan Railway Accident, The, 70, 185
Midland Railway, Electric Traction on the, 875, 913
Morcom & Morris: Paper on "Artificial Loads for Testing Generators," 423
Municipal Electrical Association, The Annual Meeting of the, 875, 950

National Physical Laboratory, The Grievance Against the, 339

Osram Lamp, Hirst's Paper on the, 801

Paddington Borough Street Lighting, 611
Patent Office Procedure, The New, 3
Peck's Paper on Protective Devices, 224
Pringle Emergency Tramway Brake, The, 647
Private Telephone Lines, 841

Railway Goods Warehouses, Electric Power in, 297
Refuse Destructor Plant at Greenock, 257
Rolling Mills, Electric Driving of, 398

Schwartz's Paper on Fuse Phenomena, 380
Scottish National Exhibition, 683
Single-Phase Distribution, A New System of, 35
Single-Phase Traction, 35
Snell's Paper on Cost of Electrical Power, 69, 149
Snowstorms and the Telegraph and Telephone Systems, 69
Stevenson's Paper on Polyphase Induction Motors for Industrial Purposes, 611
Stoney & Law's Paper on High-Speed Electrical Machinery, 541
Street Lighting with Metal-Filament Lamps, 683
Street Lighting in the City of London, 841

Telegraph and Telephone Cables, 501
Telegraph and Telephone System, Effect of Snowstorm on, 69
Telephone Lines, Private, 841
Tramway Statistics, 223

Iron Plates, Formation of, 443
Iron, Rusting of, 325, 787, 975

Lead, Chrome, 57
Lead Sulphide, Electrolysis of, 101
Lead Peroxide Deposit on Carbon, 487
Lead, White, 57

Metal Filaments, 525
Metals, Production of Reguline, in Vacuum Arc, 209
Molybdenum, 525
Monox, 563

Nickel from Silicate Ores, 634
Nickel Plating, 101
Nitrates from Atmosphere, 57
Nitrogen, Oxidation of, 669

Oxidation of Atmospheric Nitrogen, 669
Oxygen by Electrolysis of Water, 487
Ozone, Technical Uses of, 746
Perchlorates, 525
Perborates, 635
Percarbonates, 635
Photographs by Electric Waves, 363
Planimetric Analysis of Alloys, 669
Plating Baths, 101
Platinum, Electrolytic Oxidation of, 563
Porcelain, Electrical Conduction of, on Heating, 487
Primary Batteries, 441

Quartz, Furnace for Refining, 899

Rare Metals, Electrometallurgy of, 563
Resistances, High, Measurement of, 937
Röchling-Rodenhauser Furnace, 172
Rubies, Artificial, 635
Rusting of Iron, 325

Silver Peroxide, 669
Silver Plating, 101
Silver, Electrolytic Refining of, 409
Société de Cuivre, 139
Société Française des Products Azotes, 172
Sodium, 139
Spanish Electrochemical Works, 703
Steel in Electric Furnace, 209
Steel Works, Electric, 937

Tanning Hides by Electrolysis, 669
Thermit Process, Modification of, 487
Tin Ores, Electric Smelting of, 703
Tungsten, 525
Turpentine, Distillation of, 822

Viscosity and Conductivity, 25

Water, Electrolysis of, 363
Water, Purification of, by Ozone, 746
Welding of Aluminium, 443

Zinc, Electric Smelting of, 57, 443

ELECTRICAL SCIENCE

Subject Index

Actinium, Active Deposit from, 900
Alkali Metals, New Spectral Lines, 173; Radioactivity of, 787
Alternating Currents, Small, 821; and Permeability, 900, 918
Alternators, Parallel Working of, 919
Ampere Balance and Unit Current, 821
Antenna of Wireless Telegraphy, Theory of, 488
Arc, Iron, 919; Oscillatory, 748; Spectrum of Singing, 564
Atmospheric Ionisation, 101, 821

Cables, Theory of Grading, 748
Cathode Rays, Duration of Emission of, 526; Magnetic Field of, 210; Phosphorescence due to, 326
Clark Cells, Preparation of, 58; E.M.F. of, 821
Colloids, Electric Transport in, 670
Contact E.M.F. between Mercury and Electrolytes, 364

Death, X-ray Test for, 58, 788, 919
Demagnetisation by Reversals, 245
Dielectric Constant, and Dissolving Power, 364; and Rotatory Dispersion, 173
Discharge, from Metallic Oxides, 326; from Pointed Conductors, 444; Through Gases, 410, 444, 487, 525, 564, 598
Dispersion and the Electron Theory, 24
Double Refraction in Magnetic Fields, 24
Dysprosium, Magnetic Properties of, 788, 802,

Electric Oscillations, see Oscillations
Electric Furnace, 284
Electric Lines of Force, 636
Electrodynamics and Mechanics, 976
Electrolysis, of Hydrochloric Acid, 748; in Indigo Reduction, 101
Electrolytic Detector, 410, 488; Interruptors, 526
Electrolytic Iron, Magnetic Properties of, 525
Electromagnetic Induction Laws, 636
Electrometer Binant, 976
Electromotive Force, of Clark Cell, 821; of Prescribed Form, 748
Electron Theory, of Magnetism, 173; of Mass, 245; of Matter, 598; of Optical Dispersion, 24; Relation of Mass to Energy, 173; Relation to Gravitation, 748
Electrons from Metallic Oxides, 326
Energy, and Mass of Electrons, 173; Theory of, 24
Ether, Sir Oliver Lodge on the, 325; Attack on the, 326; and Gravitation, 748

Friction and Electric Current, 24
Furnace, New Electric, 284

Gas Engine Temperatures, 100
Gas from Electrodes of Vacuum Tubes, 58
Graded Cables, Theory of, 748
Gravitation, Theory of, 748

Heusler Alloys, 704
Hydrogen in Allotropic Form, 58
Hygroscope, Electric, 669
Hysteresis in Rotating Fields, 245. See also Magnetic Phenomena

Indigo, Reduction by Electrolysis, 101
Inductance Formulæ, for two Parallel Wires, 210; for Solenoids, &c., 326; Various, 284
Inductance in an Iron Cylinder, 918
Insulators, Resistance of, 704
Interruptor, Electrolytic, 526; Mercury, 976
Ionisation, Atmospheric, 821; by Bubbling, 24; of Gases by Sparks, 564; Measurement of, 670
Ionisation of Colloids, 670

Lengths, Measurement of Small, 444
Light, Dispersion in Space of, 410; Mechanical Equivalent of, 564; Measurement of, 788
Lightning, Colour of, 788
Longitude by Wireless Telegraphy, 598, 670

Magnetic Alloys, 704
Magnetic Double Refraction, 24
Magnetic Phenomena, in Dysprosium, 788; in Heusler Alloys, 704; in Iron, 245, 525, 635, 900, 918; in Alternating Fields, 900, 918; in Rotating Fields, 245; under Thermal Treatment, 635
Magnetic Rays, 410
Magnetic Rotation in Sodium Vapour, 284
Magnetism, Electron Theory of, 173; and Specific Heat, 139; Terrestrial, 525
Magneto-elastic Detector, 488
Magneto-mechanical Effect, 564
Mechanics, Electrical Theory of, 976

Nitrogen, atmospheric, and its fixation, 101

Oscillation Detectors, 410, 488
Oscillations, from Dynamo, 173; from Arcs, 748; from High-tension Sparks, 748; Slightly Damped, 210, 704; Harmonics in Spark-produced, 900

Pendulums, Electric Driving of, 821
Permeability, &c., 245, 525, 635, 704, 788, 900, 918
Photo-electric Phenomena, 100, 488, 526, 636, 669
Photometry, Automatic, by Radiomicrometer, 788
Points, Discharge from, 444
Power in Three-phase Circuits, 210
Positive Electrons, Nature of, 598; in Sodium Atom, 284; Spectroscopic Evidence, 210, 284, 636
Positive Rays, Doppler Effect, 138; Nature of, 598; Phosphorescence due to, 326; counted by Spinthariscope, 444

Radioactivity, of Actinium, 900; of Alkali Metals, 787; Atmospheric, 101; Nature of γ-Rays, 636; Heat Developed in Thoria, 821; Scattering of β-Rays, 488
Radium, Colouration of Jewels, 139; and Lithium, 364; Rutherford Lecture on, 210
Rectifiers, Contact, 748; Flames as, 138, 284; Vacuum Tubes as, 976
Resistance, of Insulators, 704; New High, 704
Röntgen Rays, Nature of, 636; Test for Death, 58, 788, 919; Wave Length, 444; Current through Tube, 976
Royal Society Conversazione, 787; Studentship, 976

Selenium: Decay of Light-effect, 100; Pressure-effect, 669; Sensitiveness, 488, 636
Sodium Vapour, Magnetic Rotation in, 284
Spark Discharge, Harmonics in, 900; of Inductorium, 597; Length and Voltage, 564; Resistance of, 245
Specific Heat and Magnetism, 139
Specific Inductive Capacity, and Dissolving Power, 364; and Rotatory Dispersion, 173
Spectrum, of Alkali Metals (new lines), 173; of Singing Arc, 564; Theory of, 245, 326
Standard Cells, 58; E.M.F. of Clark, 821

Telephone, Efficiency, 58; Current for Measurements, 821
Terrestrial Magnetism, 525
Thoria, Radioactive Heat of, 821

Uranium, Scattering of β-Rays, 488

Vacuum Tubes, New Gas in, 58
Voltameter, 787
Voltaic Cell Theory, 563

Wehnelt Interruptors, 526
Weston Cells, 58
Wireless Telegraphy, Directive System of 918

Zeeman Effect, 636

SUMMARY

A section dealing with the artificial lighting of schoolrooms is included in the report of the Education Committee of the London County Council. This has been written by Mr. B. Harman, who has conducted an experimental enquiry as to the best positions of the sources of light, the best methods of distribution, and what improvements can be effected by suitable shades. (Page 4.)

The new Patent Act, passed last session, came into force yesterday, and a revised set of rules of procedure by patentees and others has been issued by the Patent Office. The chief novelties are the new "Patents of Addition," and the procedure for obtaining compulsory licences and revocation of patents in the event of the patent not being adequately worked in the United Kingdom. Another useful provision is that, after a provisional patent has been applied for and before the time for filing the complete specification is due, an inventor may file a supplementary provisional patent for an improvement or modification of his invention, with a view to the two provisional patents being subsequently embodied in one complete specification, for which a single fee only is chargeable. For the sake of completeness we outline the entire course of procedure for the obtaining of patents, and in the case of other matters with regard to them, as well as the rules that apply to the working of the new provisions of the Act. (Page 5.)

Professor J. T. Morris gave a lecture recently at the East London College, in which he outlined the working of the Griffiths-Bedell surface contact system, which is now being laid down for the L.C.C. tramways in the Mile End Road, and gave the results of some experiments on the magnetic action of the form of stud employed. (Page 7.)

A demonstration of a new system of transmission of pictures was given in Paris on Saturday by M. P. Berjonneau. Experiments were carried out over the telegraph line from Paris to Marseilles, and wireless transmission was also accomplished. The system does not involve the use of selenium, but employs a metallic relief made from the original photograph, over which moves a contact point. In the receiver a moving sensitive film is acted on by a ray of light controlled by a shutter actuated electromagnetically by the line currents. (Page 18.)

The electrical equipment of the "West Shore" Railway, between Utica and Syracuse, forms a good example of the latest American continuous-current traction practice. The main points of interest are the arrangement of the under-running third rail and the 60,000-volt transmission line. (Page 9.)

Mr. J. Erskine-Murray read a Paper recently on wireless communication over sea, in which he dealt

Digitized by Google

in a general way with the principles of wireless telegraphy as at present practised, and the relative proportions in which the various systems are in use. (Page 11.)

AN interesting patent, the specification of which was published on December 27th, is by the Westinghouse Metal Filament Lamp Co., Ltd. This covers a method of securing the metallic filaments of electric incandescent lamps, to the leading in conductors, and the principle relied on is the fact that certain metals have the properties of giving out energy when combined with oxygen, and when a metallic oxide is mixed with these metals and the mass is heated, the reaction will continue without further assistance, and the bodies, especially metal ones, if introduced into such a mixture, can be heated to their melting point. (Page 12.)

THE electrical equipment of the Burbacher-Hütte, which is an example of the utilisation of blast-furnace gases in large gas engines for the production of electric power for rolling mill driving, is described in an illustrated article. Continuous current is employed, and the rolling mills are driven by compound-wound motors. (Page 13.)

AN abstract of an illustrated Paper on the design of brake gear for electric railway cars, read before the American Central Electric Railway Association by Mr. FRED. HECKLER, emphasises the importance of adequate attention to this item in the design of trucks, pointing out the commoner defects, and the ways in which they may be avoided. The illustrations show the arrangements on several American trucks, and analyse the merits and demerits of each. (Page 17.)

A DESCRIPTION is given of some of the forms of the Cooper-Hewitt mercury-vapour lamp on the market in this country, together with some notes on the working of the same. (Page 20.)

INVESTIGATIONS by E. P. HYDE and F. E. CADY, at the United States Bureau of Standards, confirm previous conclusions that the method of testing the mean horizontal candle power of incandescent lamps by rotating the lamp is sufficiently accurate for all practical purposes unless the speed of rotation (200 r.p.m.) far exceeds that laid down by the British standards. When, however, the filament touches the glass at the higher speeds, an immediate decrease in candle power takes place. (Page 21.)

REVIEWS of the following books appear in this issue:—"How to Design a Gas Engine," by Horace Allen; "Hints Regarding the Management and Use of X-ray Apparatus," by F. Bruce; "Popular Fallacies," by A. S. E. Ackermann. (Page 22.)

A SUMMARY of heavy traction installations recently completed or in progress in America, forms part of a recent report of a committee of the American Street and Interurban Railway Association. (Page 23.)

A SHORT article deals with the sources of supply of tungsten ores and the methods of preparation of the metal. (Page 23.)

UNDER "Electrical Science," in the British and American Section, is a note on the effect on friction of the passage of an electric current across a surface. In the Papers abstracted in the Continental Section, ERFLE expounds the electron theory of dispersion; BLOCH studies the iodisation of air by bubbling; COTTON and MOUTON describe their discovery of magnetic double-refraction in nitrobenzene and other aromatic compounds; HELM foreshadows the application of statistical methods to all collective forms of energy. (Page 24.)

UNDER "Electro-Chemistry and Electro-Metallurgy" is given an account of some investigations by K. ARNDT on the relation between the viscosity and the electrical conductivity of solutions and fused salts. A method due to R. SCHAAR for obtaining pure gases or mixtures of gases in varying proportions electrolytically is also described, and the relative advantages of continuous and alternating currents for various kinds of electric furnaces are considered. The new works of the British Aluminium Co., at Kinlochleven, started operations on Christmas Day. (Page 25.)

THE applications to the Board of Trade for electric lighting provisional orders during the session of 1908 number 27. In connection with Fleetwood and Oulton Broad, two applications are made for the same area, so that the actual number of orders that may be granted is reduced to 25. We give the complete list. (Page 25.)

AMONG the specifications published this week by the Patent Office is one by the BRITISH THOMSON-HOUSTON Co., relating to signalling on electric railway systems in which the dynamo at the power house is connected in a special manner, and the signals are controlled by rotary motors. The Westinghouse Metal Filament Lamp Co. have a new method of securing the filament to the leading-in wires. This patent is given in full on page 12. A specification by COWPER COLES relates to anodes for electric deposition, in which the anodes are moveable and can be made to approach the cathodes as the anodes are dissolved away. The BRITISH THOMSON-HOUSTON Co. and WOODBRIDGE have a specification for improvements in switches and switch-controlling mechanism for electrical installations. J. C. LINCOLN has a special construction for electric motors, so as to obtain great range of speed, and also to prevent sparking at high speeds, and also adapts the armature to work equally well in either direction of rotation. (Page 26.)

A NEW section of the Accrington tramways has been opened. The Acton Council are holding an electrical exhibition from January 18th to 25th, 1908. The claims of the injured in the Bradford tramway accident have been settled. The Halifax Corporation have entered into a new arrangement with the National Telephone Company, which came into force yesterday. The Board of Trade have approved of the Hammersmith Council supplying the Franco-British Exhibition with electricity, and terms have been arranged between the Council and the exhibition company as regards payment. The Board of Trade have notified the Hanwell District Council, that if it does not take up its lighting order in the next twelve months it will be revoked. The Haslingden Council are electrifying the steam tramway. The Horbury and Wigan electric lighting orders have been revoked by the Board of Trade. (Pages 27-28.)

A REPORT comes from Montreal that a syndicate of British capitalists is prepared to spend £2,000,000 in Canada's electrical development. The London County Council requires 500 tons of steel slot rails and about 190 tons of conductor rails. A loan of £20,000 is being taken up from the London County Council by the Stepney Borough Council for the purpose of its electrical undertaking, and amongst other towns requiring electrical machinery may be mentioned Wimbledon (a 1,000 kw. turbo-alternator, two water-tube boilers and switchboard), and Rotherham (tramway rails, &c.). A fifth order for a 2,500 kw. Curtis turbine generating set has been placed with the British Thomson-Houston Co. by the County of London Electric Supply Co., Ltd., and the Treforest Electrical Consumers Co., Ltd., has ordered a 3,000 kw. turbo-generator running at 1,500 revs. per minute, from the British Westinghouse Electric & Manufacturing Co. A serious position is indicated in the report of the Sunderland District Electric Tramways Co., Ltd., and owing, it is stated, to bad management in the early stages of the undertaking, the only means of avoiding the appointment of a receiver is the issue of £20,000 prior lien debentures. The debenture holders have agreed to this course. Our Stock and Share List shows a tendency to improvement of some of the London electric railway shares. (Pages 28-32.)

ELECTRICAL engineers form a large proportion of the 20,000 to 30,000 applicants for patents in Great Britain during the year, and we have no hesitation, therefore, in giving prominence to the new rules of procedure that were put into force at the Patent Office yesterday to give effect to the Patents Act passed in the last session of Parliament. Although the chief alterations relate to the new facilities for patenting additions and modifications of patents already applied for, and to the provisions entitling interested persons to claim the revocation of patents or the issue of compulsory licences in the event of a patent not being adequately worked in the United Kingdom, the present occasion is a good one for reviewing the whole patent procedure now in force. A glance through the article which we publish this week will at once create the impression that the procedure has been considerably complicated in recent years. Formerly it was sufficient for the inventor to deposit his specification with the necessary forms and fees, and unless the application was obviously frivolous, or the grant of the patent would be inexpedient for reasons of morality or other good causes, he would be able to obtain a patent in the ordinary course. Now, following the example set by some other countries, a search is instituted by the Patent Office to ascertain whether the invention claimed is novel; but this search extends only to previous British patents and not to other methods of "anticipation," so that the grant of a patent only affords a partial reassurance as to the validity of the patent. On the other hand, it may put the patentee to considerable trouble and expense, for if the Patent Office is of opinion that the patent has in any way been anticipated by a previous one, a sentence calling attention to the fact is added at the end of the complete specification when it is published, although the inventor, it is true, is at first given the opportunity of amending his own specification. If, however, he is convinced that his patent would be a sound one as it stands, and is not inclined to go to the trouble of applying for a "hearing" by the Comptroller, with the possible added expense of appealing to the High Court for a reversal of the Comptroller's decision, he has to submit to the patent being ear-marked as we have mentioned, which obviously may suggest to his business competitors how his own patent may be evaded. Cases are by no means rare in which the inventor, who has applied for this hearing before the Comptroller, is successful in having the opinion of the examiner put aside, and obtains a clean patent without the objectionable added clause. The result is that the services of a patent agent, who is experienced in the "tricks and manners" of the Patent Office, has become an absolute necessity in cases which in former days an intelligent inventor was quite able to tackle for himself. In the rules, the possibility of another hitch is apparent between the application and grant of a patent, but in practice it is one which is of infrequent occurrence. After the acceptance of the patent has been published, it is open to anybody whose interests would be affected to inspect the specification and oppose the grant of the patent. It is somewhat surprising that more advantage is not taken of this facility on the part of rival firms whose interests will possibly be affected by the grant of the patent, for opposition at this stage will cost them far less than a subsequent application for revocation or the defence of an action for infringement. Applications for revocation are rare, however, and those who would be tempted to institute them, as a rule prefer to disregard the patent and leave the *onus* on the patentee of bringing an action for infringement against them subsequently. These actions have always been so costly that the comparatively small number that are heard is in no way a proof that patents are not frequently infringed. Coming now to the new features of the Act, the first is the opportunity given to an inventor of adding improvements to his patent during the period of incubation between the deposit of the provisional and the complete specifications. The inventor who is tempted to improve his patent when drafting his complete specification, and so to risk rendering the patent invalid on account of "disconformity" in order to save the cost of taking out a second patent, will do well to profit by this new facility. On the other hand, the true "patent of addition," which may be taken out at any time and whose cost is lessened by the remission of renewal fees, will probably not be so much in request, for it will bear the same date as the original patent of which it is a modification or addition, and will in consequence expire sooner than if the inventor had taken an ordinary new patent for the improvement. Coming now to the two sections of the new Act for which much commercial importance has been prophesied, we will first take the case in which revocation of a patent may be claimed because the patented article is manufactured mainly or exclusively outside the United Kingdom. At any date not less than four years after the date of the patent, revocation may be claimed on this ground, and although the case may be costly, as the patentee has a right to appeal from the Comptroller's decision, the procedure is fairly simple and straightforward. The effect of this part of the Act will be good, as it will encourage the foreign patentee to start manufacture in this country as soon as possible to avoid the danger of losing his British patent. The case of the metallic filament lamp is one in point. It will be incumbent on many firms owning the British patents for these lamps to start manufacture soon; in fact, the tantalum lamp will have to be made in the United Kingdom before the end of this year if the fundamental patents are to remain valid in this country. We may add that the Act is so worded that the case of an "unrecognised" inventor, who has been unable during the first years of the patent to create a demand for his invention, is not prejudiced, for in such a case the invention would not have been worked outside the United Kingdom any more than it is worked inside. The new provisions with regard to applications for compulsory licences have been welcomed, although they are second in importance to the new law with regard to revocation of patents worked exclusively outside the United Kingdom. Probably advantage of the compulsory licence clauses will first be taken in the chemical industries. Considered as a whole, the new Patent Act will undoubtedly prove beneficial to the industries of this country, and the rules which have been drafted for procedure under it are reasonable and should tend to prevent, so far as is possible, mistakes and misinterpretations.

THE illustrated paper on brake-gear design, of which we publish an abstract, shows that the importance of this matter in the operation of electric railways is being realised in the United States, much as the same question in relation to tramcars is having attention here. The design of trucks for electric traction, in both the light and heavy branches, has not yet received adequate attention from the manufacturers, either in respect to power economy, cost of maintenance, or convenient arrangement of the necessary gear, including brakes and motors. The patterns now in use have been adapted from steam railway practice, and whilst satisfactory for comparatively light towed vehicles, they are not right for self-propelled cars, carrying great weight, much of which is not spring supported. The remarkable rapidity of rail and flange wear on the London tube railways, and the excessive tractive resistance of electric motor-cars, compared with steam railway bogie-cars, show the defects on the driving side. The difficulty of arranging brake rigging on the usual patterns of tramway trucks, and the expense of its maintenance and adjustment, are well known, especially to the operating staff on narrow gauge lines. Generally speaking, they are regarded as inevitable, owing to the inertia of truck builders and the expense of obtaining variations from their standard patterns, but a start has been made in two or three directions to effect improvements, and the near future will bring into the markets trucks which have been designed from the teachings of experience. Adequate treatment of brake rigging is one of the most important items, and a study of Mr. Heckler's paper will direct attention to the essentials as they appear to the responsible officer of an important American electric railway.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 2ND.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster, London, when the President, Mr. W. N. Twelvetrees will open a discussion on "Standard Notation for Engineering Formulæ."

Röntgen Society.

8.15 p.m. Ordinary General Meeting at 20 Hanover Square, London. The Standards Committee will present an interim report.

TUESDAY, JANUARY 7TH.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Meeting at the University. Paper to be read :—"Magnetic Oscillations in Alternators," by G. W. Worrall.

WEDNESDAY, JANUARY 8TH.

Association of Engineers-in-Charge.

7.30 p.m. Meeting at St. Bride's Institute, Fleet Street, London. Paper to be read :—"Electrical Measuring Instruments and Some of their Weaknesses," by K. Edgcumbe.

Junior Institution of Engineers.

8 p.m. Meeting at the Society of Arts, John Street, Adelphi, London. Paper to be read :- "Recent Improvements in Electric Conduit Traction Construction," by Fitz Roy Reese (L.C.C.- Tramways Reconstruction Department).

THURSDAY, JANUARY 9TH.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, London. Paper to be read :—"Cost of Electrical Power for Industrial Purposes," by J. F. C. Snell.

FRIDAY, JANUARY 10TH.

Electro Harmonic Society.

8 p.m. Smoking Concert in the King's Hall, Holborn Restaurant.

LIGHTING SCHOOLROOMS

MR. BISHOP HARMAN has recently undertaken, for the London County Council, an inquiry as to the best positions and source of light, and what improvements can be made, in the lighting of schoolrooms. A large number of tests and experiments have been made, and the minimum amount of artificial illumination permissible has been found to be 10 metre-candles. Gas and electricity were the only illuminants used. Most council schools are lighted by gas, burned directly as an illuminant at the jets of fishtail or bats-wing burners, or used as a source of heat to render mantles incandescent. A suitable room was first tested, hung with four point of gas with Bray's No. 4 burner, with a No. 6 regulator. The effect of this gave a steady flame of high illuminating power. The desk lighting was then examined. These burners were then replaced by Welsbach "C" burners and mantles and "Calypso" shades. Although the gas consumed by these burners was no more than the Bray No. 4 burner, the desk illumination was three times greater. The three types of burners examined were the "C," Kern, and Simplex; the last is the latest pattern and the best; it has the advantage of being 2½ inches shorter than the Kern. This burner was found to be the best of the gas method of illumination, when combined with a 90° shade. Electric lighting was found to be the best, handiest, and simplest method of illuminating the rooms, and there was a complete absence of shadow below the lamp, and the possibility of more efficient reflection. Healthiness and freedom from the consumption of air and production of fumes, noiselessness, all make the electric glow lamp the most perfect means now available for school use. Two sorts of opal shades are in use in schools; one subtends 110° in the sides, and has a vertical depth of 3⅛ inches. The other shade has sides subtending at an angle of 80°, with a vertical depth of 5 inches. This shade completely screens the filament from the teacher's eyes, and, in Mr. Harman's opinion, is best for school purposes. He also examined the "tantalum" and "Nernst" lamps, but found the latter was not good for schoolroom purposes. The report continues :—The distribution of the lamps should be as follows. Each classroom should be considered to be divided into two halves—the pupils' half and the teacher's half, and left-hand lighting must be arranged for as far as possible. There must be a clearance of 6 feet 6 inches beneath the pendants, and the lamp must come somewhat to the left side and slightly in front of the pupil, and the space between the lamps from front to back of the room must be smaller than the space from side to side. Refraction and reflection are much to be recommended for school use. The prismatic and holophane globes are the best for this purpose. The "Prismatic" globe has the outer surface of a glass bowl moulded into a series of prisms running round the bowl, and so placed as to throw the light downwards. It is extremely effective, especially when a flattened opal shade closes the mouth of the bowl. Indirect illumination by reflection is a favourite method in Germany, and this is done by the use of powerful electric arc lamps, hung close to the ceilings with metal reflectors below them. The effect is somewhat like daylight of modified brilliance, and is most successfully employed in workshops and show-rooms, but is not a success for desk lighting. The system was employed in the new anatomical laboratories of Cambridge University, but has had to be superseded by direct glow lamp illumination.

The improvement on the unreflected light by the use of shades is great, but the results obtained by increasing the depth of the shade are most striking. The gain is obtained by reflecting the rays that would otherwise be dissipated upon the upper part of the walls of the room, and the teacher's eyes are screened from the dazzling naked light by the depth of the shade, and the general wall illumination does not suffer. The only suggestion as to the type of incandescent electric lamp which is best for use in schools, is that the lamp should be as large as possible, and the filament be twisted in as long a loop as is convenient, and with electricity, the points of light may be more closely distributed than is the case with gas, as there are no noxious fumes given off. With gas the fewest possible number of burners should be used, for the more burners the worse the atmosphere.

Electrical Science. In the paragraph under "Electrical Science," on page 1050 of our last issue, describing the new current balance at the National Physical Laboratory, the name of Prof. Viriamu Jones should have been mentioned amongst those to whom the design of the instrument was due. In the last line of the same paragraph, 14·9928 should have read 14·99928.

NEW PATENT OFFICE PROCEDURE

THE new Patent Act passed last session, a full *résumé* of which was given in our issue for September 19th, came into force yesterday, and the Patent Office has issued a set of rules for its application. Although the rules have only been altered in some respects, for the sake of completeness we outline the whole procedure that is to be followed when patents are applied for or opposed, when compulsory licences are desired, &c.

APPLICATION FOR A PATENT.

An inventor desiring to acquire a patent has to apply on a form issued for the purpose by the Patent Office. He can either apply for "provisional" protection, or he can hand in a "complete specification" of his invention with his application. In the former case the initial fee is £1, and in the latter case £4. If he has filed a provisional specification in the first instance, he must within six months file a complete specification with an additional fee of £3, so that it costs the same whether he files his complete specification in the first instance or commences with the provisional only. Both the provisional and complete specifications have to be written out in duplicate, and the first sheet of the specification is to be a form provided for the purpose by the Patent Office. Applications may be made by the inventor personally, or through an agent, or may be sent through the post, and the forms must bear a stamp representing the amount of the fee to be paid.

If the Patent Office finds, after examination of the complete specification, that it comprises several distinct inventions, the inventor will be required to amend his application so that it shall include one invention only, but the applicant may apply for separate patents for the other inventions, and if these patents are granted the controller may give these the date of the original application or any later date up to the time they are deposited.

An inventor who has filed a provisional specification, and who has extended or modified his invention before he has left his complete specification, may file a second provisional specification for the addition with a view to the whole being embodied in one complete specification. In this event the patent will bear the date of the first application, except so far as questions of validity and oppositions are concerned. This is one of the additional facilities granted to inventors by the new Act.

At the end of his complete specification the inventor must in all cases state in clear and succinct terms what is the invention claimed, and these claims are to be separate and distinct from the body of the specification.

A month's extension of time is allowed beyond the six months' interval between the filing of the provisional and complete specification, on application on the desired form with payment of a supplementary fee of £2.

In cases where drawings accompany specifications, certain rules are to be observed, and copies of instructions may be had on application at the Patent Office.

EXAMINATION OF PATENT BY THE PATENT OFFICE.

After the complete specification has been deposited an examination is made to ascertain that the invention described in the complete specification is substantially the same as that described in the provisional, and that it has not been anticipated by other British patents published within the previous fifty years. [From a date which will be fixed subsequently by the Board of Trade, this search will also be extended to those specifications which, although already deposited, have not yet been published.] If, after examination, it is considered that there is disconformity between the provisional and complete specification, or if the patent has been wholly or partly anticipated, the inventor will be informed of the facts and will be given the opportunity of renewing his specification within two months of the date of this notice. Should he not be satisfied with the Patent Office decision with regard to the anticipation, he may apply to the Comptroller for "a hearing," and an appointment will be given him with ten days' notice. If the applicant does not apply for a hearing, or does not keep his appointment, or if the Comptroller after the hearing decides against him, the following sentence is added at the end of the complete specification after the claims: "Reference has been directed in pursuance of Section 7, sub-section 4, of the Patents and Designs Act, 1907, to Specification Number .....of....."

The inventor has the right, however, to appeal against this decision to the Law Officer of the Crown, which he must do on a form with a £3 stamp. He must do this within 14 days of the date of the decision, and must address the form to the Chief Clerk, Law Officer's Department, Room 549, Royal Courts of Justice, London. At least seven days' notice will be given of the hearing of the appeal, and no further evidence may be given in addition to that which the inventor gave before the Comptroller, unless special permission is granted. The Law Officer may award costs against the applicant.

In the case of chemical inventions, the Patent Office may require that samples should be deposited, and there are specific directions as to the size of the bottles, the method of labelling, &c.

When the complete specification is accepted, a notice is published in the Official Journal of the Patent Office, and the specification is open to inspection by anyone before it is actually printed and published, on the payment of a fee of 1s.

OPPOSITION TO GRANT OF PATENT.

Any person may, within two months from the date of the above notice in the journal, give notice of opposition to the grant of the patent on certain grounds which are set forth in Section 11 of the Act and published in our previous article above referred to. The opposer must send in his notice on a form prescribed for the purpose, and pay a fee of 10s., and he must give the reasons for his opposition on this form, which is to be accompanied by an unstamped duplicate copy. In certain cases the notice of opposition should be followed in 14 days by a statutory declaration in support of the same (made in the ordinary course before a Justice of the Peace, Commissioner of Oaths, or other qualified official), and the opposer must furnish the applicant for the patent with copies of such declarations. The latter may reply with statutory declarations in support of his case.

When all the evidence has been sent in in this manner, a date is appointed for the hearing, and either party desiring to avail himself of the privilege must notify his intention of attending, on the prescribed form, and pay a fee of £1.

COST OF AN UNOPPOSED PATENT.

If there is no opposition to the grant of the patent, and everything is in order, the patent is "sealed" after acceptance, upon payment of a further fee of £1, together with applications on the proper form.

Assuming that there is no opposition to the grant of the patent, and that there has been no appeal to the Comptroller or to the Law Officer of the Crown, the first cost of a patent, which gives protection for four years, is therefore £5. Before the expiry of the four

Digitized by Google

years, the patent may be renewed from year to year on payment of fees on a rising scale: £5 for the fifth year, £6 for the sixth year, £7 for the seventh year, and so on up to £14 for the fourteenth year. Fourteen years is the minimum life of a patent in normal circumstances.

It may be mentioned that these fees are the same as have been in force hitherto, although under the new Act the Patent Office may subsequently raise them at any time. The maximum fees under the Act were published in our previous article, but apparently there is no likelihood of their being enforced in the near future.

A reminder of the renewal fee being due will be sent to the patentee by the Patent Office at least a month before the date when it becomes due. The renewal fee is to be paid by means of a stamped form duly filled in.

RESTORATION OF A LAPSED PATENT.

If a patent has become void on account of the failure of the patentee to pay his renewal fees, he may apply to the Patent Office for the restoration of the patent. To do this he has to pay a fee of £20 and explain the circumstances which led to the omission of the payment of the renewal fee. He is to accompany this with a statutory declaration verifying the statements made in his application. If the Patent Office entertains the application, an advertisement is published in the Official Journal, and it is free to anyone to oppose the restoration of the patent. The opponent must pay a fee of £1, which is in the form of a stamp on a notice stating the reason for his opposition. The rules as to evidence and hearings are the same as those which apply in the case of opposed patents.

In the event of such a patent being restored, persons who have availed themselves of the subject matter of the patent between the date of the announcement in the Journal of the patent being abandoned and the restoration of the patent are held free from prosecution for infringement or actions for damages, and any such person may even make application to the Board of Trade for compensation in respect of money, time, or labour expended in the *bonâ fide* belief that the patent had become void.

AMENDMENT OF A PATENT SPECIFICATION.

If an inventor desires to amend his specification he must apply on the prescribed form and pay a fee which is £1 10s. if the patent has not yet been sealed or £3 after it has been sealed. The application is to be sent in to the Patent Office, together with a certified copy of the original specification and drawings, with the desired alteration marked on in red ink. A small fee is also payable for the certification of the copy. Particulars of the desired amendment are then advertised in the Official Journal. Any person desiring to oppose the amendment may do so on payment of a fee of 10s. and sending in a form in duplicate stating the reason of his opposition; the duplicate copy is sent to the patentee. A statutory declaration in support of his opposition may be sent in also; similar rules hold with regard to counter-declaration, &c., as in the case of an opposed patent. If the amendment is agreed to, the fact is advertised in the Journal.

A request to correct a clerical error is not regarded as an application for amendment. A special form is provided for the purpose, and the fee payable is 5s. before the patent has been sealed, or £1 after.

PATENTS OF ADDITION.

"Patents of Addition" are introduced for the first time in the new Act. By obtaining a Patent of Addition instead of an ordinary patent for an improvement or modification of an invention which he has previously patented, the inventor is relieved of the necessity of paying renewal fees on the second patent. He has, however, to pay the same fees on depositing the additional provisional and complete specification and on the sealing of the patent of addition (£5 in all). Application for patents of addition must be made on special forms provided for the purpose, and not on the ordinary application forms. A disadvantage is that the patent of addition expires at the same date as the fundamental patent. Modifications or improvements in existing patents can, however, be protected by ordinary patents as heretofore, in which case, of course, the supplementary patent runs for its full life, but the full renewal fees are then payable.

COMPULSORY LICENCES.

If a patentee does not manufacture his patented article to an adequate extent, and supply it on reasonable terms, or if, for other reasons specified in the new Act, "the reasonable requirements of the public have not been satisfied," any person interested may apply for a compulsory licence. The application must be made on the proper form, upon which the applicant must state in detail the circumstances of the case and the terms upon which he asks that an order for a compulsory licence should be made, and he must send in with this another form, stamped with a £1 stamp, requesting the Comptroller to place his application before the Board of Trade. It must also be accompanied by affidavits or statutory declarations and other documents in support of his petition, and copies of all of these must also be delivered to the patentee. The patentee, in opposing the application, has also to put in formal declarations and to pay a fee of £1. He must serve copies of his declarations on the petitioner, who may again reply with another batch of declarations in reply. The Board of Trade will dismiss the petition if no case has been made out; if the Board is satisfied that a licence should be granted, it may assist the parties to come to terms; or, finally, it may refer the petition to the High Court, which may fix the terms for the granting of licences or may revoke the patent.

APPLICATION FOR THE REVOCATION OF A PATENT.

Revocation of a patent may be applied for under two different sections of the Act.

In the one case it is in the event of the applicant for the revocation alleging that he himself was the true inventor or that the patent was obtained by fraud. The fee payable in this case is £2, and the procedure is similar to that in the case of opposition to the grant of a patent.

A more interesting reason for demanding revocation of a patent, recognised for the first time in this country in the new Act, is that the patent is not adequately worked in the United Kingdom. If it can be shown (after August 28th, 1908), in the case of a patent which is four years old, that the patented article is manufactured exclusively or mainly outside the United Kingdom, this is sufficient ground for revocation, unless the patentee can give a satisfactory reason for this. The patent may be revoked by the Comptroller forthwith, or he may make an order that it be revoked at the end of a certain time unless manufacture in the United Kingdom is proceeded with to an adequate extent.

Applications for revocation for this cause may be made by any person interested, and although the fee payable in the first instance is but £2, it will probably be a lengthy and costly process. After the usual deposit of statutory declarations on both sides, the Comptroller may hear the case *viva voce*, and may admit witnesses on both sides. Finally, his decision may be appealed against to the High Court.

THE G.B. SURFACE CONTACT SYSTEM

A LECTURE was given by Professor J. T. Morris at the East London College, University of London, on Thursday, December 19th, in which some details of the working of the G.B. surface contact tramway system were given, with the results of the author's investigations into the working of the stud.

Prof. C. Smith, of the same College, who was in the chair, made a few opening remarks about the line equipped with this system that is being laid along the Mile End Road.

At the commencement of his lecture, Prof. Morris summarised the leading features of the three systems of tramway working. The L.C.C. had adopted a surface contact system in the Mile End Road mainly because the Underground Railway did not leave sufficient depth for their conduit system, and the Borough authorities strongly objected to the overhead system. The only example of the Griffiths-Bedell or "G.B." system is now at work at Lincoln, wher a short line has been in use for nearly two years.

The method of working of the system is roughly as follows :—A magnetised flexible "skate" is carried under the car. As this passes over a stud it is attracted down and makes contact with the stud, and at the same time the magnetic flux causes a switch-piece or plunger to fly out and make contact with the underground live conductor below the stud. This conductor takes the form of a cable constructed largely of iron, and carried on insulators in earthenware pipes. The cable is bare, and therefore liable to electric osmosis. This is guarded against in the following way :—The insulators are reel-shaped, and are threaded on iron spindles. One end of the spindle is made to project outside the pipe. The ends of the spindles are all connected by hoop-iron, with the result that the osmotic action takes place on this instead of on the cable.

The object of the flexible skate is to allow of the studs being flush with the road surface. That the skate rises from the stud quickly enough to clear the road surface when running at high speeds is perhaps doubtful. The skate is made up of a number of cast-iron links, threaded on a flexible cable, and supported by vertical springs in a slot in one pole of a magnet. It is a little over six feet long. Three cores on which the magnetising coils are wound connect to the other pole, which is above. The skate is magnetised normally by current from the underground conductor. A battery of about 25 volts is provided, which is charged when the current is large, and which excites the magnets when the current is cut off. Switches are provided to open the battery circuit when the car is standing.

The stud is made up of a chilled cast-iron plate on top, from which descend two soft iron prongs or cheeks. The plunger or switch-piece is hung up by a spiral spring between these cheeks. The spring is made, in the L.C.C. system, of pianoforte steel wire, heavily coated with copper and covered with a preservative compound. It is insulated, the current being carried by flexible copper conductors. The chances of its breaking and making the stud permanently alive are very small. At Lincoln, from August to December, not a single live stud was found. The plunger is tipped with a carbon block. One of these was shown that had been in use for six months. It showed a slight concavity, but very little roughness.

The distance between the studs is 6 ft. as against 9 ft. at Lincoln. The shorter distance is necessitated by the fact that the cars are required to operate on the conduit system as well as on the surface contact. Only one skate can be used instead of two as at Lincoln, and therefore in order that contact may always be made with one stud, the studs must be much closer.

The theory of the action of the plunger is at first sight not quite clear. Professor Morris attacked the problem, and gave his own ideas on this point. When the cheeks are magnetised, it might be thought that the iron of the plunger would be attracted to them, rather than repelled. But it must be remembered that the plunger is between two N. poles, and is magnetised by lines passing vertically downwards, thus forming a S. pole at the upper end and a N. pole at the lower end. The S. pole is attracted to, and the N. pole repelled by, the two N. poles at the ends of the cheeks, with the result that the plunger moves out. When the cable is in position there is, of course, the additional attraction of the magnetised plunger to the iron of the cable. Professor Morris also looked at the explanation from another aspect, going to fundamental principles. If any part of a magnetic circuit is movable, that part moves into such a position as to allow the maximum number of lines to flow. The magnetism has to leak round from the stud through the air to the upper pole. The area available for leakage is greater with the plunger out than in, especially if the cable is in position to make contact with. It has been proved experimentally that the plunger moves farther with the cable in position than without it. In Fig. 1 a curve is given, showing the total flux through different parts of the stud, and Fig. 2 shows roughly the distribution of the flux. The flux density near the end of the cheeks is about 4,000. The 0·6 ampere curve represents working conditions.

The construction of the cable is ingenious. A centre of jute is surrounded by a ring of copper wires. Then come two layers

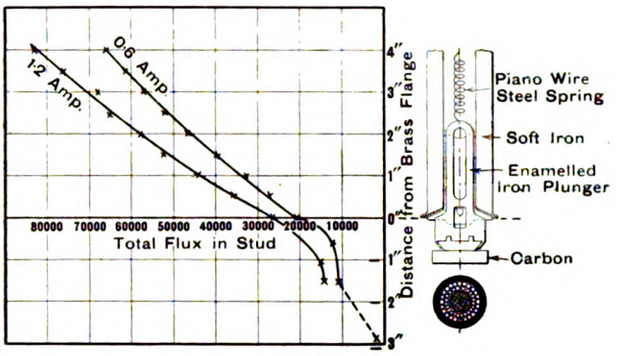

FIG. 1.

of galvanised iron wire, and over all is fitted galvanised iron tubing in 6-in. lengths. The conductivity of the cable is equal to that of a 00 trolley wire. Heavier currents can be carried by a cable of the same diameter (1·2") by putting in more copper and less jute. The iron tubing was not used at Lincoln, but the iron wire did not give a sufficiently good contact.

The joints of the earthenware pipes, which are of an egg-shaped section, are very carefully made. Sticky tape and an iron sheath, filled inside with pitch, is used. The joint is practically water-tight. Any water that may leak in is carried away at drainage pipes fitted at intervals. Every alternate piece of piping has a stalk projecting upwards, into which the stud fits. Two granite blocks which fit round the stud are hollowed out below the road surface. The hollow is filled in with pitch, thus sealing the stud into the pipe. The trench in which the pipes are laid is $16\frac{1}{2}$" deep.

At points, crossings, and other special work, extra precautions have to be taken. It is quite evident that if ordinary iron rails were used when the skate came over the rail it would be attracted and would short-circuit the supply. This is guarded against in two ways. Manganese steel rails are em-

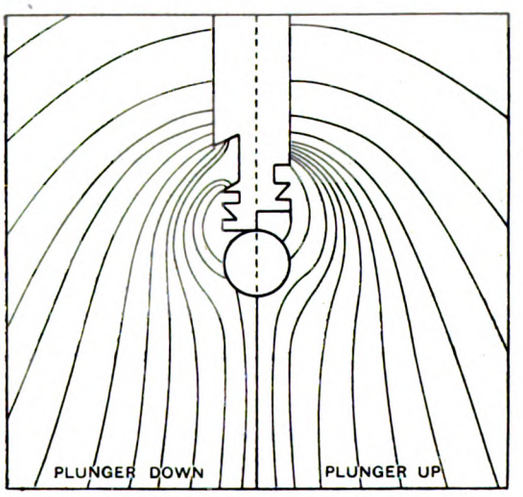

FIG. 2.

ployed. This steel, which consists of 88 parts of iron to 12 parts of manganese, is practically non-magnetic (μ=1·4). Studs of a special type are also used at dangerous positions. In these studs the upper part is insulated from the lower. The two parts are connected through a resistance of 8 ohms, which limits the short-circuit current to 60 amps. (The resistances are placed three or more together in pits under the roadway.) Therefore, should a piece of scrap-iron be picked up by the magnets and trail across a rail and short-circuit the supply, no harm is done.

Every car is fitted with apparatus for detecting a live

Digitized by Google

stud that may be left behind. A steel brush passes over the stud after the skate has left it. If the stud is alive, current is collected by the brush, and either rings a bell or passes through a coil in the canopy switch and opens it, thus stopping the car. The latter system is to be used, we believe, in London. When the car is stopped in this way, the driver closes the canopy switch and drives slowly backwards until the switch is opened again. In this way the live stud can be detected.

Fig. 3 shows the actual forces acting on the plunger. It will be observed that the resultant downward force on the plunger is considerably greater at the commencement of its movement than it is later. This is as it should be, as the plunger is then accelerated more quickly than it would be with a uniform force. Prof. Morris concluded by stating his indebtedness to Mr. Bedell for information and specimens and to certain students of the college for their help in various ways.

The CHAIRMAN, in inviting discussion, remarked upon the greatly increasing traffic in London, and also complimented the inventor upon having succeeded in producing a surface contact system that was in a fair way to success.

Mr. HOLMES next spoke, and questioned the efficacy of the carbon contact when in continual use. In reply to this, Mr.

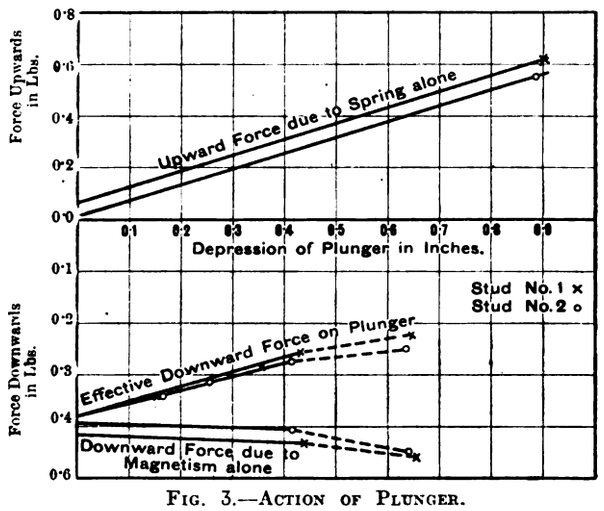

FIG. 3.—ACTION OF PLUNGER.

Bedell produced a block that had been in use for six months. He asked other questions that have been already dealt with.

Mr. MURPHY asked how this surface contact system compared with the overhead and conduit systems as regards cost of installation. He upheld the use of the spring as against gravity. The utilisation of gravity necessitates that the moving part should have considerable mass, which was unfavourable to quick motion. He also asked what was the loss in the magnet winding. He thought it possible that the rubbing of the skate over the studs would have an appreciable braking effect.

Mr. FARMER asked how the skate was insulated from the car. Several other speakers asked questions.

Prof. MORRIS replied that the surface contact system costs, on the average, about 10 per cent. more than the overhead, while the conduit system costs close upon double.

Mr. BEDELL spoke next, and stated that some of the information given that evening was new to him. He said that the actual pull between the skate and the stud had been adjusted to 3 lb. The adjustment was made by varying the ratio of pole face and chain face. The tractive effort required was therefore 7 or 8 oz., and quite negligible. The magnet was attached to the car body by insulating bolts.

Manchester Electrical Exhibition.—We are informed that Mr. H. Talbot, President of the Municipal Electrical Association, has accepted a seat on the Exhibition Committee to represent their interests and those of the Nottingham Corporation, who are supporting the scheme.

Electric Lighting Dispute in Toulon.—We understand, from the *Daily Chronicle* special correspondent, that a conflict between the Socialist municipality of Toulon and the local electric light company threatens to have a serious ending for the city. The municipality at the moment owes the company £16,800 for the lighting of Toulon. For over a year the council has been repeatedly "dunned" by the company, but, for reasons best known to itself, has refused to pay. Now, as a result of legal proceedings, a bailiff has been placed in possession of the town hall, and the plaintiff company has given the mayor and councillors a week in which to find the whole of the debt, failing which the electricity will be cut off, and Toulon will find itself left in darkness.

THE BERJONNEAU SYSTEM OF ELECTRIC TRANSMISSION OF PICTURES

From our Paris Correspondent

LAST Saturday evening a demonstration was given by M. Pascal Berjonneau of his new system of transmission of pictures before a large audience in the hall of the Société des Ingénieurs Civils. After giving a full description of the system, the working of which is outlined below, experiments were conducted under the following conditions. The sending and receiving instruments were first connected to a loop formed of the State telegraph lines from Paris to Marseilles and back, a total distance of 1,726 kilometres, when several pictures, including a portrait of M. Simyan, Under-Secretary of State for Posts and Telegraphs, were successfully sent and received at the rate of one in each fifteen minutes. In the second experiment the apparatus was disconnected from the line and operated by Ducretet wireless telegraph relays. It had been hoped that the "wireless" station on the Eiffel Tower would have been used, but the authorities were unable to grant the necessary permission on account of the Lorient-Paris-Casa Blanca experiments of the French Navy being in progress. The sending and receiving apparatus had therefore to be placed in the same hall, but this in no way detracts from the importance of the experiment, in which it is claimed that pictures were transmitted by wireless methods for the first time.

The system of M. Berjonneau differs fundamentally from that of Prof. Korn (ELECTRICAL ENGINEERING, Vol. II., page 767), in that selenium is not made use of, and may be said to present the following advantages of both the Korn system and that of M. Belin (ELECTRICAL ENGINEERING, Vol. II., page 845):—Greatly reduced size of apparatus and greater robustness of mechanism; the use of the same apparatus for transmission and receiving; the possibility of working over the longest land lines or submarine cables, as the only line current is the very small amount required to actuate relays; and, finally, the possibility of wireless transmission. Roughly speaking, the Berjonneau transmitter is nothing more than a Morse key actuated in a particular manner, sending a series of current impulses which are translated in the proper manner by the receiving apparatus. First of all, a copper relief similar to the blocks used for printing "half-tone" reproductions of photographs is prepared from the original which it is desired to transmit. This is made in the form of a cylinder, and mounted on a travelling revolving drum similar to that of a phonograph, with a feed of 1/6 mm. per revolution. In place of the sapphire "needle" of the phonograph, a suitably insulated platinum point is employed, which makes contact with the portions of the cylinder standing in relief and causes currents depending in duration on their size, but of constant strength, to be sent into the line.

In the receiving apparatus a sensitive film is mounted on a similar cylinder, and a ray of light passing through a very small aperture is caused to fall on it as it rotates. A diminutive shutter, actuated by an electro-magnet, controls the incidence of the ray according to the current received, so that light falls on the film only at points corresponding to those of high relief on the sending cylinder. On development, therefore, a reproduction of the original photograph is formed in fine lines 1/6 mm. apart. It will be seen that the strength of the current does not enter into the question, so that the whole of the working can be done by relays either over a telegraph wire or by "wireless" methods. The main point of importance is the accurate synchronism of the cylinders; but we have not at present information as to how this is obtained.

TRANSMISSION LINES AND THIRD RAIL EQUIPMENT OF THE WEST SHORE RAILWAY BETWEEN UTICA AND SYRACUSE

THROUGH the courtesy of the British Thomson-Houston Co., Ltd., we are able to give some interesting details of the electrification of the West Shore Railroad of the Oneida Railway Co. between Utica and Syracuse, which forms a good example of the latest American practice in continuous-current traction. To give some idea of the conditions to be met, we may mention, before proceeding to a description of technical detail, that the service to be handled over the length of 44 miles of route is as follows, in addition to the steam freight service still maintained over the line:—(1) The fast limited cars or trains will leave each terminal hourly, and make two stops en route. These will complete the journey in 1 hour and 28 minutes, the 28 minutes being taken on the local lines at each end of the system, the run over the West Shore track proper taking only 60 minutes. (2) Local cars or trains with a schedule speed of 24 miles per hour, which will complete the run in 1 hour and 58 minutes, will also provide an hourly service from each terminal, and will make frequent stops at every highway if necessary.

The general scheme of electrification provides for the generation of current at 2,200 volts at Spiers Falls, where it is stepped up to 60,000 volts, and transmitted to the sub-stations. At the sub-stations, after this pressure is reduced to 370 volts, it is converted to direct current, and fed to the third rail at 600 volts.

The transmission line is of special interest, being operated at so high a pressure as 60,000 volts, and may be described in some detail. The Hudson River Electric Power Co. is erecting a transmission line from Spiers Falls to Clarks' Mills sub-station, the other three sub-stations being supplied with energy by the transmission line constructed by the Oneida Railway Co. The two transmission lines are radically different in details of construction, although they both operate at 60,000 volts, and supply three-phase current at a periodicity of 40 cycles per second. The Hudson River Power Co.'s transmission line, which, when complete, will be in duplicate throughout, extends from Spiers Falls to Utica. It is 100 miles in length, and passes through Ballston Spa., Amsterdam, Johnstown, St. Johnsville, and Little Falls *en route*. The general shape of the towers will be seen in the illustration. They are built of galvanised steel angles. The towers are all of the same general type, but vary in weight according to the requirements of the line, and there are three different arrangements of cross arms and insulators.

The standard towers, used on tangents and in all places where the angle of deflection is less than 20 degrees, weigh 4,200 lb. each, and have an ultimate breaking strength of 8,000 lb. The transposition towers weigh 5,600 lb. each, and are designed to stand the same strain as the standard towers; such transposition towers are placed 2¾ miles apart. The corner towers are of a much more substantial construction, weighing 10,000 lb. each, and have an ultimate breaking strength of 17,000 lb. Such towers are only employed where the angle of deflection is greater than 20 degrees. The normal spacing of the towers is 550 ft., but the distance is variable, depending largely on the contour of the ground, some being placed 750 ft. apart, and others not more than 400 ft. apart. The average number of towers per mile is ten.

The conductors are composed of six copper wires stranded on a hempen centre, forming a cable with a capacity equivalent to that of a No. 000 solid wire, and having a diameter of half an inch. The breaking strain of this cable as shown on test is about 6,100 lb. The conductors are spaced so as to allow a clearance of 6 ft. between them at any point in the span which necessitates the spacing of the insulators always being somewhat greater than 6 ft. A ground wire of the same material and of the same size is strung for the entire length of the line, and is grounded at every fourth tower to a galvanised iron plate 20 in. × 30 in. The insulators are constructed with four petticoats; they stand 15½ in. high, and at their greatest diameter measure 18 in. Each insulator weighs about 45 lb., and when assembled was subjected to a test of 140,000 volts. Both the upper and lower cross arms are built up of 3 × 3 × ⅜ in. angles, and are suitably braced. The upper arm is 11 ft. 9 in. in length, and the lower 17 ft. 9 in. The foundations are built of concrete, and extend to a depth of 5 ft. below surface of the ground. The bases of the towers occupy the four corners of a 17 ft. square.

The Oneida Railway Co.'s transmission line is not in duplicate, but consists essentially of three conductors, each having the capacity of a No. 0 wire; the cables are built up of seven strands of hard drawn copper. No form of lightning protection is used other than that provided in the sub-stations themselves. The cable is strung from tower to tower with a sag of 12 ft. for a span of 480 ft. at 30 degrees Fahrenheit. This corresponds to a normal tension of 300 lb. in the cable, and if the spacing of the towers varies, the sag is altered to bring this tension up to the constant. The Oneida Co.'s towers assume a square lattice structure which is composed of four 3 × 3 × $\frac{5}{16}$ in. angles. The legs of the towers are buried 5 ft. deep in re-enforced concrete footings which have a section of 3 ft. × 10 in. In designing these towers, a side wind pressure amounting to 1¼ lb. per linear foot of cable is allowed. This figure is based on a wind pressure of 30 lb. per linear foot on the flat surfaces, and half of that pressure on the round surfaces when the cable is covered with a coating of sleet equal to its own diameter. A maximum pull of 1,000 lb. per cable is allowed on a single cross arm tower, the ties being designed to break at this tension. The height of the tower is such as to allow a minimum clearance of 10 ft. over buildings or wires that may be crossed by the transmission line. At those points where the transmission line turns through an angle, the towers are provided with a sufficient number of insulators to enable the curvature of the wire at any one insulator being kept within an angle of 7½ degrees.

The insulators are of porcelain, and it is of interest to note that no rigid specifications were prepared by the railway company as to the tests, dimensions and materials which should be adhered to in their design. The manufacturer was simply asked to construct insulators which they could guarantee to operate satisfactorily at 60,000 volts, with the happy result that since the line has been erected and tested, no failures have been recorded. The insulators are spaced 7 ft. apart at the corners of a 7-ft. equilateral triangle, and are mounted on malleable iron pins 18 in. in height by means of cement. The pins are attached to the cross arms by four ⅝-in. bolts, and are designed to withstand a strain of 2,000 lb.

There are in all four sub-stations situated at various points along the line, equipped with transformers, rotary converters, and switchgear, manufactured by the General Electric Co., of Schenectady. The equipment of these is, generally speaking, on what has come to be regarded as standard lines, except for the high voltage of the incoming lines, which necessitate special care being taken to provide the necessary clearance on the high-tension side. The transmission lines enter the building under weather-proof hoods, and the openings in the wall through which the wires pass are 3 ft. in diameter.

The high-tension room is constructed with the required number of compartments isolated from one another by suitable barrier walls; those on the outside wall housing the lightning arresters and choke coils, and those on the inner wall serving as bus-bar compartments and to isolate the oil switches, each leg of which occupies a separate compartment. The bus-bar compartments occupy the lower portion of the inner wall and the oil switches are situated about 16 ft. above the ground floor level; a floor having been built at this height throughout the high-tension compartment to provide a ready means of inspecting the switches and lightning arresters.

The rotary converters are of 800 kw. capacity, and are designed for 40 cycles instead of the more usual 25 cycles. Batteries are not used on the traction circuit, but a few cells are installed in the sub-stations for auxiliary purposes.

The most interesting feature of the railway is the underrunning protected third rail, of which a total length of some 105 miles has been laid. The form of rail employed is of the bull-head underrunning type, and is of the same cross-section as that employed on the electrification section of the New York Central Railway.

The weight of the rail is 70 lb. per yard, and it was supplied in lengths of 33 ft. In the case of the New York Central rail, a special composition was used to secure the highest conductivity possible, but in the present instance this was unnecessary owing to the traffic conditions, which are not of such a nature as to demand so heavy a current. The third rail adopted on the West Shore Road is of the Lackawanna Steel Co.'s standard composition for track rails of from 70 to 80 lb.; that is to say, they consist of carbon 0·45 to 0·55, phosphorus not over 0·10, silicon not over 0·20, and magnesia not over 0·75 to 1·05. A rail of this composition and cross section will give an electrical resistance of 0·0494 ohms per mile, or, in other words, the rail

Digitized by Google

has a conductivity equivalent to a copper cable of 1,023,000 c.m. cross section. This conductivity is sufficiently large, so that no D.C. feeders will be required.

The general form of protection and the method of attaching it to the third rail will be seen in the illustrations; part of this protection is in the form of a wooden sheath and part in the form of a fibre sheathing. The wooden protection is of

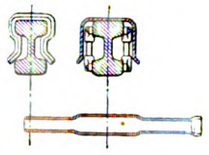

FIG. 1.—FIBRE SHEATHING.

long leaf yellow pine in three parts:—teh top and two base pieces, which are held together by 3½-in. diamond pointed drive screws. The wooden covering is not subjected to any special treatment, but is painted before being applied to the rail. The fibre sheathing is illustrated in Fig. 1. It is moulded in lengths of 43½ in., and it takes three sections of this length to cover the third rail between brackets. The joints on straight track are covered by 2½-in. lap joints, while the joints in the wooden protection are butt joints. On those stretches of track where the fibre covering is used, the rail joints are protected by a fibre covering of wider section, and in this way the bands are very effectually protected, and where the wooden protection is used it is cut away to accommodate the splice bars, bolts, and bonds. The specifications for the fibre sheathing called for an insulation test of 5,000 volts before breakdown. The covering is sufficiently flexible to permit its being pressed into position.

The third rail is normally situated between the tracks, but at all curves this order is reversed, and the third rail is installed alongside the running rail of greater radius. The location of the third rail relative to the track will be seen by reference to the illustration. This position does not conform with the dimensions that have been advised as standards for such work, but it was dictated by the fact that both passenger and freight cars of practically every type in existence are required to be accomodated. The location selected for the third rail will permit the passage of all types of cars with the very limited exception of a special design of coal car which has low truss rods. At each yard a cast-iron tell-tale is provided, which is used to ascertain if there is any projection on the train which would interfere with the third rail.

The brackets for supporting the third rail are of tough grey cast-iron, and the specifications required that a sample piece of

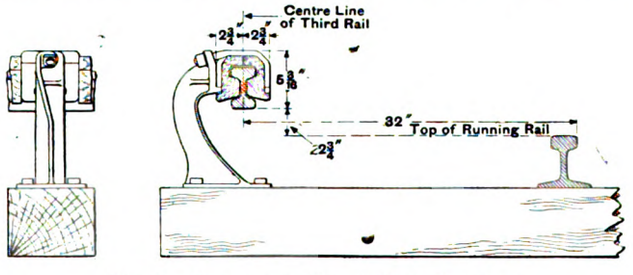

FIG. 2.—DETAILS OF THIRD RAIL BRACKET.

1 sq. in. cross section, cast from the same heat of metal in sand moulds, should be capable of sustaining a central load of not less than 2,500 lb. on a clear span of 12 in., and that such test pieces should deflect 0·15 in. before rupture.

These brackets are shown in detail in Fig. 2, and it will be noticed that they are of the same pattern as that adopted on the New York Central electrification. They are located 10 ft. apart, or on every fifth tie, long ties having been provided in all necessary places along the track, with this exception, that at such points as where switches and other special track construction would involve too much expense in laying new ties under a multiplicity of rails, a length of channel iron is bolted to the end of the tie, and the bracket is bolted to this channel. To insure a standard position of the bracket being adhered to throughout the whole construction a template was used for drilling the holes in the ties, which was held over the running rail and against the tie, while the holes were being marked out. Brackets are held to the ties by means of three lag screws ¾ in. in diameter and 4½ in. long.

The insulators for holding the third rail in the brackets are of semi-porcelain. A great deal of consideration was given as to what material should be used, as to secure good insulating qualities vitrification is necessary, but at the same time a thoroughly vitrified block is necessarily brittle, which makes it unsuitable for third rail construction. The necessary combination of mechanical strength and electrical insulation has been obtained by using a combination of clay and porcelain mixture and by subjecting this composition to special methods of drying and burning. The insulators were required to pass the follow-

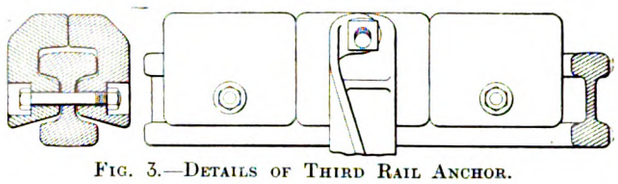

FIG. 3.—DETAILS OF THIRD RAIL ANCHOR.

ing tests:—(A) They should be immersed in water for 72 hours, then removed, and the surface wiped dry, and the resistance of the insulator measured from the hook slot to the rail slot, should not be less than 10 megohms. When subjected to a precipitation of ¾ in. of water per minute the resistance measured as before shall not be less than 0·2 megohms. (B) A compression test with the pressure uniformly distributed should show the insulator capable of withstanding at least 85,000 lb. without showing any indication of fracture. (C) For tensile strength all insulators should be capable of standing a stress not less than 1,400 lb. without showing any indication of fracture. (D) The impact test is of special interest. It provides that 2 per cent. of each batch of insulators shall be selected and subjected to a test consisting of successive blows from a ¾ lb. weight in the form of a spherical steel ball dropped from a height of 50 in. The insulators not showing any signs of fracture after 100 such blows shall be rated as 100. Other insulators shall be rated at the number of blows at which they develop fracture. The average of these ratings must not fall below 25 blows.

The insulators are held in their respective brackets by a steel hook bolt, which passes around the insulator and through a lug on the top of the bracket. This will be seen more clearly by reference to the illustration. The third rail is anchored at frequent intervals. This is accomplished by two wooden insulators bolted to the third rail on either side of a porcelain insulator. The illustration of this will show that the bolt passes through the wooden insulator and the third rail, which effectually prevents any longitudinal movement of the rail. The wooden insulators are of the same general shape as the porcelain insulators.

The third rail approaches or inclines are made of grey cast-iron of the same quality as specified for the third rail brackets, and they are attached to the third rail by a standard two-bolt splice

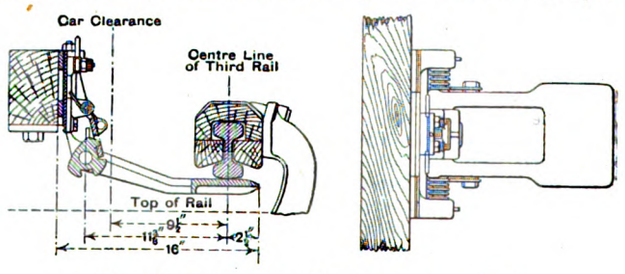

FIG. 4.—DETAILS OF UNDER-RUNNING SHOE.

bar. These inclines are used at all breaks in the third rail, and their general form and the special third rail covering used in their protection are shown in a comprehensive manner by the illustration. The insulators used for their support differ from the standard insulators only in that they are slightly shallower in order to meet the special requirements.

The third rail jumpers are used at all breaks in the third rail to insure a continuous conductor. They are housed in an iron pipe 3 in. in diameter. The cable, before being drawn into the iron pipe, is insulated with 3/32 in. rubber, and is enclosed in lead. The jumpers are brought up to about 2½ in. above the surface of the ties, and the cables, after emerging from the ducts, divide in two twisted arms, commonly known as pigtails, which are attached to the third rail by means of solid copper terminals, which are bolted and soldered. Great care is exercised to protect the terminal at the point where it emerges from the duct; it is tapped and painted, and the end of the duct is also plugged with oakum to prevent dirt from entering, and to avoid any movement of the cable. The third rail joints are made in the ordinary manner by means of two-bolt splice bars secured in position with bolts ⅞ in. in diameter.

Digitized by Google

The third rail is bonded throughout with 15″ ribbon bonds, which are soldered to the rail at each side of the upper head and have a large contact surface at each joint. They each have a capacity of 500,000 c.m. As already stated, where the wooden covering is used it is cut away to accommodate the bonds and with the fibre covering a special section is used to cover the joints.

The third rail is continuous throughout under normal operation, the only sectionalisation being at the feeder points opposite each sub-station. This arrangement is of the simplest possible nature, and permits any section between the sub-stations being cut out by means of the switches on the feeder panels at the adjacent sub-stations.

The running rail is bonded throughout with 11 in. bonds with compressed terminals which are located under the fish-plates. There is only one bond at each joint, but they have a section equal to that of a 4/0 trolley wire. The track is cross-bonded at all special work, such as cross-overs and switches.

There are at present fifteen cars, of the interurban type, in operation, each equipped with four 75 h.p. motors, and Sprague-General Electric multiple-unit control. The arrangement of the underrunning shoe is shown in Fig. 4.

WIRELESS COMMUNICATION OVER SEA

MR. J. ERSKINE-MURRAY read a Paper with the above title recently before the Institution of Engineers and Shipbuilders in Scotland. Although the principal subject of the Paper was electrical wireless telegraphy, the introduction contained a short survey of marine communications in general, including systems of signalling by sound transmitted both through air and water and by light.

A technical description of the apparatus used in any system of wireless telegraphy was not attempted, but the author confined his remarks to its application to nautical purposes and to the general principles which define its scope and the advantages and disadvantages of the various systems at present in use. In order to indicate the magnitude of the wireless telegraph system of communications throughout the world, the following data collected from various Government and other reports on the subject were given :—

Commercial land stations	195
Merchant vessels	170
Lighthouses, &c. (Government stations) ...	150
Naval installations	670
Military portable installations	55
Experimental stations	310

These 1,550 stations have been erected by the various companies in approximately the following proportions :—

Telefunken	41 per cent.
Marconi	20 ,,
De Forest	6 ,,
Lodge-Muirhead	3 ,,
Fessenden	3 ,,
Other systems	27 ,,

As regards commercial land stations :—

Marconi	32 per cent.
Other systems	68 ,,

On merchant vessels :—

Marconi	56 per cent.
Other systems	44 ,,

The figures, which are more complete than those given in the American report abstracted on p. 841 of ELECTRICAL ENGINEERING, November 28th, were given to show that the adoption of the Radiotelegraphic Convention by this country was a necessary consequence of the refusal of the Marconi Companies to allow their stations to intercommunicate with those of other companies whether on sea or land. The actual proportions in different regions are, of course, very various. On the North Atlantic the Marconi Company has a greater hold than elsewhere, though it is very far from having a monopoly, even in the British Islands. In South America, the West and East Indies, and on the Continent of Europe, excepting Italy, the Telefunken, Lodge-Muirhead, and De Forest Companies practically do all the business.

The general principles of wireless telegraphy were summed up shortly, as follows :—The energy which transmits the signal is propagated over the earth's surface as an electric wave motion. This wave motion, or alternate current, may be either uniform like an ordinary lighting or power current, or it may be in the form of damped wave trains, *i.e.*, in short series of waves following one another at comparatively long intervals; each series or train commencing strongly and dying out after comparatively few waves. In the first case a high frequency alternate current generator or a vibrating electric arc may be used; in the latter, the intermittent spark discharge of a condenser. In both cases it is necessary that the frequency of the current (number of alternations per second) should be high in order that the amount of electricity set in motion at each wave, and, therefore, the actual dimensions of the apparatus, may not be too large. This will be appreciated when it is recollected that a small quantity of electricity, or any material, when moving very rapidly, may transmit a large amount of energy. (A high speed de Laval steam turbine is a good mechanical instance of this.) A high frequency is thus advantageous from an engineering point of view, though it is not absolutely necessary.

The receiving apparatus must, therefore, be capable of detecting and indicating currents whose frequencies are greater than 100,000 per second. There are now scores, possibly hundreds, of ways in which this may be done. These may be classed as follows :—(*a*) Imperfect electrical contacts, or coherers, whose resistance is changed by the action of the received current; (*b*) Electrolytic detectors, which indicate the received currents by an alteration in polarisation; (*c*) Thermometric detectors which indicate the current through the effects of the change of temperature it causes; (*d*) Magnetic detectors in which the magnetic state of a piece of magnetised iron is altered by the current; (*e*) Electromagnetic detectors on the current balance, or electro-dynamometer principle; (*f*) Valves or rectifiers which, owing to their property of permitting current to pass more easily in one direction than in the other, produce a more or less unidirectional and, therefore, measurable current directly from the alternating current received; (*g*) A miscellaneous class whose methods of action have not yet been explained.

The best known forms of coherer are (1) the Marconi, consisting of a glass tube of about 5 millimetres bore, in which are two silver plugs about 0·5 millimetre apart, between which a small quantity of very fine nickel filings are placed. The gap is usually V-shaped to admit of regulation by merely turning the tube as the filings only occupy about one-third of the space and are, therefore, more or less crowded together according as the wide or narrow end of the V is uppermost. (2) The Lodge-Muirhead, which consists of a razor-edged steel wheel about the diameter of a threepenny bit whose edge dips into mercury covered with oil, and which is kept revolving by clockwork. The Marconi coherer, which, by the way, is a modified form of Branly tube and is also used by the Telefunken Company, requires to be decohered by tapping or shaking it after it has recorded a signal, as it would otherwise remain cohered. This, though apparently a disadvantage, is in reality the essence of its success, for it is owing to this that it was first possible to maintain the effect of the passage of the high frequency current long enough to obtain from it a permanent record of the Morse tape by means of ordinary telegraph instruments. The Lodge-Muirhead coherer is decohered after a small fraction of a second by the movement of the wheel.

The other detectors most in use are Marconi's magnetic detector and the electrolytic or barretter invented by Fessenden. Magnetic detectors are based on the fact that a high frequency current, even if of very short duration, may produce considerable changes in the magnetism of a fine magnetised iron wire. In Marconi's form an endless band of fine iron wires is kept travelling round two pulleys. Surrounding one of the straight pieces between the pulleys is a small glass tube on which are wound two coils of fine insulated wire. One of these is connected to the aerial and earth wires, and the other to a telephone receiver. Two permanent magnets are placed so that their lines of force include part of the travelling iron band in their circuit. The motion of the band draws the lines to one side through the retentiveness of the iron for magnetism. The high frequency current in the aerial wire, on passing through the small coil round the iron band, suddenly demagnetises it, or rather releases the lines of force. These spring back into a position at right angles to the band, and in so doing cut the coil connected to the telephone, induce a current in it, and thus produce an audible click in the instrument. The motion of the band soon draws the lines aside

Digitized by Google

again and renders the apparatus ready to indicate a new signal. The Morse "dash" is, of course, represented, as in all systems of wireless telegraphy, by a close succession of dots.

The electrolytic receiver, or barretter, depends on the fact that if a constant voltage be applied between electrodes dipping into an electrolyte, one of which is of very small area, the current is, under certain conditions, unstable, and the sudden superposition of a high frequency current causes a sudden and considerable increase in the constant current. The action is not yet properly understood, though many theories have been stated. A telephone is generally used in connection with this detector which is one of the most sensitive of all.

It is noticeable that in the above list of detectors of high frequency currents there are very few, if any, which give directly an audible or visible indication of the signal. In practically every case it is thus necessary to have some auxiliary instrument to indicate to the operator that the detector has reacted. In some cases a telephone, syphon recorder, or Morse inker, may be used at will, in others the telephone is the only auxiliary suitable, and it is, therefore, not possible to obtain a permanent record of a message.

The waves are propagated outward from the transmitting station, either equally in all directions or with a maximum in one direction according as the aerial wire is vertical or inclined. In the latter case the strongest transmission is in the direction of the lower end of the wire. This method is used at Clifden and Glace Bay, Marconi's transatlantic stations, and at Knockroe, the Poulsen transatlantic station now building.

The lines of electric force are in general attached to the ground and follow it, as they do a wire in ordinary linear conduction. The resistance and dielectric constant of the ground are important factors in determining the distance to which it is possible to signal with any given transmitter and receiver. In general the dielectric constant is the more important of the two, and the chief reason why it is more easy to transmit signals over water than land is that the dielectric constant of water is 80, while for dry sand or rock it is only about 5. Thus it is possible to transmit signals very much further over water with a given power than over land. The actual ratio of the distances is now calculable approximately in cases where the natures of the soil and subsoil are known.

It is now easy to determine with considerable accuracy, in fact within a few degrees, the direction from which a message is coming—a discovery which may in the near future become a great aid to navigation, since any two land stations within range of a ship will be able, by making simultaneous observations, to give their bearings, and thus to fix the actual position of the vessel. In these days of ever-increasing speeds it is becoming more and more essential that the shipmaster should be warned, when still a considerable distance away, of his approach to land. This has been done for some years by wireless telegraphy, but it is only recently that it has become possible to add to the warning a statement of the actual position of the ship at the time of sending.

The speed of transmission at moderate distances, and the reliability of a wireless connection, are now both as good as the same qualities in an ordinary land wire. A proof is given by the abolition of the Post Office wire from Hunstanton to Skegness, since wireless stations have been erected, and the fact that a speed of 90 words per minute has been attained between these stations. The means of preventing interferences between neighbouring stations have been developed to such good effect in the last few years that it is now possible, as experience shows, to construct apparatus which will respond only to waves which do not differ by more than about 4 per cent. from the proper wave length for the station. An even greater sharpness in tuning has indeed been claimed by various workers, and may very probably have been obtained. A margin of 4 per cent. is, however, sufficient to render possible the efficient working of a very large number of stations in a comparatively small area without interference. The actual wave lengths to be used by ships and shore stations have been fixed in some countries; and in all which are parties to the International Convention, the wave lengths from 600 to 1,600 metres are reserved for naval purposes; wave lengths below 600 metres being available for short distance stations, and those above 1,600 metres for long range stations. The usual wave length for short distance stations (*i.e.*, under 100 miles range) is about 400 metres. The German long distance station at Nauen uses wave lengths of 2,000 metres; Poldhu (Marconi) of about 2,500 metres, and Clifden of about 4,300 metres.

The Paper concluded with a short reference to the progress of wireless telephony in the American navy, and a table of wireless telegraph stations in the United Kingdom, similar to that given in ELECTRICAL ENGINEERING, November 28th, page 841, was given in an appendix.

THE WESTINGHOUSE METAL FILAMENT LAMP PATENT

A PATENT of considerable interest, published last Friday by the Patent Office, is No. 18,923 of 1907, taken out by the Westinghouse Metal Filament Lamp Co., Ltd.

The invention relates to improvements in the methods of securing metallic filaments of incandescent electric lamps to their leading-in conductors by the use of a metal alloy serving as solder, produced at the junctions of the filaments with the leading-in conductors, and also involves a novel process for producing the same.

By this method the filament is durably fastened in intimate contact with the leading-in conductor.

The process is based upon the fact that certain metals, such as aluminium, magnesium, calcium, cerium, and the like, have the characteristic property of giving out energy when combined with oxygen, for which they possess a great affinity.

When, therefore, a metallic oxide is mixed with aluminium, magnesium, or other similar metal, and the mass is heated at one point, the reaction is initiated and will then continue without further assistance. Inasmuch as the reaction gives out considerable heat, bodies, especially metallic ones if introduced into such a mixture, can be highly heated, and under proper conditions can even be brought to their melting point.

The invention is carried out in the following manner :—

The ends of the leading-in conductors are provided with hooks or loops, or other suitable means for receiving the filaments, and the filaments are thrust into or secured to these. A mixture is prepared of metal oxides, preferably of such metals as are to be fused together, and to these oxides, aluminium or magnesium, calcium, cerium, &c., is added, as nearly as practicable in equi-molecular proportions, with a suitable liquid or flux, and the connecting points are covered with this mixture, carefully dried and heated to initiate the reaction; this can be effected by means of the electric current or with the help of any other heating source.

The liquid or flux employed should be such as will not exercise an injurious effect upon the material, thus, for example, with calcium instead of water, alcohol, or some other organic compound should be used, and on the other hand with aluminium, a solution of mercuric chloride or some other suitable salt of mercury may be used.

The reaction which takes place proceeds in the well-known manner, and by reason of its positive or exothermic nature, causes the bodies to be combined to fuse together into an alloy which constitutes a reliable contact. In the course of the reaction, oxide of aluminium, magnesium, &c., is also produced, which forms a film on the outside of the joint. This does not in any way affect the conductivity of the joint, and may easily be removed if desired by dipping into hydrochloric acid.

The claims are :

1. A durable conducting connection between the metallic filaments of incandescent electric lamps and the leading-in conductors consisting of a metallic alloy produced at the point of connection.

2. A process for producing a durable conducting connection between the filaments and the leading-in conductors of incandescent electric lamps consisting in covering the junction of the filament and leading-in conductor with a mixture of one or more metallic oxides and metals which combine with oxygen with evolution of heat, with or without the addition of a suitable liquid or flux, then drying, and finally heating the same for the purpose of initiating the reaction.

4. A process for producing a durable conducting connection between the filaments and the leading-in conductors of incandescent electric lamps in which the oxides of those metals of which the filament and the leading-in conductors consist are mixed with aluminium, or magnesium, calcium, cerium, or the like, preferably in equi-molecular proportions, and applied to the joint, being afterwards heated to initiate the reaction.

Wireless Telegraphy.—It is announced that a complete wireless telegraph service will be installed during January between Marseilles and Algiers.

Telephones for Submarines.—A telgram from Cherbourg to the *Eclair* (Paris) states that as the result of experiments carried out in the first Channel flotilla with a view to providing submarines with buoys fitted with telephonic apparatus in order to enable the crews to communicate with the surface in case of accident, the Minister of Marine, after hearing the evidence of the Technical Committee, has ordered the adoption of metallic floats of great buoyancy, and capable of withstanding the pressure of water at a depth of fifty metres. These floats have been experimented with at Cherbourg on the submersible boat Aigrette, and when practicable they will be fitted to all vessels in commission or in the dockyards as speedily as possible.

THE ELECTRICAL EQUIPMENT OF THE BURBACHER-HÜTTE IRON AND STEEL WORKS

THE introduction of the large gas-engine for the utilisation of blast-furnace gases has, especially in Germany, given a great impetus by the cheapening of power production to the application of electric driving in iron and steel works. An interesting example of an equipment of this nature is found in that of the Burbacher-Hütte, of which, through the courtesy of the Siemens-Schuckert Company, we are able to give some illustrations.

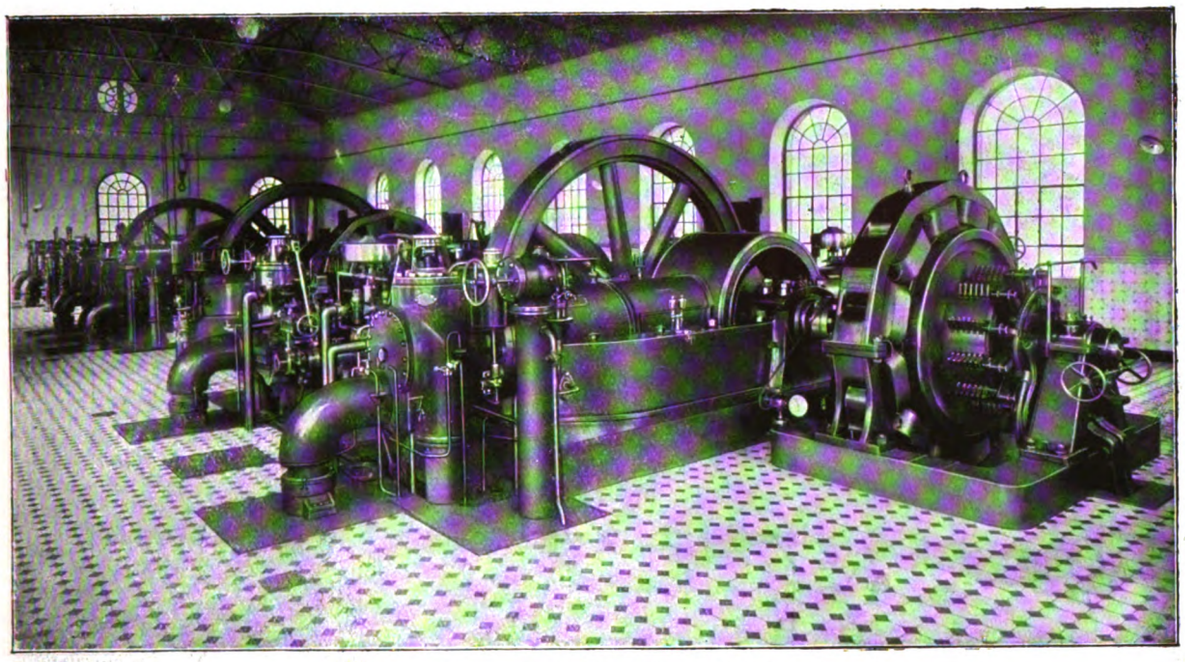

FIG 1.—OLDER GAS-DRIVEN GENERATING STATION.

In Fig. 1 is shown a view of the interior of the older power station, in which are installed three blast-furnace gas-engines of the Deutz type, to each of which is direct coupled a continuous-current dynamo. The output of each set is 1,740 amperes at 240 volts, or about 420 kw., and they run at a speed of 140 r.p.m. The current from these machines is taken through cables placed under the engine-room floor to a four-panel switchboard not shown in the illustrations.

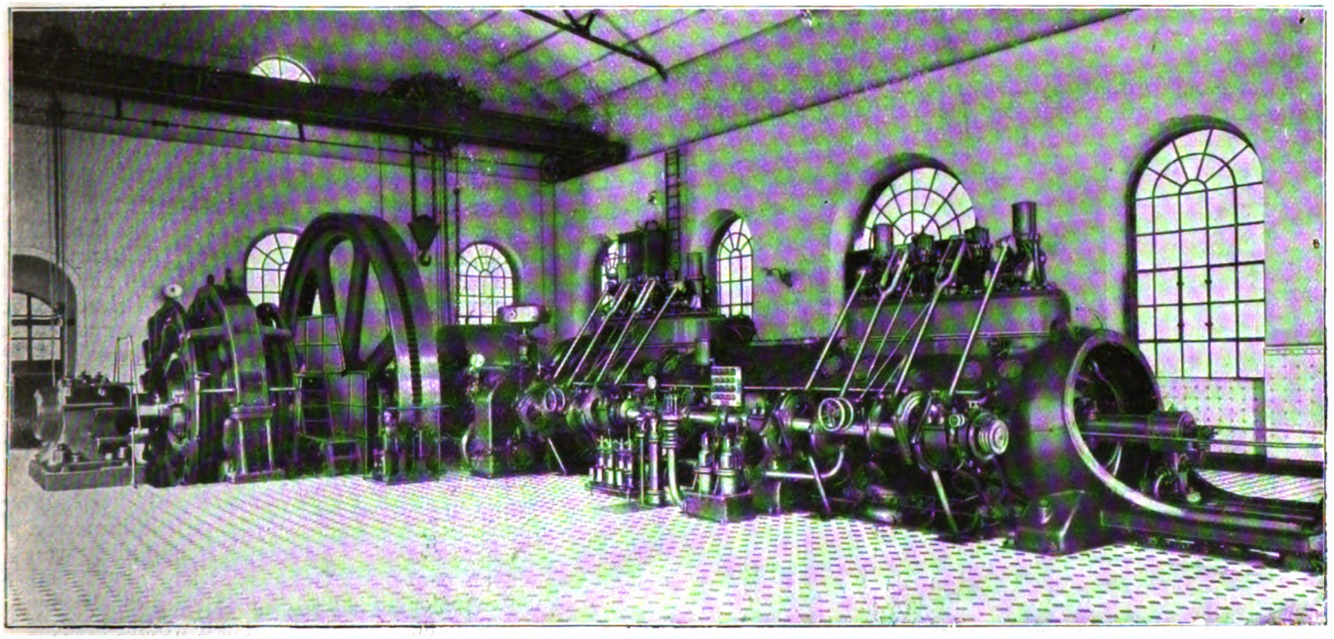

FIG. 2.—NEW GENERATING PLANT.

On account of the extensions in the adoption of electrical driving in the Burbacher Steel Works during 1906, it became necessary to provide further generating plant, and accordingly an entirely new power house

Digitized by Google

was built of ample size for dealing with present and future extensions. The new station was, first of all, set to work with a single generating set, consisting of a continuous-current dynamo directly coupled to a large tandem gas engine by the Augsburg-Nurnburg

FIG. 4.—CONTROLLERS FOR MOTORS OF LIVE ROLLS AND TRAVERSING TABLE.

Co., also running on blast-furnace gas. The electrical portion of plant, as in the older station, was supplied by the Siemens-Schuckert Co. An illustration of the set is given in Fig. 2. The dynamo is a two-commutator three-wire machine, following a practice more common on the Continent than in this country. It is designed for 2 × 240 volts and 2 × 2,045 amperes, or 980 kw., and runs at 100 r.p.m., which is about the usual speed of gas engines of this size and type.

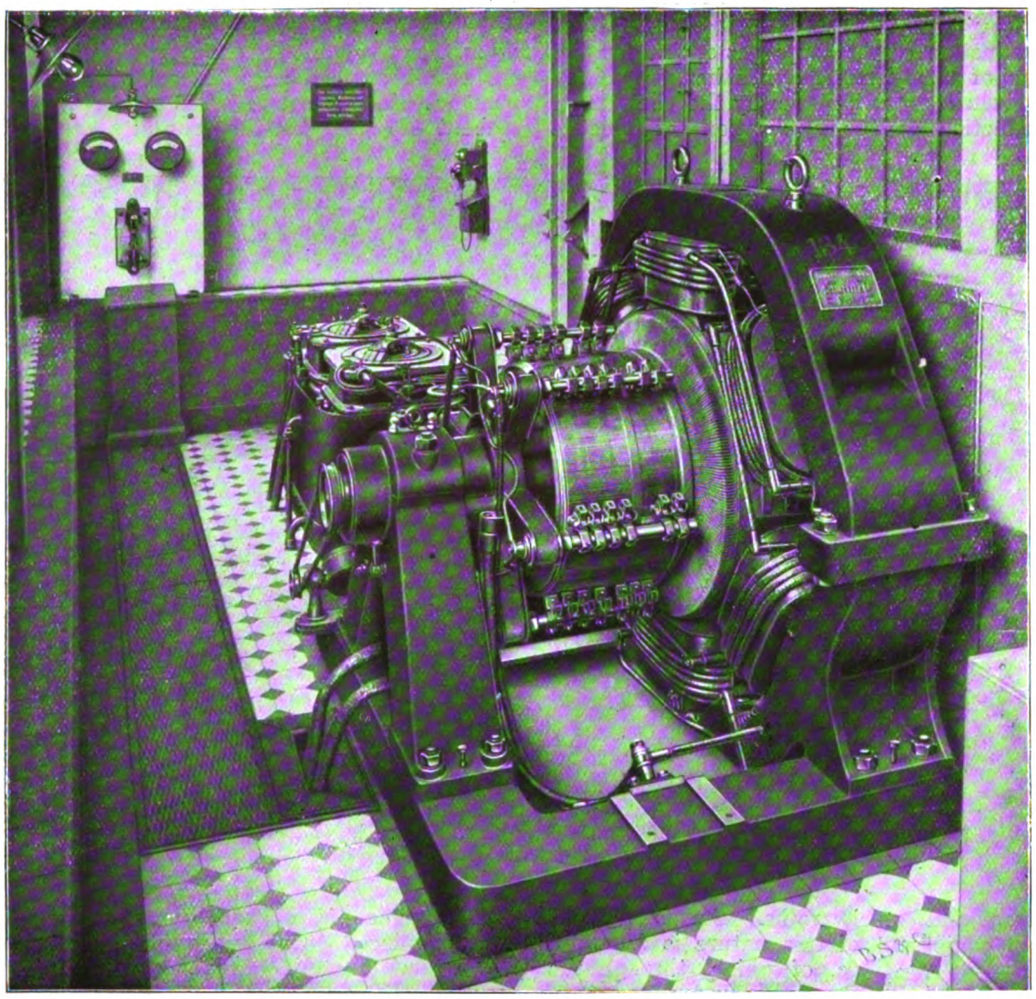

FIG. 3.—MOTOR FOR ROLLING MILL.

In order to further increase the output of this station a set was ordered, to be driven by a steam turbine of the Augsburg-Nurnburg Co.'s manufacture, with a capacity of 1,250 h.p., and running at 1,550 r.p.m. The electrical part of this set, which by this time is probably running, consists of two Siemens-Schuckert generators each for an output of 420 kw., coupled in tandem. These generators, like that of the large gas-driven set, are two-commutator machines for 2 × 240 volts. By means of this arrangement it is possible to supplement to same circuits as supplied by the old 240-volt station, and to also take advantage of the increased economy of the higher voltage between the outers.

The Burbacher-Hütte was one of the first iron and steel works where electrical driving of rolling mills was adopted. As an example of the electrically-equipped mill may be mentioned a set of fine rolls driven by the 6-pole continuous-current compound-wound motor, shown in Fig. 3. This motor has a continuous rating of 410 h.p., but can exert 800 h.p. for short periods to overcome the sudden demands for power often made by the conditions of rolling-mill work. The cycle of operations of this particular mill requires a certain amount of speed variation of the rolls. This is effected entirely by regulation of the current in the shunt

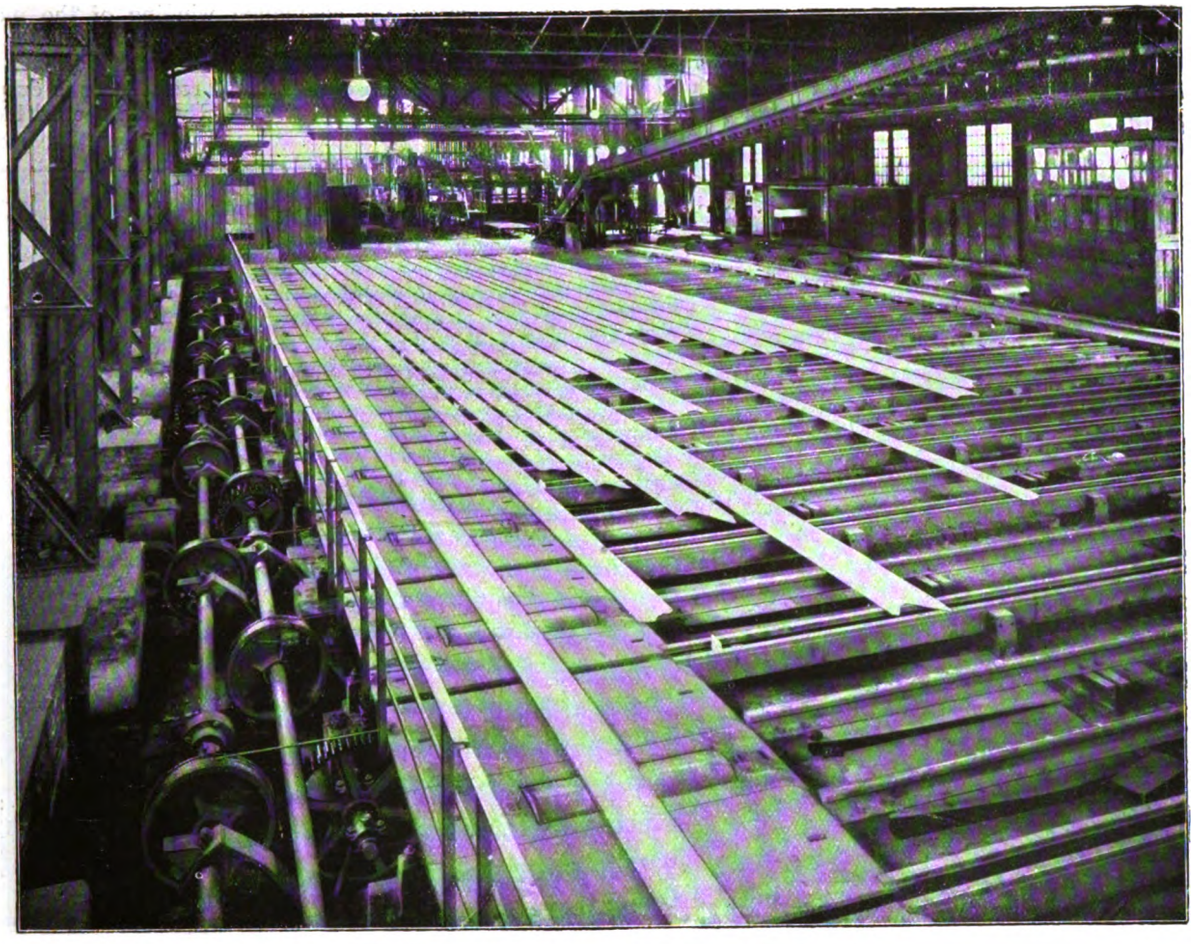

FIG. 5.—LIVE ROLLS AND TRAVERSING TABLE.

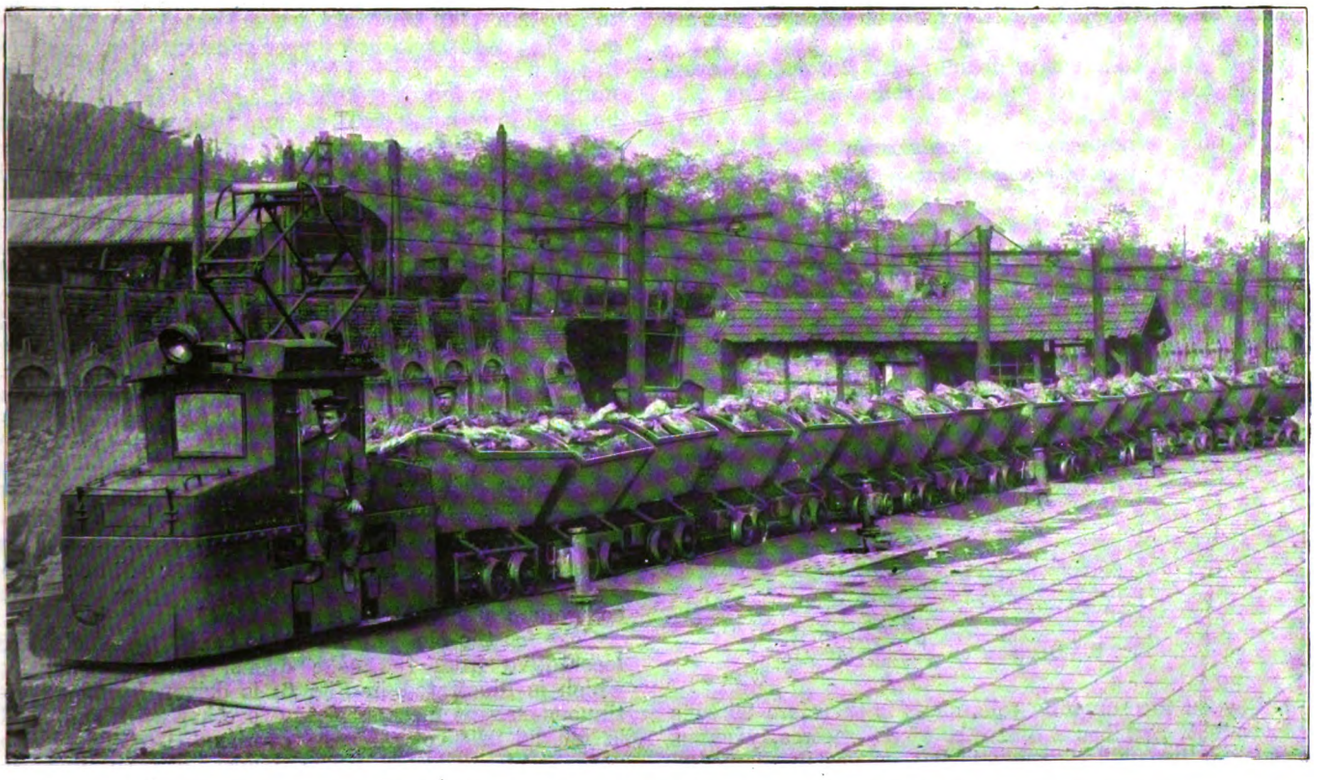

FIG. 6.—ELECTRIC LOCOMOTIVE FOR TRANSPORT OF COKE.

Digitized by Google

winding by means of a rheostat of sufficient size to regulate the speed between the limits of 230 and 300 r.p.m. The motor is coupled directly to the high-speed series of finishing rolls through a leather belt flexible coupling of the Zodel-Voith type. The slower-running

this reason: the compound winding of the motor is proportioned so that when running light the speed is about 10 per cent. higher than at full load.

A starter with oil-immersed resistances is employed, the contacts of which are fitted with a special blow-out

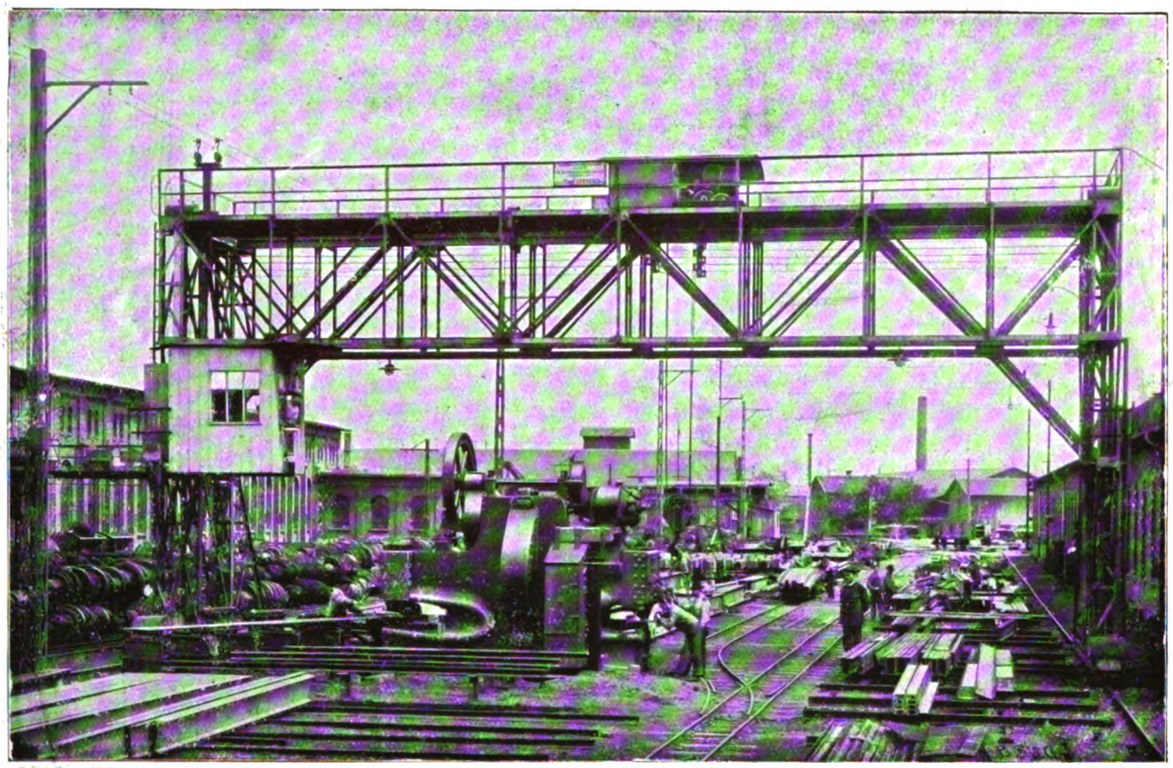

FIG. 7.—PUNCHING AND SHEARING MACHINE AND ELECTRIC CRANE.

roughing rolls are rope driven from the shaft of the finishing rolls by seven 47-mm. ropes of square section. Both the pulleys on which these ropes run are specially heavily built in order to give plenty of fly-wheel effect to assist in dealing with the sudden overloads to which both trains of rolls are liable. The

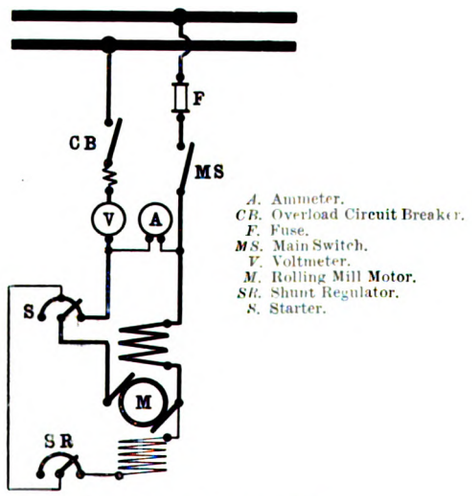

FIG. 8.—DIAGRAM OF CONNECTIONS.

pulley on the roughing rolls shaft is therefore 35 tons in weight, and has a diameter of 6·5 metres, whereas the smaller pulley, which is 2·6 metres in diameter, weighs 7·5 tons. For a satisfactory utilisation of the fly-wheel effect it is necessary that the speed-running light load be higher than when heavily loaded, and for

arrangement. The conditions at starting are, of course, much more severe than in most classes of work, owing to the large masses to be accelerated, so that the starting gear has to be of very substantial proportions in order to carry the full load current for a considerable number of minutes. The starter is also designed to be capable of being used at frequent intervals without overheating. The arrangement of connections of the motor switch gear is shown in Fig. 8. A circuit breaker with overload release is included in one pole of the armature circuit to protect the motor from excessive overloads. Electrically-driven shears between the roughing and finishing rolls cut off the material into convenient lengths. The mill is capable of dealing with billets from 80 to 200 kilogrammes in weight and 130 mm. × 130 mm. section, and is employed to produce round or square bars from 8 mm. to 45 mm. diameter, strip up to 60 mm. in width, and various other profiles such as angle-iron, tee-iron, and channel-iron in the smaller sizes, in quantities from 20 to 50 tons per 12-hour shift. Enclosed reversing series wound motors are used to drive the various trains of live rolls and traversing tables, on account of the high-starting torque required. One of these is shown in Fig. 5. The motors are controlled from a raised platform having a full view of the work. Some of the controllers are shown in Fig. 4.

Coke for the blast furnaces is brought by an electric locomotive from the coke ovens. This locomotive, which is illustrated in Fig. 6, is driven by two continuous-current motors, giving together 25 b.h.p., and is fed at 220 volts by an overhead line through a pantagraph collector. The gauge of the line is 630 mm., and its length is about 1·8 kilometres. A considerable number of these locomotives are in use for the transport of ore, coal, and other materials.

Digitized by Google

Further applications of electrical driving are shown in Fig. 7, which illustrates a shearing and punching machine in the open air, driven by a 20-b.h.p. 220-volt compound-wound motor, and served by a travelling electric crane. The total number of motors installed in the works is 290, giving, in the aggregate, 2,550 h.p. For the lighting, over 4,000 incandescent lamps, and 300 arc lamps are employed.

BRAKE GEAR DESIGN

A PAPER by Mr. F. Heckler was read recently before the American Central Electric Railway Association dealing with some mechanical points in the design of brake gear for electric railway and tramway cars, and considering more particularly brakes worked by compressed air. An abstract of the Paper is given in the *Street Railway Journal* (New York).

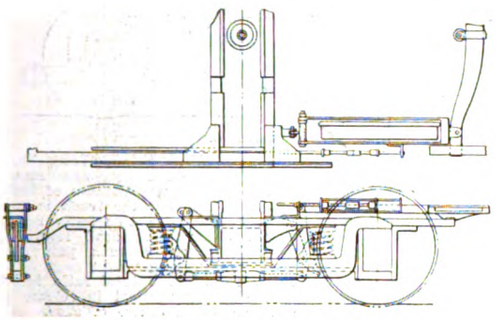

FIG. 1.

Truck and Brake Design. Merits: 1. Inside hung brake shoes. 2. Equalised brake leverage system, so that unequal shoe clearance will not throw all the pressure on one pair of wheels. 3. Radius bar connection to live truck levers. Besides its use on curves the radius bar construction eliminates the great deflection of weak brake beams, due to the truck levers acting at their centre.

Demerits: 1. High truck leverage ratio. The total ratio is 7.22 to 1, and necessitates a large movement of the live truck levers in setting the brake shoes, with consequent danger of fouling something. The multiplication can readily be made in the car-body levers where there is greater clearance room. The total truck lever ratio should not exceed 6 to 1. 2. Angle of live truck levers almost vertical in release position.—If lever is too near vertical in release position, it assumes a bad angle when brake shoes are set up against wheels. 3. Available movement of radius bar too limited. 4. Brake shoes hung slightly too far below the centre of wheels.—This will increase in proportion to the load. 5. Dead lever dimensions not of the same proportion as those of the live truck levers.—One pound applied at the middle of radius bar gives 3.53 pounds pressure at the live lever brake shoes, and 3.69 pounds at the dead lever shoes. This results in unequal shoe wear, and also makes it impossible to use the best percentage of braking power on both pairs of wheels.

The brake is usually looked upon as a safety device only, and it is because of the prevalence of this idea that the installation and maintenance does not receive the consideration it merits. There is no part of the railway equipment that will give greater material returns than the brake when properly installed, operated, and maintained. Its importance would be more fully appreciated if we could eliminate the idea that it is a safety device only, and show that it makes possible the hauling of heavier cars, and faster and more frequent service as much or more than the high-power motor, the signals, and the good roadbed. If given the consideration it should have, it would increase the possibilities of all these things. Therefore, at least the same consideration should be given to its design and installation that is accorded to other parts of railway equipment. The magnitude of the problem can be seen when the thought is kept in mind that the brake has often to do in seconds what it has taken the motive power minutes to accomplish, and that it is far more important to be able to stop a car than to start it. No matter how perfect and well maintained the apparatus may be, a great part of the brake efficiency may be lost by improper design of foundation brake gear, which condition will continue to exist until the brake ceases to be looked upon as a necessary evil. When it is realised that the brake equipment is not merely a necessary expenditure, but a dividend-earning asset, then sufficient pressure will be brought to bear on the car and truck designers and builders to induce them to consider the brake installation before it becomes impossible to put on one that will even merit the name of a brake in the true sense of the word.

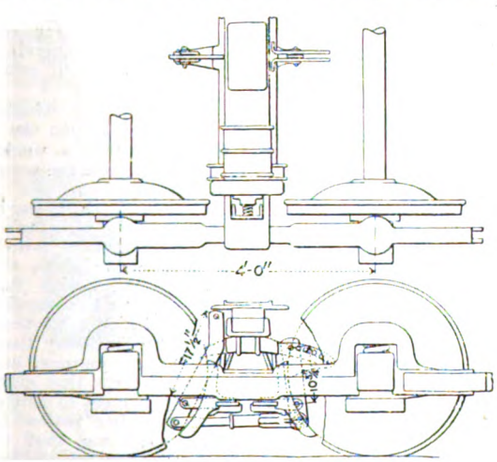

FIG. 2.

Truck and Brake Design. Merits: 1. Inside hung brake shoes. 2. Equalised brake leverage system.

Demerits: 1. Very high leverage ratio. The total ratio is 10.96 to 1. 2. Brake shoes hung somewhat too far below centre of wheels. 3. Dead lever dimensions not of the same proportion as those of the live truck lever.—One pound applied at the top of the live lever gives 5.37 pounds pressure at the live lever brake shoes and 5.59 pounds at the dead lever shoes. 4. Dead lever fulcrum should be horizontal instead of curved. 5. Dead lever is too short, thereby assuming a bad angle with the brakes set, especially with worn shoes. 6. Angle of main truck lever too near the vertical in release position.

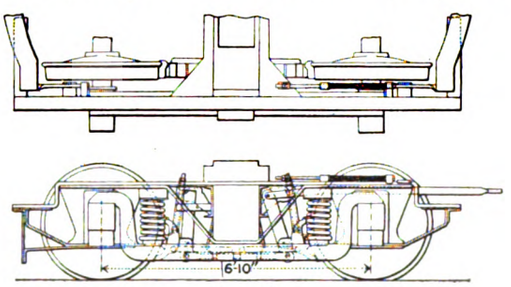

FIG. 3.

Truck and Brake Design. Merits: 1. Inside hung brake shoes. 2. Equalised brake leverage system. 3. Good angle of live lever in release position. 4. Radius bar connection to live truck levers.

Demerits: 1. Very high truck lever ratio. The total ratio is 9.85 to 1. 2. Dead lever dimensions not of the same proportion as those of the live truck lever.—One pound applied at the middle of radius bar gives 5 pounds pressure at the live lever brake shoes and 4.8 pounds at the dead lever shoes. 3. Brake shoes hung somewhat too far below centre of wheels. 4. The suspension is at upper end of shoe instead of at centre of same.

The brakes should be given equal consideration with the other necessary points of design, for at all times much money will be made thereby, and there are times when not money, but life and limb, become the measure of this value.

Coming to the mechanical requirements of the foundation brake gear, the most desirable features in connection with this

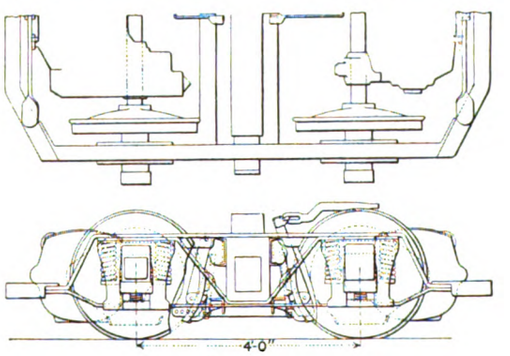

FIG. 4.

Truck and Brake Design. Merits: 1. Inside hung brake shoes. 2. Equalised brake leverage system. 3. Good angle of live lever in release position.

Demerits: 1. Very high leverage ratio.—The total ratio is 10.8 to 1. 2. Brake shoes hung somewhat too far below centre of wheels. 3. Dead lever dimensions not of the same proportion as those of the live truck lever.—One pound applied at the top of the live lever gives 5.33 pounds pressure at the live lever brake shoes and 5.46 pounds at the dead lever shoes. 4. Shoe hangers so straight as to preclude proper release by gravity action when pressure is removed.

Digitized by Google

matter are a motor truck that will permit a brake design providing a low truck leverage ratio and a clear movement of the same for the entire wearing out of the brake shoes of, say, 1½ in. thick; also provision in motor truck construction for the best location of the brake shoes on the wheel and the suspension of the brake head or beam hangers at a proper angle, and at such a point on the truck as will maintain a standard location of the shoes on the wheel, regardless of whether the car is light or loaded. These recommendations also apply to the car builders who, in many cases, so design the car body portion of the foundation brake that the harmonious working of the hand and air brakes is not possible. In fact, it is seldom that a car and truck design can be found upon which even a passable brake installation can be made.

To the end that improvement be made in this direction, the following suggestions are offered. In the design of the car and truck ample space should be allowed for the application of the proper brake equipment and a suitable foundation brake gear right down to the brake shoes.

Sufficient clearance should be allowed to permit of the wearing out of the shoe, and, in the event of piston travel adjustment being neglected, the piston should strike the cylinder head before the radius bar or levers foul.

While a total leverage of from 9 to 1 to 12 to 1 is proper, yet

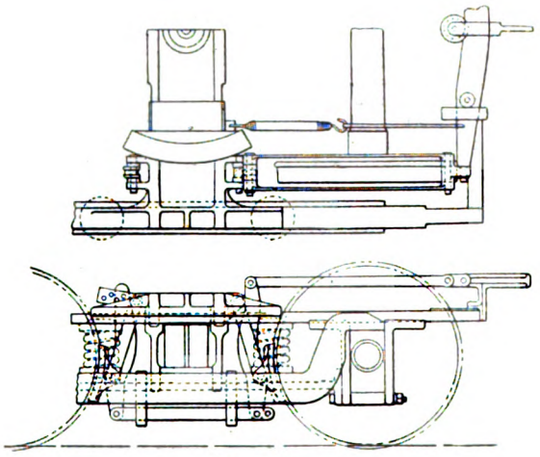

FIG. 5.

Truck and Brake Design. Merits: 1. Inside hung brake shoes. 2. Equalised brake leverage system. 3. Radius bar connection to live truck levers. Demerits: 1. High truck leverage ratio.—The total ratio is 7.5 to 1. 2. Angle of live truck levers too near the vertical in release position. 3. Available movement of radius bar in guide too limited. 4. Brake shoes hung slightly too far below the centre of wheels. 5. Dead lever dimensions not of the same proportion as those of the live truck levers.—One pound applied at the middle of radius bar gives 3.7 pounds pressure at the live lever brake shoes, and 3.8 pounds at the dead lever shoes.

the total truck leverage ratio should not exceed 6 to 1, *i.e.*, one lb. exertion on truck pull rod should not give more than 6 lb. of force distributed at the four wheel shoes. This means a ratio of 3 to 1 for each truck lever, but 2½ to 1, or a total truck leverage ratio of 5 to 1, is preferable. This because when it is exceeded, the travel of the top end of the lever becomes great as compared with shoe wear; also, the shoe has to be placed very low on the wheel, besides the danger of the lever fouling on the shoe; also the lower the ratio the less change of lever angle for a given shoe wear.

Proper provision should be made for maintaining as near a uniform piston travel as practicable, that (1) the air consumption may be kept low; (2) that uniform braking power may always be had; and (3) a brake of full power assured at all times.

All truck levers, brake beams, clevises, pins, and rods for truck should be made strong enough to withstand safely the stresses produced with a total braking power on the shoes equal in lb. to the maximum weight of car for which the truck is suitable. This also applies to car-body pins, rods, and levers.

The following points should also be considered:—Release springs of proper strength; thickness, area, and friction of brake shoes; the ratio of leverage to allow for motor and idle axles, ample provision for take up of shoe wear, slack, &c.; elimination as far as possible of lost motion in journal boxes, pin holes, centre plates, &c.; reasonably long truck centres to admit of proper connection of body levers to truck levers by means of pull rods; the equalisation and gearing ratio of the hand brake, so that a large force can be applied to the hand brake chain with small amount of chain to be wrapped up.

Attached are drawings showing designs for truck with brake rigging. These are intended to give some idea of what should be considered in the design as well as to show that many things have not been considered, and for easy references the defects and merits have been printed thereon. Some of them show that the efficiency of even a good brake may be reduced to a minimum and become a source of trouble and loss. Others show that what the brake is expected to do is more nearly

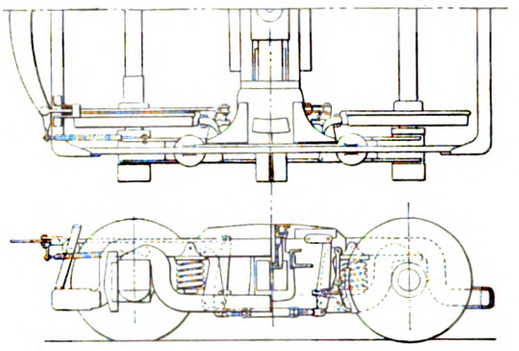

FIG. 6.

Truck and Brake Design. Merits: 1. Brake shoes hung the proper amount below centre of wheels. 2. Brake shoe hanger bracket supported by the equaliser bars.—With this construction the distance of brake shoes below centre of wheel remains constant, whether the truck is supporting the car body and its varying load, or not. 3. Inside hung brake shoes. 4. Equalised brake leverage system. 5. Live and dead levers of same proportion, thus giving same shoe pressure on each pair of wheels. 6. Radius bar connection to live truck levers.

Demerits: 1. High truck leverage ratio.—This total ratio is 7.48 to 1. 2. Angles of live truck levers too near the vertical in release position. 3. Shoe hanger connected above instead of at centre of shoe.

NOTE.—Absence of the thickness and width of truck levers, rods, &c., makes it impossible to figure the strength of the brake rigging, but on electric railway trucks, generally, it is almost invariably too weak, with consequent deflection, and often failure of the brake rigging.

approximated, care and maintenance reduced a minimum, and troubles eliminated.

It is to be regretted that we do not have more desirable truck designs, but they are so scarce as to be practically unobtainable, while undesirable designs can be seen under any car you may care to examine. As these problems are physical, mathematical, and mechanical, it is certainly not beyond the range of possibility that they may be solved in a way that will be satisfactory to the car and truck builders, profitable to the railway companies, and more conducive to the comfort and safety of the public.

The Electrification of the Victorian Railways.—Mail advices received on Saturday state that on November 26th a conference took place in Melbourne between the Federal Postmaster-General, the Chairman of the Victorian Railway Commissioners, and Mr. Merz, the Consulting Electrical Engineer to the Victorian Government. The last named made it clear that the electrification of the suburban railway lines would be begun very soon, and that the effect of the installation of the electric traction plant would render the telephone service, as it at present exists, practically useless, and that an expense of £100,000 would have to be incurred by the postal authorities to instal a complete metallic circuit. Mr. Mauger (the Postmaster-General) stated that he would recommend the Federal Cabinet to consent to the necessary work being carried out.

L.C.C. Tramway Accidents.—Two tramway accidents, fortunately not attended with loss of life, occurred upon the system of the London County Council during Christmas week. The first, and most serious of the two, took place on the evening of Christmas Day, when a covered top deck car got out of control soon after commencing the long descent which starts near the reservoirs in Pentonville Road and ends at King's Cross Station. Pending the Board of Trade inquiry, which will probably be delayed somewhat owing to the holidays, the only reason assigned for the accident is that the brakes failed to act. The work of converting the tramways in Pentonville Road is not completed beyond King's Cross Station, and this point has temporarily formed the terminus. Consequently there was another car there preparing for the return journey, and into this the runaway car crashed with such force that eight passengers were more or less injured, although none so badly as to necessitate lengthy detention in hospital. One reason for the comparative immunity from serious injury was that the car kept the metals, and an extraordinary feature of the collision was that the driver of the runaway car, who stuck to his post, was practically uninjured. All the passengers on the stationary car were warned in time to enable them to get to a place of safety. The other accident referred to above happened on Friday, when an electric car from Stamford Hill to Moorgate Street crashed into a horsedrawn tramcar going to Green Lanes at the junction of City Road and Old Street, and here, again, a few people were injured. In this case the collision appears to have been due to the misjudging of distance by one or both drivers.

MERCURY-VAPOUR LAMPS FOR CONTINUOUS CURRENTS

THE Cooper-Hewitt mercury vapour lamp is becoming well known in this country since its introduction by the British Westinghouse Company, but a few particulars relating to the working of the latest continuous-current type may be of interest.

All the forms consist essentially of a sealed glass tube containing a small quantity of pure mercury. Normally the lamp-tube is slightly inclined, and the mercury remains in a pocket at the lower end, where contact is made with it by a platinum

FIG. 1.—COMBINED TYPE MERCURY VAPOUR LAMP.

leading in wire connected to the negative side of the circuit. The arc is started, and the lamp lighted by tilting it momentarily to allow a small quantity of mercury to flow along the tube.

The lamps may be arranged for running singly or two, three, or more, according to the voltage of the circuit. The current taken by all sizes is 3½ amperes, and the three standard lengths of tube of 18, 22, and 45 inches give 300, 350, and 700 candle-power respectively. Each lamp is connected in circuit through a combined inductive and non-inductive resistance, this being

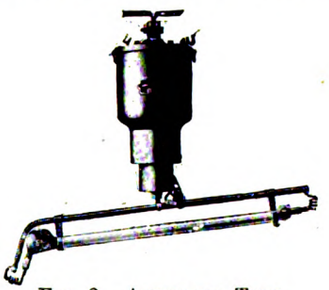

FIG. 2.—AUTOMATIC TYPE.

provided with an automatic shunting device when two or more lamps are to be connected in series, to render each lamp independent of its neighbours. The two chief varieties of lamp are the "combined" and "separate" types. In the former, the resistance coils are contained within the case from which the lamp-holder and lamp are suspended, whereas in the latter type the lamp and resistance are separate.

Another modification is the automatic lamp, in which the tube is tilted automatically by the action of a solenoid when the current

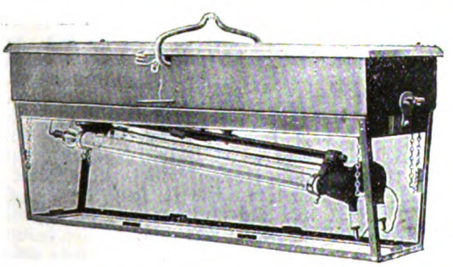

FIG. 3.—AUTOMATIC DOUBLE TUBE TYPE IN LANTERN.

is switched on instead of the lamp having to be tilted by hand. Some of these varieties, including a double tube lamp in a lantern for outdoor use, are shown in Figs. 1 to 4. The three lengths given above, in the case of non-automatic lamps, may be adjusted between the following respective limits of terminal voltage, 50 to 65 volts, 55 to 75 volts, and 100 to 125 volts. The automatic lamps require a slightly higher voltage.

It is of importance in fixing the lamps that the supports should be rigid, so as not to allow of swinging of the lamp, and, of course, care has to be taken to connect the positive and negative poles correctly. Provision is made for adjusting the series resistances so that the lamp takes the current for which it is designed on the particular circuit where it is used. It is well to put an ammeter in circuit and repeat the adjustment whenever a new tube is put into the lamp.

A cross section of the rheostat of a non-automatic lamp suitable for running in series is given in Fig. 5, and a diagram of

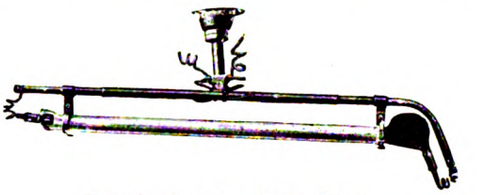

FIG. 4.—SEPARATE TYPE LAMP.

connections of two lamps running in series is shown in Fig. 6. It will be noticed that there are two resistance slides. The one on the right is for the regulation of the shunt current, and is so set that at the normal line voltage the current through the shunt before the lamp is lighted is 3½ amperes. After the lamp is lighted, the adjustment of the main circuit is made by the other slide. The connections of the automatic type of lamp are practically similar with the addition of the solenoid coil for effecting the tilting of the lamp. The shunter contact is arranged to cut the solenoid out of circuit as soon as the lamp lights up. To extinguish the lamp, nothing further has to be done beyond turning off the switch.

The latest pattern of rheostat for use with separate type lamps is shown in Fig. 7, in which the inductance on the left

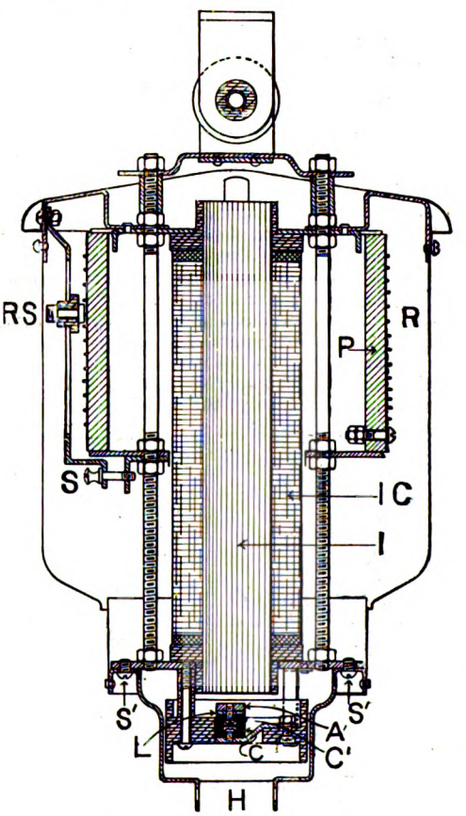

FIG. 5.—CROSS-SECTION OF SERIES RHEOSTAT NON-AUTOMATIC TYPE.

and the resistances with their contact slides on the right are clearly seen together with the shunting mechanism below.

The satisfactory working of these lamps depends very largely on the position of what is known as the "disintegrating point," which is the point at which the current enters the surface of the mercury. This point is continually moving to and fro on the surface of the mercury, and is of very high temperature. The good working of the lamp depends on the purity of the mercury

Digitized by Google

vapour contained therein—that is to say, on the absence of all other gases. In the course of manufacture, the foreign gases (air, &c.) are expelled to as great a degree as possible, but a certain small quantity is always retained by the leading-in wires and the positive electrode.

As long as the lamp works under normal conditions, these solid metal parts do not get very hot, and the occluded gases will not be given off from them. Should the lamp be improperly manipulated, however, overheating of these parts is liable to occur, and in such cases the vacuum of the lamp will be impaired by the liberated gases.

Practically the only way in which this overheating of the metal parts can be brought about is by allowing the disintegrat-

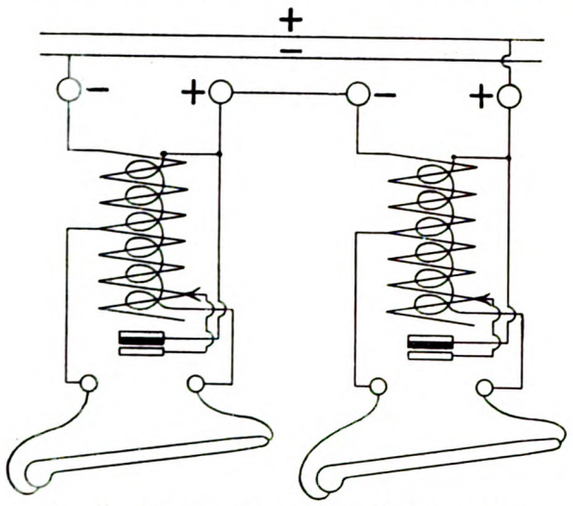

FIG. 6.—CONNECTIONS FOR TWO NON-AUTOMATIC LAMPS IN SERIES.

ing point to attach itself to one of them. The disintegrating point, which—as already mentioned—is at the negative end of the lamp and is of an extremely high temperature, is consequently apt to heat the solid metal very quickly.

To guard against the heating of the lamp electrodes in this way care must be taken that the polarity of the lamp is never reversed, as this would result in the formation of the disintegrating point on the iron electrode at the top end of the lamp. There must also be a sufficient depth of mercury at the negative electrode to ensure its being always covered up, even when the lamp is tilted. For this reason a stop is placed on the holder to prevent the lamp being tilted too far. But, of course, if the lamp is tilted violently, too much mercury may run over.

The disintegrating point enters the surface of the mercury to a depth of about $\frac{3}{64}$ in. In the normal running position there is a protective depth of mercury of about $1\frac{3}{16}$ in., and in the lighting position, that is to say, the position assumed when the

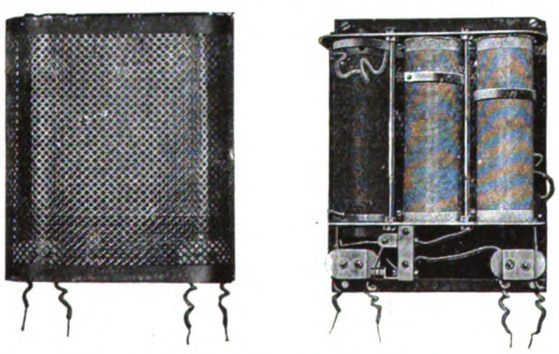

FIG. 7.—SEPARATE TYPE RESISTANCE.

lamp is tilted for starting, there is a protective depth of mercury of about $\frac{5}{8}$ in. If the lamp be kept tilted more than a few seconds, enough mercury will be vaporised to allow the disintegrating point to get down to the top of the platinum wire. This shows how important it is to let the lamp come back to its normal position immediately after it is tilted. If the lamp is shaken violently the mercury is liable to leave the negative electrode exposed, thus allowing the disintegrating point to settle right on the platinum wire. If this occurs only a few times, enough gas will be liberated to spoil the lamp.

In cases where the ordinary lamp tube is fitted in a vertical position, there is a protective depth of only $\frac{3}{16}$ in. of mercury. Under this condition a very slight shifting of the mercury will be enough to allow the disintegrating point to touch the platinum wire. This explains the objection to placing the lamp tubes vertically, as is sometimes done.

The first sign of deterioration is usually that the lamp goes out easily, generally a short time after starting. Another preliminary sign of a bad lamp is that it starts up with a reddish light when cold. This phenomenon is due to the presence of foreign gases in the tube, these gases having been liberated as explained above. When the deterioration of a lamp reaches a more advanced stage, black spots appear on the tube, which finally gets blackened all over.

The normal running of the lamp is secured by :—(*a*) Having a radiating surface to the lamp that is properly proportioned to the current. (*b*) The rheostat.

The rheostat, as previously explained, consists of two essential parts, viz., an inductance or inductive resistance, and an adjustable ohmic resistance. The latter acts primarily as a "buffer" between the lamp and the circuit, in much the same way as the line resistance of an arc lamp, and it enables the current to be adjusted to its proper value. Part of it also acts as a shunt in series lamps.

The function of the *inductance* is to maintain the disintegrating point in an active condition while the lamp is running. This action is reciprocal, inasmuch as the varying resistance of the disintegrating point sets up very rapid variations of the current, with correspondingly rapid variations of voltage in the inductance coil, the effects of which react on the disintegrating point. The interaction of the inductance and the disintegrating point is so rapid that it is considerably affected by *capacity* in the circuit. This explains why it is necessary that the wires running from the rheostat to the lamps, or from lamp to lamp, should be placed at least $1\frac{1}{2}$ in. apart. If the wires are close together their capacity increases sufficiently to annul the above-described action, and the lamp cannot be kept alight.

Paris Metropolitan Railway Accident.—A Reuter telegram from Paris on Tuesday last week stated that an accident occurred on Monday on the Paris Metropolitan Railway at the Rue Lutèce, where a tunnel is being built under the Seine in connection with a new line. The message states that a partition gave way, and the rush of compressed air which resulted hurled the workmen in the caisson under the wall of another caisson, where all five men were drowned.

An Australian Power Plant.—According to the *Australian Mining Standard*, the electrical machinery for the Casilis Gold Mine (Victoria) is being pushed forward very rapidly by the A.E.G. Co., who are endeavouring to have the whole in complete working order before the middle of next year. The plant will consist of a 400 kw. 500 volt. three-phase generator, direct-coupled to a Pelton wheel, of Messrs. Voith's manufacture, capable of developing 670 b.h.p. when running at 500 r.p.m. The set will be capable of withstanding overloads of 25 per cent. The excitation will be carried out by means of a direct-coupled exciter, the voltage of which will be automatically regulated by a Tirrill regulator, so as to maintain constant voltage on the three-phase bus-bars independent of variations in the speed, power factor, or load. As a reserve for the excitation and the lighting, a small continuous-current generator of 10 kw. capacity is provided, driven by a separate Pelton wheel. The governing of these turbines will be carried out hydraulically. With the system of governing adopted, a very high efficiency will be secured at all loads, so that no waste of water will take place during periods of light load, when a storage reservoir will accumulate the surplus water. The water for driving the turbine will be taken from the Victoria River, about four miles above its junction with the Cobungra River, by means of a race about three and a half miles long, sufficiently large to carry water capable of developing 1,200 h.p. at the generating station, which is connected with the race by means of a pipe line 1,650 ft. long, composed of equal lengths of 34 in., 31 in., and 28 in. pipes, giving an effective head of slightly over 400 ft. at the inlet to the turbines. The discharge from the turbines flows immediately into the Cobungra River, at the side of which the generating station is situated. The mine and works of the Cassilis Co. are about 16 miles from the power station; the voltage is raised by means of stationary transformers to 12,000 volts, so that a transmission efficiency of about 90 per cent. is obtained. The energy transmitted from the power station will be conducted to two receiving stations—one at the works equipped with four 125 kw. single-phase transformers, and the other at the mine, with four 35 kw. transformers of the same type. The line voltage will be reduced to 500 for motors. The lighting throughout the mine and works will be carried out by special lighting transformers. The Cassilis installation is of special interest as possessing the longest transmission line in the Commonwealth, carrying the highest voltage.

DETERMINATION OF THE MEAN HORIZONTAL CANDLE-POWER OF INCANDESCENT LAMPS

IN a Paper "On the Determination of the Mean Horizontal Intensity of Incandescent Lamps by the Rotating Lamp Method," published in the United States about a year ago (*The Electrical World*, November 17th, 1906), E. P. Hyde and F. E. Cady described an investigation, undertaken at the Bureau of Standards, of the possible errors of the rotating lamp method. This method is the one in almost universal use in the United States. Another Paper, published by Uppenborn in Munich (*Elektrotechnische Zeitschrift*, February 14th and 21st, 1907), gave results at variance with those obtained at the Bureau of Standards, and this has incited Messrs. Hyde and Cady to return to the subject and carry out further tests.

In the investigation at the Bureau a substitution method was employed, which did not necessitate a determination of the actual candle-power of the lamps studied. Any change in candle-power, due either to the bending of the filament or to the flicker could be detected and measured separately. For most of the types of filaments the effect of bending was to decrease the mean horizontal intensity, but for one type the effect was to increase it by about 1 per cent.

In Uppenborn's investigation the lamps were measured for actual mean horizontal candle-power, by taking the mean of 36 readings made every 10° in the horizontal plane. The values obtained in this way were taken as the true values, and a comparison of the candle-power values obtained by other methods with these standard values gave the errors incident to the several methods studied. In this way eight lamps of different sizes, types, and voltages were measured for mean horizontal candle-power, first by the point-to-point method, and subsequently by the rotating lamp method. A comparison of the results indicated that the values obtained by the rotating lamp method were uniformly too low, the amount of the error ranging from 3·3 to 9·9 per cent. Uppenborn attributed the errors to the distortion of the filament on rotation; but since the experiments at the Bureau had shown in no case an error much over 1 per cent. due to this cause, it seemed desirable to make some further experiments by a different method, and using lamps of other types than those previously investigated. The differences in the results obtained at the two laboratories could not have been due to differences in speed used, for in the experiments at the Bureau various speeds were employed up to 550 or 600 r.p.m., whereas in Uppenborn's work the speed of 450 or 500 r.p.m. was employed.

In the new method the lamp was placed in a universal lamp-holder which could be set at different angles, but which also could be rotated. In general, readings were made first with the lamp spinning, then at every 10° in the horizontal plane with the lamp at rest, and again with the lamp spinning. The speed was then gradually increased, in some experiments until the filament touched the bulb.

The first lamp studied was a 110-volt 16-c.p. oval anchored filament lamp, which was first rotated at about 420 r.p.m., and readings were taken. Then measurements were made every 10° in the horizontal plane with the lamp stationary, and finally the lamp was rotated again at 420 r.p.m. The results obtained by the two methods agreed to within 0·2 or 0·3 per cent., which is within the range of experimental error.

In the type of lamp which was next studied the filament consisted of two long, slender loops, entirely unsupported except at the leading-in wires. Denoting by 1·000 the value of mean horizontal candle-power obtained at the beginning at a speed of 350 r.p.m., the value found by the point-to-point method every 10° was 1·005, and the value obtained at the end at a speed of 350 r.p.m. was 0·999. This decrease of 0·5 per cent. at a speed of 350 r.p.m. was in very good agreement with that obtained in the previous investigation using the rotating mirror method. The mean of a number of determinations using this method indicated a decrease of 0·9 per cent. at a speed of 500 or 600 r.p.m.

Another lamp of the double filament type gave the following results: Mean horizontal intensity at 180 r.p.m., 1·000 at the beginning of the set of measurements, 1·003 in the middle of the set, and 0·998 at the end; by the point-to-point method 1·002, or an average decrease of 0·2 per cent., which also agreed with the values previously obtained for this type of lamp.

Having thus shown that the error at a speed of 180 r.p.m. for this type of filament is negligibly small, the two lamps were mounted successively in the rotator, and the speed was increased until the filaments touched the bulb, in order to see how large a decrease in mean horizontal intensity could be obtained with this type of lamp, and what the speed must be in order to accomplish this maximum reduction.

The maximum decrease in mean horizontal intensity obtained under any condition was about 5 per cent., when at a speed of 750 or 800 r.p.m., the two loops of the filament were each separately touching the bulb, one at one side and one at the other. In no case did the decrease amount to more than 1·5 per cent. so long as the filament did not touch the bulb, but as each loop touched, a decrease in candle-power resulted. The investigators point out that on touching the bulb the filament is cooled, and so a decrease in candle-power is to be expected. Moreover, the amount of the cooling, and, consequently, the decrease in candle-power, depends upon whether the filament touches in only one point, or whether it lies against the glass for an appreciable part of its length, so that the decrease in candle-power is not always the same when a filament touches the bulb.

The double filament lamp seemed to represent one of the worst cases for high-speed rotation, but the large errors found by Uppenborn were obtained with filaments having a turn in them somewhat similar to the common oval anchored filament. It was, therefore, thought desirable to make some tests with lamps of this type.

The maximum error which Uppenborn obtained—9·3 per cent.—was found for a 32-c.p., 110-volt, 1½-turn oval filament with no anchor. The authors obtained two special lamps, which were identical in every respect with the regular 32-c.p., 110-volt, oval anchored lamp, except that the anchor wire was omitted, in order that the filament might be left as unstable as possible. The dimensions of the filament agreed approximately with those given by Uppenborn, the total height of the filament used at the Bureau being about 75 mm. instead of 65 mm., and the vertical axis of the oval being 50 mm. instead of 40 mm.

These two lamps were studied in the same way as the double filament lamps described above, except that the readings by the point-to-point method were made every 15° instead of every 10° as in the preceding determinations. The first lamp was first measured at different speeds up to 600 r.p.m., and the greatest change in mean horizontal candle-power, as compared with the value determined by the point-to-point method, was only 1 per cent. In these determinations the filament did not touch the bulb, although it approached close to it. Subsequently the lamp was kept at a speed of 600 r.p.m. for some minutes, and though at first the filament was separate from the bulb, it gradually spread and ultimately came into contact with the glass. Just before the filament reached the bulb the mean horizontal intensity was about 1 or 1·5 per cent. low; but after coming into contact the intensity decreased to a value 3 or 4 per cent. lower than that determined by the point-to-point method. The current also underwent a very appreciable change when the filament touched the bulb. The speed was now increased to 800 r.p.m., at which both loops were in contact with the glass. The mean horizontal intensity was found to be about 7 per cent. low, and the current to have undergone another change in the same direction as before. While rotating at the high speed of 800 r.p.m. a star crack developed and the filament burned out so that it is possible that a part of the observed 7 per cent. change in candle-power may have been due to the constantly deteriorating vacuum.

The other special 110-volt, 32-c.p. lamp showed approximately the same characteristics as the former, except that the filament touched the bulb first in one point and then in a second point, the mean horizontal intensity decreasing to about 97 per cent. of its original value as determined by the point-to-point method. The current also showed a marked change due to the cooling of the filament.

In addition to the two special 32-c.p., 110-volt lamps, two special 32-c.p., 220-volt lamps without anchors were used. The filaments were of the 2½-turn type, such as are usually provided with two anchors. Without the anchors the filaments were quite unstable and entirely unsuited for high-speed rotation. Consequently, they were forced against the bulb at the comparatively low speed of 400 or 500 r.p.m.

At speeds of 600 or 700 r.p.m., when the filaments were well over against the glass, the decrease in candle-power reached a value as high as 4 per cent. for one of the lamps; but whenever the change in candle-power was large, there was always a very appreciable change in resistance, indicating that the change in candle-power was due probably, to a large extent, to a cooling of parts of the filament. At the high speed of 675

Digitized by Google

r.p.m. one loop was short-circuited by the next, and the filament burned out at the point of contact.

All the data obtained showed, therefore, that the maximum error observed, due to a bending of the filament was not in any case greater than 1·5 per cent., provided the filament did not actually touch the bulb. The speed of rotation necessary to force the filament against the bulb was not less than 600 r.p.m., except for the special 32-c.p., 220-volt lamps without anchors, and for these it was about 400-450 r.p.m. For most common types of lamps the speed would be much higher than 600 r.p.m. and it is probable that for some types a rupture of the filament would occur before the filament would touch the bulb. When the filament touches the bulb changes in candle-power of as much as 6 or 7 per cent. may take place, but as these large changes are always accompanied by relatively large changes in resistance, it is probable that they are due to a cooling of the filament owing to the contact with the glass.

REVIEWS OF BOOKS

How to Design a Gas Engine: with full working drawings for a 7 b.h.p. gas engine. By Horace Allen. 39 pp. 7½ in. by 10 in. 20 illustrations. (Manchester: Scientific Publishing Co.). 2s. 6d.

THIS little work describes the process followed by the author, Mr. Allen, in designing a gas engine to give 7 b.h.p. Full working drawings are given of the engine, and the various parts and calculations are made for all the essential features. The engine produced would work quite well, although there are points in detail which one would like to have seen altered. It is not very good practice, for example, to make the liner shown on page 19 with a contracted part at the breech end. It is always desirable to make a liner so that the boring-bar can be put straight through. Apart from that, it is easier to prevent the accumulation of charred matter at the bottom of the cylinder when the lower line of the cylinder runs clear to the level of the exhaust-valve. This is a small point, but it is important in practice. The construction shown for the gudgeon-pin end of the connecting-rod, too, is not by any means the best in common use. It is very unusual also to make a removable exhaust-valve seating for an engine of such small dimensions. For an engine of this size it would have been better to adhere to the ordinary practice of seating the exhaust-valve directly upon the casting. The construction of separate exhaust-valve seating is not a very good one. In the case of a larger engine it would have been better to allow greater freedom of exhaust discharge. The construction adopted is liable to distortion. Although the engine designed is not quite the best possible from a commercial point of view, it is a good little engine, and Mr. Allen's book contains many interesting discussions on practical points which will be useful to the amateur.

Hints regarding the Management and Use of X-ray Apparatus. By Lieutenant F. Bruce. 50 pp. 6 illustrations. (London: H.M. Stationary Office.) 3d.

THIS little work is a reprint of a series of papers on X-ray apparatus and its management, which have already appeared in the *Journal* of the Royal Army Medical Corps. It is composed of six chapters, the first dealing with the sources of current, the second with the details of induction coils, and so on. The development of the exposed plate and the management of Mackenzie Davidson's localising apparatus are also described. The book is written in a clear and systematic manner, and conveys a large amount of correct information in a small compass. It fills its purpose as a primer for X-ray workers, especially for work under Service conditions. We think there are better forms of mercury jet interruptor than the one chosen for description. With occasional revision to keep pace with new inventions and adaptations, this little work should be valuable for a long time to come.

Popular Fallacies. By A. S. E. Ackermann. 312 pp. 8 in. by 5½ in. Eight full-page plates. (London: Cassell and Co.) 6s.

IT is never too late to learn, and Mr. Ackermann has produced a work which we think few will look through without learning something. Although written by one who is well known in electrical engineering circles, the book is addressed to everybody, and we may almost say its subject is everything. Briefly, the writer's object has been to collect together a number of matters of a miscellaneous nature, about which misconceptions commonly exist, and point out in simple language the correct facts of each case. It should be said at once that only questions of fact are dealt with, matters of opinion do not, as a rule, come within the range, and popular beliefs in any way involving the supernatural are avoided except in a very readable appendix, in which the dividing line between ignorance and superstition is discussed. Here and there, however, as in a paragraph relating to vegetarianism, the author has allowed himself to wander on to debatable ground. The general scheme divides the book into sections according to subject-matter, but otherwise there is fascinating and often humorous incongruity in the sudden changes of theme. Dipping at random among the pages to show the wide range covered, we find the view commonly held in England that more beer is drunk per head in Germany than in the United Kingdom most effectually disproved by statistics, and a few pages later a diagram is given to dispel the popular belief that the human heart is well to the left side of the body instead of, as it really is, nearly in the centre. A brave attempt is made to teach the housewife that sunshine does not put out the fire, and in the historical section the beliefs which we have held from our childhood, that William Tell shot an apple from his son's head, and Lady Godiva rode naked through the streets of Coventry, are rudely shaken. Passing on to the fallacies connected with technical and scientific matters, subjects on which the author is well qualified to speak, there is a great deal to interest and to amuse. The technical reader will naturally find much that is obvious, but the crispness of the explanations and the evidences of the author's fine sense of humour which pervade the whole book prevent any portion becoming wearisome. We are glad to see the absurdity of the conventional zigzag representation of lightning pointed out (although this paragraph is hardly included in its right section), and due credit given to the great Turner for the accuracy of his delineation of the lightning flash. The explanation of the formation of the vitreous mass sometimes termed a thunderbolt, which, of course, is formed by the action of the discharge on the earth and does not fall from the "blue," is also misplaced in the classification. The technical Press is quoted to show that the belief that beech trees afford protection from lightning is unfounded, and the unimpeachable authority of the *Daily Mail* is brought forward to give an example of persons sheltering beneath beech trees who have been killed by lightning. This is, perhaps, a case where the subject has been dismissed too readily, for although the statement that beech trees afford protection from lightning is an exaggeration, statistical researches by Prof. A. G. McAdie, of the United States Weather Bureau, published last year, have shown that some trees are much more liable to be struck by lightning than others, although a satisfactory explanation for this has not yet been arrived at. The oak, for example, was found to be specially liable to injury, but the beech is recorded as being only infrequently affected. Before leaving the subject of thunder and lightning, it is gravely pointed out that "putting cold iron bars on barrels of beer" is of no avail to prevent "the beer being turned sour by thunder." Space does not permit of our referring to all the paragraphs upon which we should like to comment in this section, but we may express our pleasure that the deceptions (possibly of themselves and certainly of others) of the wielders of "divining rods" for finding water are exposed, and our sympathy with those who learn for the first time that Egyptian cigarettes are not made of tobacco grown in Egypt. It may appear a little ungrateful after the enjoyable half hours we have spent with this fascinating work to point out misprints, but we should like to ask Mr. Ackermann for the address of the man mentioned on page 36, who weighed only 12lb. 12oz. before lunch, and to point out that on page 10, in the title of the fallacy as to the invisibility of steam, the word invisible has been inadvertently printed instead of visible.

HEAVY ELECTRIC TRACTION IN AMERICA

THE following summary of heavy electric traction installations recently completed or in progress in America, taken from the report of a committee of the American Street and Interurban Railway Association, and published in the *Street Railway Journal* (New York), is of interest as showing the directions in which electric traction is tending in America.

CONTINUOUS CURRENT 500 TO 600-VOLT INSTALLATIONS.

New York Central & Hudson River Railroad.—This installation, which has been in progress for some years, and which comprises 35 100-ton locomotives, and 131 multiple-unit cars, has been practically completed and is in successful operation.

Detroit River Tunnel Co.—Six 100-ton locomotives.

United Railways, Portland, Ore.—One 35-ton locomotive.

Boston Elevated Railway Co.—This company, which has operated heavy elevated service for a number of years, has under construction 308 160-h.p. motors for use as double equipments.

Metropolitan West Side Railway Co., Chicago.—Two hundred and twenty-eight 160-h.p. power motors have been added to the previous equipment of this company's motor power for use with multiple-unit control as double equipments.

Philadelphia & Western Railroad.—One hundred cars, each equipped with four 125-h.p. power motors.

Brooklyn Rapid Transit Co.—This company has added to its rolling stock 100 elevated cars, each equipped with two 200-h.p. motors with multiple-unit control.

West Jersey and Seashore Railway.—Eighty cars, each equipped with two 200-h.p. motors.

Philadelphia Rapid Transit Co.—This company has added to its equipment 170 125-h.p. motors for use in two-motor equipments.

The Hudson Cos., New York.—Fifty cars, each equipped with two 170-h.p. power motors.

Buffalo, Lockport, & Rochester Railroad.—Nineteen cars, equipped with four 75-h.p. motors each.

Texas Traction Co.—Fifteen cars, each equipped with four 75-h.p. motors.

West Shore Railroad Co. (Oneida Railway Co.), Utica.—Fifteen cars, each equipped with four 75 h.p. motors.

Pittsburg, Harmony, Butler & Newcastle Railway Co.—Twelve cars, each equipped with four 75-h.p. motors. This equipment is noteworthy as contemplating the use of 1,200 volts on the trolley, two 600-volt motors being connected in series.

Buffalo & Lake Erie Traction Co., Buffalo, N.Y.—Eight cars, each equipped with four 100-h.p. motors.

SINGLE-PHASE ALTERNATING-CURRENT INSTALLATIONS.

New York, New Haven & Hartford Railway Co.—This installation, which has been in progress for the past two years, has been practically completed, and is in successful operation. It comprises 35 90-ton locomotives operating both from 11,000-volt, single-phase trolley and a 650-volt continuous current supplied from the third rail.

Spokane & Inland Railway.—This installation comprises 14 locomotives, six equipped each with four 100-h.p. motors and eight equipped each with four 75-h.p. motors; also 21 passenger cars, each equipped with four 100-h.p. motors. This road is operating partly from 6,600-volt trolley and partly from a continuous current. Length of track, 146 miles.

Sarnia Tunnel.—Five 62-ton locomotives; trolley voltage, 3,300 volts.

Illinois Traction System.—One 50-ton locomotive and eleven cars, each equipped with four 75-h.p. motors; trolley voltage, 3,300.

Erie Railroad, Northern New York.—Six cars, each equipped with four 100-h.p. motors; trolley voltage, 11,000. Length of track, 34 miles.

Washington, Baltimore & Annapolis Railway Co., Baltimore, Md.—This equipment comprises 21 cars, each equipped with four 125-h.p. motors; also four cars each equipped with two 125-h.p. motors; trolley voltage, 6,600.

Richmond & Chesapeake Bay Railway Co., Richmond, Va.—Four cars, each equipped with four 125-h.p. motors; trolley voltage, 6,600.

POLYPHASE INSTALLATIONS.

Great Northern Railroad, Cascade Tunnel, Washington.—This equipment will comprise four locomotives, each of 100 tons, to be operated on a 3,000-volt, three-phase alternating current.

CONTINUOUS CURRENT 1,200-VOLT INSTALLATIONS.

Southern Pacific Co., Oakland, Cal.—This equipment will comprise 44 cars, each to be equipped with 125-h.p. motors, to be run permanently two in series on 1,200 volts. There are also to be 40 trailer equipments.

Indianopolis and Louisville Railway.—Ten cars, each to be equipped with four 75 h.p. motors, connected two in series for 1,200-volt working.

Experiments are also being made on Pennsylvania Railroad, who are preparing to equip their new New York terminus and the tunnels connecting Manhattan Island with New Jersey and Long Island for electric traction, an experimental 140-ton, 15-cycle, single-phase, 11,000-volt locomotive has been constructed.

THE SUPPLY OF TUNGSTEN

IN view of the rapidly growing demand for the metal tungsten principally for the manufacture of filaments for incandescent lamps, and the difficulty which firms requiring large quantities of that material have in obtaining supplies, the following particulars, taken from the *Journal of the Society of Arts*, are of interest.

The market for tungsten ore is still expanding, and according to a recent bulletin of the United States Geological Survey, seems now to be almost as sure as the market for copper and other staple ores. Prices during the past year have varied from 21s. to over 50s. (depending on quality) per unit for ore containing tungsten acid.

The chief ores of commercial importance are wolframite and scheelite, the former a tungstate of iron and manganese, containing up to 76 per cent. tungstic acid, the latter tungstate of lime containing up to 80 per cent. tungstic acid. The greatest producing locality in the United States is Boulder County, Colorado, where the ore occurs as a wolframite breccia. An analysis of the crude ore from the most important deposit yet discovered in the United States near Crescent City, Colorado, gave tungstic acid 39·7 per cent., FeO 12·8 per cent., MnO 6 per cent., insoluble matter 42·3 per cent. In commercial working, it would be easy to produce a 60 to 65 per cent. tungstic acid concentrate from this deposit.

It has long been known that wolfram was associated with tin ores in Cornwall, but until recent years it has not been separated to any extent. Magnetic separation was introduced some years ago, and some measure of success in the separation has been attained in various mines. Tungsten is feebly magnetic, and requires higher magnetic power than some other ores. The magnetic separation is, however, not complete, and there is still room for considerable improvement in the treatment of Cornish ores. Some discussion has recently taken place regarding the genesis of magnetic separation in Cornwall. The credit for its introduction, according to the Cornish correspondent of a leading mining journal, is due to Professor Bauerman and Mr. W. Thomas. Moissan has shown that it is an easy matter to prepare crude tungsten in the electric furnace, and that this might be refined by remelting the metal in presence of an excess of tungstic acid.

Faraday House.—As a result of a recent examination the following awards have been made:—Bertie Travers Alston, Bedford Grammar School, an exhibition of twenty-five guineas, tenable for two years. Joseph Herbert Shannon, the Royal School, Dungannon, Ireland, an exhibition of twenty guineas, tenable for two years.

A Large Vertical Shaft Rotary Converter.—A description is given in the *Western Electrician* of a 2,000 kw. rotary converter, with a vertical shaft running at 167 r.p.m., which has been installed in one of the sub-stations in Chicago. Electrically, the characteristics of the new machine are identical with those of the older horizontal type of rotary made by the General Electric Co., the features of the vertical rotary being in economy in various points, simplicity and accessibility. Some of the points of advantage are apparent from a comparison of figures. The floor space required for a horizontal rotary of 1,000-kilowatt capacity is 11 ft. 2 in. by 11 ft. 7 in.; for the vertical machine of this size the floor space measures 9 ft. 8 in. in diameter. For the 2,000-kilowatt machines the horizontal type takes up a space measuring 16 ft. 6 in. by 16 ft. 8 in., while the space required for the vertical rotary measures 15 ft. 3 in. in diameter. In many instances clearance is an important matter, and here the vertical type of rotary shows to advantage also. The 1,000-kilowatt horizontal machine measures 9 ft. 7 in. above the floor, against 7 ft. 3½ in. for the vertical. The height above the floor of the 2,000-kilowatt machines is 12 ft. 11 in. for the horizontal and 9 ft. 3 in. for the vertical. The vertical type of rotary also shows a gain of approximately 40 per cent. in speed, and there is a saving of about 17 per cent. in weight for machines of similar capacity. The armature is supported from the top of the shaft, and revolves on oil step bearings. The shaft is 23 in. in diameter, or nearly one-half its height. Sleeve bearings on the sides of the shaft are provided for keeping the armature in alignment.

ELECTRICAL SCIENCE

British and American

Friction at Surfaces Traversed by Electric Current.—An article in the December *Physical Review*, by P. R. Heyl, describes some experiments on the effect on the friction coefficient of passing a current across the contact. The matter is of some interest in view of the fact that sliding contacts are common in practice; but in the present article the author confines his attention to the friction between iron and mercury and between carbon and mercury. The iron or the carbon was used in the form of two vertical cylindrical electrodes. Two electrodes of the same material were attached to two axial points of a heavy copper rectangle, so that they were in line, and the whole was suspended so that the electrodes dipped slightly into separate mercury cups at different levels. The suspension was a wire, which gave torsional vibrations to the rectangle and electrodes about the common axis of the electrodes. The current was led in at one mercury cup and out at the other. The electrodes were about 3 mm. in diameter, and the surface of contact in each cup was about 0·075 sq. cm. Thus with a current of 6 amperes the current density was about 80 amperes per sq. cm. at each place of friction. Greater currents than this could not be used for fear of forming an arc. The experiments consisted of finding the damping of the torsional oscillations, first, when no current was running, and then when the current was switched on. The effect of heat on the viscosity of mercury was eliminated by alternating these two sets of observations. Using iron electrodes, it was thus found that with a current density of 80 amperes per sq. cm. there is no change in friction as great as 1 per cent. For carbon, with about the same current density, there is an apparent change of about 14 per cent. But with carbon rods there was a considerable development of heat; probably the film of mercury in contact with the rod of carbon was heated rather intensely. Making allowances for this, the author concludes that practically all the difference of damping in the case of carbon electrodes is due, as in the case of iron electrodes, to the reduction of the viscosity of the mercury by warming.

Continental

Electron Theory of Dispersion.—An important advance in the explanation of optical dispersion has been made by H. Erfle, who contributes the results of an elaborate investigation to No. 14 of the *Annalen der Physik*. He used Abbe's spectrometer, and arranged it so that the beam returned upon itself. He examined benzol, methyl iodide, and alpha-monobromonaphthalene, determining from the dispersion curve the constants of Drude's dispersion formula and the number p of optically effective electrons attached to each molecule. He found that the constants deduced accounted completely for the ultra-violet and infra-red absorption bands. Another consequence of the theory is that for an infinitesimal wave-length both the deviation and the absorption of the beam become infinitesimal. Most organic compounds have more than one proper vibration in the ultra-violet. The number p of electrons per molecule is independent of the temperature, but the number affected by light increases as the wave-length of the light increases. Double linking reduces p, but does not halve it. Treble linking also reduces p, but not so much as doubling. The number p is extremely sensitive to impurities, and can, indeed, like Brühl's molecular dispersion, be used for detecting impurities.

Ionisation by Bubbling.—Lord Kelvin showed in 1894 that air bubbled through water possesses an electric charge. The charge is negative when the water is pure, but positive when the water is saline or acidulated. L. Bloch describes, in Bulletin No. 268 of the French Physical Society, some experiments in bubbling dust-free air through distilled water. He finds that though the air has a negative charge, this charge represents only the difference between negative and positive ions contained in it, both kinds being undoubtedly present. Moreover, they have a fairly high mobility of the order of 1 mm., or only ten times less the ions produced by radium or X-rays. They are therefore of quite a different order from the heavy ions found in flames and near waterfalls. The negative ions are about twice as mobile as the positive ions. All this is changed when the water is acidulated. The air is then charged positively. The ions become heavy ions. The mobilities of positive and negative ions are the same, and are of the order of $\frac{1}{10}$ mm. The concentration at which the sign of the total charge is reversed is $\frac{1}{14}$ normal in the case of sulphuric acid. Heating increases the proportion of heavy ions present, and the effect is very sensitive to changes of temperature. Alcohol shows similar effects, but not vaseline oil or mercury. It seems to be greatly a matter of surface tension.

Majorana Effect.—The magnetic double refraction of liquids discovered by Majorana requires very intense magnetic fields for its demonstration. Cotton and Mouton have shown that this effect, when observed in certain colloidal liquids, may be explained as due to the ultra-microscopic particles suspended in them. In Bulletin No. 268 of the French Physical Society the same authors report an important advance in the observation of the same effect, now for the first time found in pure liquids. They worked with the great electromagnet of the Zurich Polytechnic, which gives a field of 30,000 units over several cm. The effect was first observed in nitrobenzene, already notorious for its pronounced Kerr effect. The effect was found to be proportioned to the square of the magnetic field, and, unlike colloidal iron hydroxide, it showed no signs of saturation in the strongest fields. Benzene itself showed an effect amounting to one-fourth of that in nitrobenzene. But all the liquids of the aromatic series show it more or less. The fatty series does not show this effect, so that we have here a new criterium for distinguishing the two series. But the phenomenon is not confined to the aromatic liquids, as CS_2 shows it also. It is not due to suspended particles, but possibly to molecular aggregations invisible in the ultramicroscope.

Collective Forms of Energy.—The analysis of sound and light into periodic motions forms the foundation of optical and acoustic science. In the kinetic theory of gases, and latterly in the electron theory of electricity and magnetism, the analysis has been concerned with irregular motions treated statistically. This method is likely to become increasingly necessary and useful in physics. Some general principles concerning it are laid down by G. Helm in the *Physikalische Zeitschrift* for November 15th. If a body receives an increment of energy dE, and is thereby endowed with an intensity of energy i, then the ratio dE/i always increases from one body to another when dE is positive and is transferred from one to another. In other words, the energy loses in "intensity" by transfer, and is only transferred when it can lose in intensity. Now the sum of such quantities dE/i is strictly equivalent to what in thermodynamics is called entropy, and it also has the property of always growing when energy is transferred. This property is, therefore, not limited to heat. It applies to all "collective" forms of energy, and all irreversible phenomena are characterised by the occurrence of collective energy. Disordered motions have already been thoroughly investigated by Gibbs, but Planck's treatment of radiation shows that the method is not confined to mechanical quantities.

Japanese Exhibition, 1912.—This exhibition, which will be known as the Grand Exhibition of Japan, 1912, will be opened in Tokio on April 1st, 1912, and will be closed on October 31st. Foreign exhibits will be divided into five classes, of which one will relate to electricity. All materials for exhibition purposes will be admitted free of duty. The exhibition site will comprise about 292 acres.

Lord Kelvin's Will.—Under the will of the late Lord Kelvin, the whole of his property and means pass absolutely to Lady Kelvin, with the exception of a legacy of £5,000 to Glasgow University, which is to be applied by the Senate in promoting research and teaching physical science in connection with the chair of natural philosophy. The executors are Lady Kelvin, Dr. J. T. Bottomley, and Dr. J. F. Bottomley, nephew and grand-nephew respectively, and Lord Kelvin's solicitor, Mr. T. Warren, of Glasgow. The total amount of the will has not yet been lodged, but it is understood to be several hundred thousand pounds.

Power Developments in South Carolina.—A considerable development in electrical cotton-mill driving is taking place in South Carolina, U.S.A., where the spread of electrical driving since its introduction in 1894 has been rapid enough already to account for more than one-third of the total 300,000 h.p. used in cotton-mill driving in this region. Ther are in the neighbourhood of Charlotte, N.C., two principal water-power schemes, that of the Whitney Co. on the Yadkin river, and the Southern Power Co.'s undertaking on the Catawba river. The former scheme was originated by Mr. C. C. B. Hambley, an Englishman, and the hydraulic works started in 1904 have made considerable progress. According to a Chicago newspaper a dam 60 ft. wide and 47 ft. high has been constructed, which renders an enormous storage area available. On one side of the dam a canal 130 ft. wide and 30 ft. deep has been constructed, which carries the water about 4½ miles to the pressure pipes to the power-house, where turbines aggregating 40,000 h.p. will be installed. Two other stations in the same neighbourhood are projected, which are to produce a further 90,000 h.p. The Southern Power Co. already distribute power to a large manufacturing district from a 10,000 h.p. Catawba station and a 40,000 h.p. station known as the Great Falls plant. A further 40,000 h.p. plant is under construction at Rocky Creek, and another of 24,000 h.p. capacity at "Ninety-nine Islands," near Spartanbury, and additional power-houses aggregating some 200,000 h.p. are projected at other points on the Catawba river.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

IN the *Zeitschrift für Elektrochemie* of December 20th, Kurt Arndt publishes an article upon viscosity and conductivity. It has been shown by a number of workers that there is a more or less constant difference between viscosity of a solution or of a fused salt and electrical conductivity. That is to say, with increase in viscosity there is a decrease in the conductivity, and *vice versa*, this being due to the increased or decreased fluid friction upon the passage of the ions. Walden, who has recently worked with a normal electrolyte, tetraethyl-ammonium iodide, which he dissolved in a large variety of organic liquids, stated that the product of the equivalent conductivity and the internal friction of the fluid is a constant, which is independent of the temperature or the nature of the solvent. A practically similar conclusion was come to by Jones, Lindsay, and Carrol, working with mixtures of methyl alcohol and water. A good deal of work has also been carried out with fused electrolytes, but the agreement in this case is by no means constant. Arndt has now carried out experiments with fused salts at different temperatures. With increase of temperature the viscosity decreases, but the conductivity increases. But the product x.n, i.e., the conductivity by the viscosity is not constant. In the case mentioned a fused mixture of B_2O_3 $NaPO_3$ showed the rather remarkable result when the equivalent conductivity was reduced to the same viscosity, that the conductivity was independent of the quantity of added sodium metaphosphate. In other words, the sodium meta-phosphate is completely ionised. Another interesting point brought out is that in the fused condition sodium nitrate conducts half as well again as the potassium salt, but in aqueous solutions the conductivity is in the reverse order, the potassium salt conducting better than the sodium salt. This may be due to a film of the solution moving with the ions. If, then, the $Na^{\cdot}$ ion has a thicker film than the $K^{\cdot}$ ion, the friction will be greater, and consequently the conductivity less.

In the *German Patent* 181,656, Rudolf Schaar describes a method for obtaining either pure gases or mixtures of gases in varying proportions by electrolysis. The process consists in altering the size and position of the electrodes and of having a portion between the electrodes, which, however, does not reach to the bottom of the bath, and can be raised or lowered at will. When the solution is electrolysed with insoluble electrodes, oxygen is given off at the anode and hydrogen at the cathode. The gas causes eddy streams, and if one electrode be small and the other large, and the portion be raised to a certain position, the eddies can be caused to carry the bulk of, say, the cathode gas under the portion and up into the anode compartment, so that a mixture of the two gases is obtained. If pure hydrogen and oxygen are required, then the cathode is made double the size of the anode.

In the *Zeitschrift für Elektrochemie*, 1907, 701, H. Lee and A. Baezen compare the relative value of continuous and alternating currents for heating air or for working a resistance furnace. They have compared the yields of nitric acid with arc flames in air, using electrodes of iron, or platinum and oxide electrodes. With the same energy in each case, practically concordant results were obtained with continuous and with alternating currents. The conditions must, however, be such that the same form of arc flame is produced in every case. The authors conclude that variations of yield are not due to any difference between the continuous and alternating current, but may be caused by differences in the subsequent manner in which the reaction products are cooled. Generally speaking, a higher voltage is required with alternating currents for the same energy consumption than for continuous currents; this may, perhaps, be due to the cooling of the electrodes between the alternations. The most important influence in obtaining high yields is the condition of the arc flame, and also upon the way in which the products are removed from the sphere of action. For the production of calcium carbide and for heating crucibles, both continuous and alternating currents required practically the same voltage and the same current.

The British Aluminium Co. have more than realised their anticipation of being able to commence manufacturing aluminium at Kinlochleven in the beginning of the New Year, as work was commenced on Christmas Day, and the machinery was in full operation by the end of the week. The temporary factory now being operated is situated between the new village and the great dam. A special dam has been constructed for operating the present plant, and turbines capable of developing 3,000 electrical h.p. have been installed. The principal works are being actively pushed forward, but some time will elapse before they are completed.

ELECTRIC LIGHTING PROVISIONAL ORDERS

WE give below a complete list of applications for Provisional Orders deposited with the Board of Trade, under the provisions of the Electric Lighting Acts, 1882 to 1890, for the Session of 1908. In cases where the name of the promoter is not given, the local authority has lodged the application :—

Barrhead, Strathclyde Electricity Supply Co., Ltd.; Barton-upon-Irwell; Bath (Rural) (Amendment); Bispham-with-Norbreck; Bridgend (Extension); Caldy Manor, Caldy Manor Estate, Ltd.; Carmarthen, Messrs. J. B. Saunders & Co.; Clydebank (Amendment), Clyde Valley Electrical Power Co.; Dundee (Extension), Dundee Gas Commissioners; Fleetwood; Fleetwood, Broadstone, Ltd.; Halesowen (Rural), George Balfour; Hendon (Amendment), Messrs. Crompton & Co., Ltd.; Heswall (Rural); Johnstone, Strathclyde Electricity Supply Co., Ltd.; Llandaff and Dinas Powis (Rural), (Amendment); Llansamlet, Rural District Council of Swansea; Lowestoft (Oulton Broad Extension); Lymington (Extension), Lymington Electric Light and Power Co., Ltd.; Macclesfield (Amendment); Oulton Broad; Portsmouth; Rutherglen (Amendment); Southampton; Sowerby Bridge; Tewkesbury; Woking, Woking Electric Supply Co., Ltd.

CATALOGUES AND PAMPHLETS RECEIVED

ELECTRIC LIGHTING PLANT AND ACCESSORIES.—The large bound catalogue of some 300 pages, issued by Messrs. Drake & Gorham, forms a useful work of reference for those laying out electric light installations, and deals in some detail with boilers, producer gas plant, steam, gas, and oil engines, turbines and engine-room stores, shafting, pulleys, and belting, dynamos, motors, switchgear, measuring instruments and accessories, storage batteries, wires, cables, &c., for lighting, power, telephones and bells, and lightning conductors. Incandescent lamps of the carbon filament, tantalum, and Nernst types, arc lamps, switches, wall plugs, lamp-holders, steel tubing, casing, &c. Electric bells, telephones, heating appliances, and fans. Various types of machinery and appliances for domestic, dairy, and farming purposes, and motor-cars and accessories.

INTERCOMMUNICATION TELEPHONES.—A leaflet from the Sterling Telephone & Electric Co. gives particulars of several patterns of intercommunication telephone of the wall and table types. An automatic replacement instrument is tested with only a single lever, and calls may be made irrespective of its position, in addition to the "Era" multiple lever type, of which very large numbers are in use. In all the single-lever instruments the contacts are enclosed in the instrument case.

POCKET-BOOKS, DIARIES, ETC., FOR 1908

The General Electric Co. have presented some of their friends with an exceptionally fine and well-made blotting-book with flexible leather cover, fitted with capacious pockets.

This year's wall calendar of the D.P. Battery Co. fully maintains the high artistic standard set by its predecessors. The principal feature is a coloured view of part of the company's works in Derbyshire, showing the large water wheels and chimney shafts of the auxiliary steam plant by which the works is driven.

We have received from the Electric Construction Co. a neatly made pocket-case with memorandum pad and transparent window for season tickets, &c., and a pair of light and convenient penholders.

Messrs. Johnson & Phillips have sent us a miniature calendar and diary for 1908, neatly bound in crocodile skin.

Messrs. Siemens Brothers & Co., Ltd., conjointly with Messrs. Siemens Brothers Dynamo Works, Ltd., are distributing this year to their friends a somewhat enlarged edition of their well-known diary, which contains a number of useful tables, &c., and some interesting illustrations showing the wide range covered by the activities of the group of Siemens companies.

A neat waistcoat pocket diary and notebook for 1908, bound in Russia leather, is being issued by the Brush Electrical Engineering Co.

A very artistic wall calendar is being distributed by Messrs. T. W. Broadbent, of Huddersfield, to their friends, which contains a three-colour reproduction of a painting entitled "Harvesting in Hertfordshire," by Alfred Elias.

An ingeniously arranged calendar in the shape of a large incandescent lamp with revolving discs for the days of the week, month, &c., has been issued by the Pope Electric Lamp Co.

Telegraph Traffic.—The past week has been fairly free from derangements of telegraphic communication, the only cable which has given out being the one between Bathurst and Bissao, on Christmas Day. The *via* Fao route was again interrupted between Bagdad and Bassorah on the 26th ult., and some inconvenience was caused by interruptions to landlines, owing to the recent storms.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 27th

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1906 Patents

19,737, BRITISH THOMSON-HOUSTON. This specification relates to improvements in signalling on electric railway systems, and utilises a power-house dynamo having one of its poles connected directly to an insulated conductor or feeder extending over the route; the other pole is connected to both track rails, which are bonded together, and a series of sectional track-controlling conductors, or rails parallel to them, with semaphores or signals controlled in their operation in one direction by the use of rotary electric motors, and in the reverse direction by the application of a constantly acting force, such as gravity or a spring, the arrangement being such that the signals are held locked at safety against the influence of the constantly acting force, and with the source of electrical energy normally disconnected therefrom. It also combines a system of such signals with sectional third rails, local sources of electrical energy therefor, and switching devices connected in circuit with the sectional track-controlling conductors or rails in such a manner that when any sectional third rail is made alive the corresponding signal or signals are displayed at danger or caution through the agency of the constantly-acting force. Three claims, two figures.

26,212A, COWPER-COLES. Improvements in anodes for electric deposition. It is proposed in this specification to provide an improved means for causing the anode to gradually move towards the cathode surfaces, as the former is gradually dissolved away, by means of screw threaded rods carrying the anodes in section, and each working in a nut, and cams adapted to be turned through the medium of bevel gear, so as to bear against the back of the anode sections. Two claims, two figures.

28,112. BRITISH THOMSON-HOUSTON & WOODBRIDGE. This specification relates to improvements in switch-controlling mechanism for electrical installations, and consists of an arrangement of interlocked levers and switches capable of home and remote control, whereby a switch can be opened or closed by hand-operated means near the switch, or from a distance. The line switch mechanism also controls the opening and closing of an earthing switch, so that the latter may not be closed except when the line switch is open, or *vice versa*. Four claims, three figures.

1907 Patents

880. J. C. LINCOLN. The object of this invention is to construct electric motors so as to secure an unusual range in the speed variation, whilst avoiding harmful sparking at the brushes of the motor, particularly at high speeds, and also to adapt the motor for working equally well in either direction of the armature. The motor consists of the usual field structure, within which the motor is designed to rotate. In connection with the armature are means for withdrawing it laterally from the field structure. The chief feature is the means for affording a commutating field during the high-speed positions of adjustment for the armature, which consists of an electro-magnet laterally positioned beyond the field structure of the motor adjacent to the armature when withdrawn therefrom to the high-speed position. This electro-magnet is connected in series with the armature of the motor. Three claims, six figures.

2,759, PAGE, AND THE U.S.A. LIGHTING & HEATING CO. This specification relates to an improved system for transmitting power to dynamo electric machines suspended from trucks. The object of the invention is to prevent the wear upon the axle of the dynamo and the consequent destruction of the armature which occurs with the usual power transmitting mechanism. The driving pulley is mounted on the frame of the dynamo, the armature shaft being connected to the pulley by a lost motion connection, such as a "dog" or "spider," which is loosely connected to the pulley. There may be relative movement between the driving pulley and the armature shaft, and all the transverse strains due to the movements of the dynamo and the pull of the belting are thrown on the field frame of the dynamo instead of on the armature shaft. The axle is provided with a suitable driving pulley, connected to a belt with a pulley connected to drive the shaft of the dynamo. Suitable belt-tightening springs are provided, and downwardly depending rods are secured to the outer ends of the beams, the lower ends of these rods being connected by cross rods. The field of the dynamo is provided with downwardly depending lugs or ears, to which is secured a cross rod provided with apertures at its ends for the hooked rods. A cross rod connects the two pivot bars, and suitable bearings are provided on the frame of the dynamo. Two claims, three figures.

18,923, WESTINGHOUSE METAL FILAMENT LAMP CO. Method of fixing metallic filaments of incandescent lamps. The patent is published in full on page 12.

Specifications Published To-day

The following Patent Specifications will be published to-morrow, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

13,126A, COWPER-COLES. Manufacture of metal articles by electro-deposition.

25,050, DAIMLER-MOTOREN GES. Transmission gear for motor-driven vehicles.

28,319, STRECKER-AUFERMANN. Process for preparing printing plates by means of electrolytic etching.

28,739, BABB, CHAPMAN, & COCKSHOTT. Methods or means of electric braking.

28,775, DEUTSCHE GASGLÜHLICHT AKT.-GES. (*Auerges.*). Method of and means or apparatus for producing metallic incandescence bodies for electric glow lamps.

28,846, CROSSLEY & JACKSON. Electric ignition for internal-combustion engines.

28,897A, COWPER-COLES. Electro-deposition of iron.

1907 Patents

316, RHODES & RHODES MOTORS, LTD. Commutators for dynamo-electric machines.

1,358, AMBLER. Electric switches.

1,945. CUNYNGHAME & HOPE-JONES. Gravity escapements and electric clocks.

2,227, SIEMENS BROTHERS DYNAMO WORKS & PALAIRET. Overload electric circuit breakers and the like.

3,724, LORING. Electrical generators for flour-bleaching and subsidiary purposes.

4,172, WUILLOT & FERON. Electrical distribution systems with the aid of storage batteries.

6,280. KITSEE. Electric telegraphy.

6,849, GROSE. Electric fuse boxes and fuse holders therefor.

8,838, RUHL. Electro-mechanical toys.

9,176, LAND-UND SEEKABELWERKE AKT.-GES. Safety electric cable.

9,833. TURNER. Telephone systems and apparatus therefor.

11,123. HUNGERFORD. Electric conductors.

13,074, ALLGEMEINE ELEKTRICITÄTS GES. End pivots for the spindles of electric meters.

16,514, MACGAHAN. Synchronising apparatus for dynamo-electric machines.

18,463, FORD & WASSAM. Combined cross-ties and rail-fastenings.

18,498, BÖHM. Operative system electric locomotives.

18,793, VON KANDO. Double wire overhead electric trolly systems.

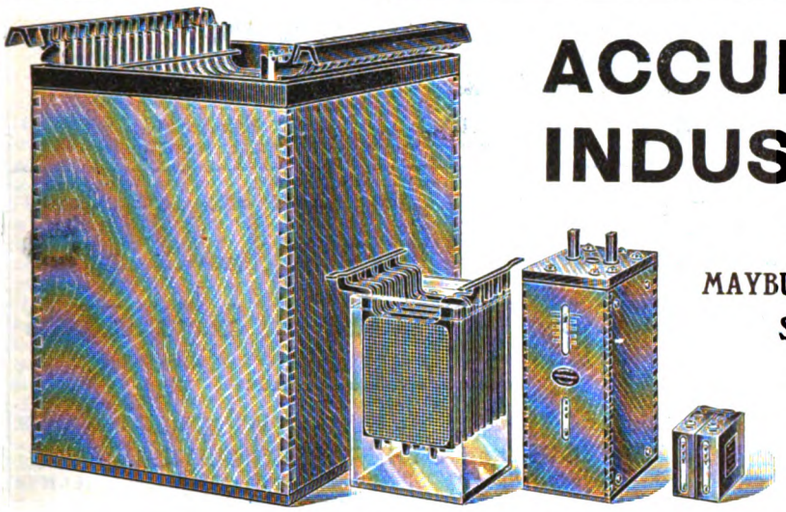
22,404, ALLGEMEINE ELEKTRICITÄTS GES. Dynamo-electric machines.

25,722, WESTINGHOUSE. Yielding resistance devices.

The following complete Specifications are open to Public Inspection at the Patent Office, but are not yet published for sale.

1907 Patents

21,535, MAICHE. Electric transformers.



26,607, FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. Direct current electrical machinery.

26,846, ALLGEMEINE ELEKTRICITÄTS-GES. Arc-lamps.

27,073. SIEMENS-SCHUCKERT WERKE GES. Electrical systems or arrangements for driving machinery subject to variable loads.

WESTON ELECTRICAL INSTRUMENT CO.

Digitized by Google

LOCAL NOTES

ACCRINGTON: *Electric Tramways.*—The new section of the tramways as far as St. John's Church, Baxenden, was formally opened for public traffic last week end. The rest of the lines to the boundaries are now practically completed.

ACTON: *Electrical Exhibition.*—It has been decided by the Acton Council to hold an exhibition of electrical goods in the Public Baths from January 18th to 25th. £82 has already been guaranteed by the stallholders, and it is estimated that the receipts will be £152.

BELFAST: *Tramway Receipts.*—In spite of the rough weather during Christmas, the receipts from the Belfast Corporation electric tramway traffic show a decided increase over last year. The figures last year were: Christmas Eve, £719; Christmas Day, £591; Boxing Day, £488; day after Boxing day, £488; total, £2,246. This year the receipts were: Christmas Eve, £782; Christmas Day, £559; Boxing Day, £594; day following Boxing Day, £531; total, £2,466, showing an increase of £220 for 1907 over 1906.

BISPHAM: *Electric Lighting Order.*—The Parliamentary agent of the Council has reported that all the preliminary stages, with regard to the Council's application for an electric lighting order are now completed.

BRADFORD: *The Church Bank Accident.*—The Bradford tramways accident on Church Bank, the steepest gradient in the city, some months ago, has led to prolonged negotiations with injured passengers. These are now completed, and it is officially announced that all claims have been settled for £2,000, plus doctors' bills. Fourteen persons were injured, and though the Corporation has always held that it was not legally liable, as the car ran away owing to pure accident, liability has not been evaded. The cost of the accident is equivalent to the gross takings on the whole system for half a week.

CASTLEFORD: *The Normanton, Castleford, and Pontefract Tramways.*—Mr. England, the tramways manager, reports as follows:—"The tramways were opened for public traffic on October 29th, 1906, and comprise 7·112 miles of track, and 10·22 miles of line reckoned as single track. At the depôt in Castleford, where the power-station and repair-shops are also situate, there are 16 cars in stock, seven of which are used on the ordinary week-day service, and all of them each week-end. During the year under review it is estimated that approximately 2,500,000 passengers have been carried. Since November 4th last cars have not run into Pontefract, owing to the Board of Trade having refused to grant a certificate authorising the running through Front Street until the required clearance of 15 inches at one particular point is obtained. At the time of writing there seems no prospect of a settlement being arrived at, as the Corporation of Pontefract will not agree to a slight narrowing of the footpath to enable the company to get the clearance. There is no likelihood of any extension to Featherstone or Knottingley being carried out for some time to come.

DUNDEE: *Electricity Developments.*—The Dundee Electric Lighting Committee made a tour of inspection, with a view of finding suitable sites for two sub-stations, which will be situated one at Lochee, and the other in the Maryfield district. Concerning the former it has been decided that ground belonging to the Tramways Department, adjoining the car sheds, shall be utilised, and at Maryfield ground between Dura Street, and Clepington has been chosen.

Electric Lighting Order.—A special meeting of Dundee Town Council was held on Friday last, when the Town Clerk reported that when the late Provisional Order for the extension of the burgh boundaries was promoted, it contained clauses referring to electric lighting, but as the Secretary for Scotland had no power to deal with that question, the clauses had to be deleted. Mr. Don, convener of the Electricity Committee, moved that steps be taken to obtain an Order from the Board of Trade to extend the area for the supply of electricity to make it co-extensive with the new burgh boundaries. This was agreed to.

EALING: *Noisy Tramcars.*—A conference has been held at Ealing by several of the councils through whose districts the London United Co.'s tramways run, and it was decided that the matter could only be dealt with by the Councils individually, and that the Councils follow the course adopted by the Acton Council, that the Middlesex County Council put in force the Act of Parliament which provides that where the tramway company did not do work which was necessary, the authority could give the company seven days' notice, and then do the work itself, and charge the cost to the company. Several members of the conference are approaching Mr. Lloyd George to see what could be done through the Board of Trade in the matter.

FINCHLEY: *Extension of Tramways.*—Negotiations are proceeding between the District Council and the County Council with regard to the proposed tramways in Regent's Park Road, Ballards Lane, and Woodhouse Lane. A number of points have been settled, but six objections raised by the local authority have not yet been satisfactorily met by the County Council.

GLASGOW: *Tramway Extensions.*—The Tramways Committee of Glasgow Corporation have had under consideration a report by Mr. James Dalrymple, the manager of the Tramways Department, regarding the proposal to carry out the powers contained in the Glasgow Coporation (Tramways Consolidation) Order, 1905, to make tramways from Great Western Road to Gairbraid Street—7 furlongs, 26 yards; and from Gairbraid Street to Possil Park—1 mile, 1 furlong, 177 yards. The total length of these sections measures 2 miles, 203 yards, and it would be necessary to double the present single line in two places, which would measure 5 furlongs, 169 yards, making the total length nearly three miles, the cost of equipping which would be £43,000. A census was taken on ten days between September 24th and October 4th, and showed that some 800 people used the route each way every day. An estimate for this route for receipts per car mile would be 5d., and taking the expenses at 9¾d.—last year's figures—there was a loss of 6¾d. on every car mile run. If a five minutes' service were given, the annual car mileage would amount to 481,593, which at 6¾d. per mile would mean a total loss of £15,600 per annum. The Committee decided not to proceed with the work of construction at present.

HALESOWEN: *Light Railways Order.*—The Light Railways Commissioners have submitted to the Board of Trade for confirmation an order made by them transferring to a company the powers conferred on the Rural District Council of Halesowen by the Halesowen Light Railway Order of 1901, and the Extensions Order of 1902, and amending those orders.

HALIFAX: *Telephone Charges.*—The Halifax Corporation Telephone (Wayleaves) Committee have resolved to recommend the Town Council to accept the undermentioned terms:—5s. per annum to be paid by the company to the Corporation for each subscriber through the local exchange up to and including 1,000 subscribers; 2s. 6d. per annum for each subscriber beyond 1,000; 2s. 6d. per annum to be paid by the company to the Corporation for each pole and bracket; a rebate of 20 per cent. per annum to be allowed by the company off the tariff rates for telephones supplied to the Corporation. The new arrangement to commence on January 1st, 1908. Except as varied by the foregoing suggestions, the existing agreement will continue in force.

HANWELL: *Electric Lighting Order.*—At the last meeting of the District Council a letter was read from the Board of Trade stating that unless the Council could show that it intended to take action in regard to the Electric Lighting Order in the course of the next twelve months, the Order would have to be revoked. At the same meeting the General Purposes Committee reported as to the terms upon which the Metropolitan Electric Supply Co. were willing to take over the Council's Lighting Order. The company desired (1) modification of the list of streets in which mains are to be laid, and to this the committee saw no objection; (2), the Council to take the supply of electricity for the offices of the Free Library at 4d. per unit; (3), the company to fix on seventy of the existing lamp-posts in certain streets new lanterns, each containing 250 c.p. Osram, or other high efficiency lamps, to renew these lamps when necessary, and supply them with energy for 3,640 hours pere annum for an inclusive payment by the Council of £4 per post per annum; (4), the company to erect twelve flame arc lamps in the Uxbridge Road, and ten in Boston Road, with the necessary standards, to carbon and clean, renew the globes, repaint the standards, and supply energy for 3,640 hours per annum, for an inclusive payment of £21 per lamp per annum, this price being subject to revision at the end of ten years: (5), the company to repay to the Council the sum of £550 expended by the latter in obtaining the Provisional Order; (6), the Council to have the right of re-acquiring the undertaking in 42 years. The committee pointed out that the company made no condition in their first offer as to street lighting. The committee could not agree to the terms now proposed, and recommended that the agreement should be on the lines of that originally proposed, with the proviso that the Council would be willing to consider the question of street lighting when the supply of electricity was available. The report of the committee was adopted, and the surveyor was instructed to obtain details of the present cost of public lighting.

HASLINGDEN: *Electricity Scheme.*—An animated controversy is proceeding in the Haslingden district, and the part taken by the Lancashire Electric Power Co. is being adversely criticised. On the one side it is claimed that Accrington could have provided for Haslingden in their recent Bill, but for the action taken by the company. However, the borough will now take up the undertaking itself, and the Corporation has decided to electrify the present steam tramway system within the borough, which falls into their hands at the commencement of the New Year. The work is being carried out by the Corporation under the Borough Engineer Mr. J. Singleton Green. Messrs. Handcock & Dykes, 1 Victoria Street, Westminster, S.W., being retained as advising engineers.

Digitized by Google

HORBURY: *Electric Lighting Order.*—The Board of Trade give notice that they have revoked the Horbury Electric Lighting Order of 1905, as to the whole area of supply, from the 19th of December, 1907, and the revocation takes place from that date.

HUDDERSFIELD: *Electricity Accounts.*—Orders for additional plant at the generating station have been given. During November the number of consumers was 2,611, against 2,584 in October, and the lamps connected, 192,169, as against 190,174. In reference to the extensions to Linthwaite and Golcar of electrical energy, the approval of the Board of Trade has been received.

KIRKALDY: *New Tramway Arrangement.*—At a meeting of the Tramway Committee of Kirkcaldy Town Council a report was submitted by Mr. Francis, Burgh Electrical Engineer, on the running of the tramway cars during the past four weeks under the system for the joint running of the Kirkcaldy and Wemyss cars, as suggested by the arbiter. He points out that, as compared with the same period of last year, the cars have run 5,016 less car miles, and have taken £26 14s. 4½d. more in receipts, while they have also carried 4,254 more passengers, so that there has been a net gain for the period mentioned of £120, which is at the rate of £1,560 per annum. From these figures it was apparent that the new system was giving greater convenience to the travelling public than the old system, since they were carrying a larger number of passengers. He recommended the Committee to give the present system a trial during all the various seasons of the year. There was no doubt that if the present receipts were maintained throughout the year the Kirkcaldy tramway and electric lighting undertakings would both be paying concerns.

LIVERPOOL: *An Improved Sanding Device.*—The sanding device described in ELECTRICAL ENGINEERING, Vol. I., p. 585, has been fitted to about 300 cars of the Liverpool Corporation. A test of the apparatus was recently demonstrated in Prescot Street, which is one of the steepest gradients in the city. The car was driven to the top, and then allowed to run back, but the sanding device so facilitated the work of pulling up, that the car was brought to a standstill in an extremely short distance. The same result was obtained when the car was driven down the hill at a speed of about eighteen miles per hour.

LONDON: *Hammersmith Electricity for Franco-British Exhibition.*—The Board of Trade have approved of the Hammersmith Borough Council supplying the Franco-British Exhibition with electrical energy, subject to the regulations for securing the safety of the public, and for ensuring a proper and sufficient supply of energy, and to the Board's regulations with respect to supply at extra high pressure. The terms between the Council and the Franco-British Exhibition Co. are as follows. The period within which the guaranteed minimum payment of £10,000 has to be made is from May 1st to October, 1908. The Council guarantees to supply 100 kilowatts on January 1st, 1908, and make a progressive increase in supply from that date up to 500 kw. to May 1st as the work advanced.

Marylebone: The Electric Lighting Accounts.—In reply to the criticisms on the local electricity undertaking, the chairman states, that instead of having only £8,000 at the end of the working year, ending March 31st, 1908, with which to meet £100,000 interest and sinking fund, as alleged in some of the criticisms, at the end of December 31st, 1907, £67,792 will have been paid on this account. There will be an estimated profit, after paying interest and sinking fund charges, of £11,000 at the end of the working year, but if there is any reduction in price per unit this will not be fully realised. The overdraft at the banker's is estimated to be at the end of December 31st £58,048, against which there is due from consumers £44,000. Expenditure on capital account is set down approximately at £1,991,500. Loans received total £1,974,920. An estimated increase of the sales for the year of 7·5 has actually been increased to 7·9.

MAIDSTONE: *Electricity Works Extensions.*—Considerable extensions have been made at Maidstone to the boiler-house and generating plant, and a complete installation of mechanical stokers has been put in, with new water purifiers. A new steam-dynamo set of 500 kw. capacity has been installed, the engine being a 940 i.h.p. Belliss & Morcom high speed triple-expansion, and the dynamo by Dick, Kerr & Co., and a new switchboard by Drake & Gorham.

NEWPORT: *Electricity Loan Granted.*—At a meeting of the Newport Electricity and Tramways Committee on Tuesday, it was reported, in regard to the conditional refusal on the part of the Local Government Board of sanction to borrow £30,000, applied for fifteen months ago, that the Board had now issued sanction for the greater portion of the loan, withholding for the present sanction for sums of between £4,000 and £5,000 upon expenditure, concerning which more information is required. The Town Clerk will furnish this, and it is anticipated that the full loan will then be agreed to, though the adverse balance of £2,600 brought forward on the revenue account must be paid off, and not further brought up from year to year.

OXFORD: *The Dolter System Tramways.*—A report has been submitted by Mr. Sellon, and adopted by the General Purposes Committee of the Oxford Corporation, to the effect that the Dolter system had not yet been working satisfactorily in any town in Great Britain for six months. According to the agreement which the Council entered into with the Dolter Co., an inspection was to be made by the Corporation of some tramway run on the Dolter system for six months, and a definite answer as to whether they considered it satisfactory for Oxford, was to be given to-day. With this object in view the Corporation were invited by the company to visit Hastings last week. After luncheon at the Queen's Hotel an inspection was made of the whole of the line laid upon the Dolter system, extending to the western end of St. Leonards along the sea front for about 1¾ miles. The greater part of this is double line. The party rode on the cars to the further end of the line, and then dismounted and walked back along the track from end to end. After dark the party again walked along the line, in order the better to observe the flashing of the studs, and the alleged interference with the lights in the cars, about which so much has been said. Since the track was first laid in Hastings many improvements have been effected. The studs, which at first were raised above the level of the track to an average extent of about five-eighths of an inch, have now been considerably worn down to about a quarter of an inch. When the cars first started to run a horse received a shock from a live stud, but since that time no accidents have occurred. The fact that the Board of Trade now considers the system quite satisfactory is revealed by the fact that a full licence has been granted. At the first application a licence for six months was granted, and on the second occasion another licence for a similar period was allowed. The conditions of this line are very different from those prevailing at Oxford. The sea front is a wide thoroughfare, on which the track is laid at one side, whilst considerable space is left on the other for vehicular traffic. For this reason it is comparatively seldom that the tram track is used by the ordinary traffic. Only perhaps about three hundred yards traverse a business street, and that is fairly wide. The conditions at Torquay more nearly approach those at Oxford, so that it is quite possible that the Corporation may still decide to visit Torquay also.

PONTYPRIDD: *Rhondda Tramway Route.*—Colonel Druitt, of the Board of Trade, conducted an inspection on Friday last of the new viaduct at Pontypridd, connecting the tramways of that town with the Rhondda Valley. The inspector expressed himself satisfied with the structural arrangements, and the electric tramcars of the District Council commenced running on Saturday last.

SPALDING: *Urban Council Surcharged.*—The district auditor (Mr. J. A. Cole) has surcharged members of the Spalding Urban Council with £66, being amount incurred in opposing an electric lighting scheme, powers for which were being applied for by an outside company. The ground of the surcharge is that the Local Government Board were not notified of the action the Council were taking in the matter. The Council are appealing to the Local Government Board against the decision.

TORQUAY: *Tramway Progress.*—At Torquay the demand of the Tramways Company for current has increased so considerably that extensions will have to be carried out at the electricity station, which is now taxed to the utmost capacity.

WIGAN: *Electricity in Collieries.*—We learn officially that Messrs. Pearson & Knowles, Coal and Iron Co., Ltd., one of the largest concerns of the kind in the country, are having powerful electrical plant put down for haulage, driving, and other purposes at their extensive collieries at Abram, near Wigan.

Electric Lighting Order.—The Board of Trade give notice that they have revoked the Wigan Rural District Electric Lighting Order, 1903, as to the whole area of supply, from the 30th of November last, and the revocation takes effect from that date.

WIMBLEDON: *Electric Lighting Extensions.*—The Electrical Engineer reports that the actual cost of erecting 33 flame arc lamps in Worple Road, Kingston Road, and Haydon's Road, was £639. The Electric Lighting Committee have decided in favour of a sum of £639 8s. 10d., in addition to the £1,500 already voted in relief of rates, being transferred from the electric lighting account to the general district fund. The Electrical Engineer has submitted a report upon the relative cost and efficiency of tantalum lamps, osram, and carbon filament lamps, now in use, for street lighting purposes, and acting upon the report, the Electric Lighting Committee has decided that no extensive alteration should be made at present in the existing system, but that one 32 c.p. carbon filament lamp be gradually substituted in the street lamps for each pair of 16 c.p. lamps now used. Complaints of defective lighting having been received, eight of the carbon filament lamps in Kingston Road are to be replaced by osram lamps, and a 32 c.p. carbon filament lamp substituted for each pair of 16 c.p. lamps in Quicks Road, and Barghley Road. An additional lamp-post, fitted with

Digitized by Google

a 32 c.p. carbon filament lamp, is to be placed in Stanton Road. Failures of the electric supply occurred in the district during December, caused, on one occasion, by the breakdown of a 75 kw. transformer, and on another by a pick being driven into a supply cable. Two 100 kw. transformers were hired for £10 and 10s. each per day when used, in view of the breakdown mentioned above.

WINNIPEG: *Electric Progress.*—It is estimated by experts that by their completion of the water-power plant the Winnipeg Electric Co. will save quite $100,000 a year in working costs, which would in all probability equalise any reduction in traffic in Winnipeg that may result from any easing off in business at that centre of Western activities. It is asserted that the company has 22,000 h.p. available, 15,000 of which are sufficient to satisfy its own requirement, while the balance can be disposed of to local users. Rapid progress is being made with the extension of the suburban lines, and the electrification of the section from Winnipeg to Selkirk, some 22 miles in length, at present being operated by steam, is being proceeded with. The financial position of the company has made rapid progress during the last year or two, and the stock at about 120 is regarded as an attractive investment.

TENDERS INVITED AND PROSPECTIVE BUSINESS

AUSTRALIA.—In reference to the notice on page 953 of our issue for December 19th, Mr. J. Cresswell, the Board of Trade correspondent at Adelaide, has forwarded a copy of the specification and conditions relating to the supply and delivery to the Municipal Tramways Trust, Adelaide, of special work, points and crossings for tramways. Sealed tenders, endorsed "Tender for Special Work," must reach the Chairman, Municipal Tramways Trust, 8 King William Street, Adelaide, by noon on February 11th, 1908. Tenders must be accompanied by a preliminary deposit equal to one per cent. of the total amount of the tender. The specification and conditions may be examined by British manufacturers at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, E.C.

The Victorian Postmaster-General's department invites tenders by May 26th, 1908, for the supply of one common battery switchboard of thirty sections, complete with frames, racks, power plant, and parts; also for 3,000 telephone wall sets; 1,000 telephone table sets; 150 extension switches, complete; 10 switchboards, for 2 and 6 lines; 50 switchboards, for 5 and 10 lines; 10 switchboards, for 6 and 20 lines; 10 switchboards, for 8 and 50 lines; 200 telephone wall sets, for party lines; and 100 telephone wall sets, for party lines.

BARNES.—The Council invite tenders for the delivery and erection at the Council's depôt, High Street, Mortlake, London, S.W., of a two-ton electric locomotive crane. Full particulars from the Engineer's and Surveyor's office, High Street, Mortlake, to whom tenders should be sent by January 15th.

BULGARIA.—A British Consular report states that besides Government requirements, there are various municipal enterprises in Bulgaria in which British contractors and manufacturers should obtain a share, including electric lighting and traction.

BUENOS AYRES.—The *Review of the River Plate* states that the Buenos Ayres Municipality are calling for tenders for a period of six months—May 1st, 1908—for the construction of two tube railways, and also for the renting and working of same when built. Full particulars can be obtained in the Argentine Legation in the following cities:—London, Paris, Berlin, Brussels, Rome, and New York.

CANADA.—*The Financier* states that from Montreal comes the report that a syndicate of British capitalists is prepared to spend £2,000,000 in Canada's electrical development. The scope of the enterprise will, according to Mr. Rodolphe Forget, M.P., who has been an active promoter of the scheme, include the improvement of existing electric railways, the construction of others—especially in the rural districts of Quebec Province—and the development of water powers for industrial purposes in Ontario and Quebec. One of the engineers employed by the syndicate has been in Canada for two months making a careful inspection, and one of the leading members of the syndicate is now on his way to Canada.

FINCHLEY.—Tenders are invited for the supply and erection of a 350 kw. high speed engine and dynamo combined, together with spare parts. Particulars from the Electrical Engineer (Mr. E. Calvert), Electricity Works, Squire's Lane, Finchley, N. (fee £2 2s., returnable); and tenders to the Town Clerk by January 20th.

GLASGOW.—The Corporation invite tenders for the supply of a 4,000 kw. turbo-alternator running at 750 r.p.m. Copies of the specification and form of tender may be obtained on application to Mr. W. W. Lackie, engineer, 75, Waterloo Street, Glasgow (fee two guineas, returnable), and tenders to the Town Clerk by January 14th. (See advertisement this week.)

GUISBOROUGH.—The question of electric lighting is under consideration by the Town Council, and a special meeting is to be held.

ILFORD.—The Council are to erect larger tantalum lamps down Ilford Lane from the termination of the arc lights to Loxford Bridge. Extensions of arc lighting are also to be considered shortly.

INDIA.—Tenders are invited by the Bengal and North-Western Railway Co. for 15,000 incandescent lamps. Specifications may be obtained at the company's London offices, price 10s. (not returnable), and tenders should be addressed to the Managing Director, 237 Gresham House, Old Broad Street, E.C.

KILKENNY.—The Joint Committee of Management of the Kilkenny and District Lunatic Asylum invite tenders for (1) suction gas plant, gas engines, and generators; (2) accumulators, switchboard, mains, &c. Plans may be inspected by appointment at the Asylum or at the office of the consulting engineer, Mr. L. J. Lawless, 27 Castlewood Avenue, Rathmines, Dublin, from whom copies of the general conditions, &c. may be obtained (fee, three guineas, returnable). Tenders to the Resident Medical Superintendent by January 18th.

LONDON: *London County Council.*—Tenders are invited for the supply and delivery of about 500 tons of steel slot rails and about 190 tons of conductor rails, required for the reconstruction on the underground conduit system of electric traction of certain sections of the Council's tramways. The rails must be of British manufacture. Full particulars, forms of tenders, &c., from the Chief Engineer to the Council, Mr. Maurice Fitzmaurice (fee £2, returnable), and tenders to the Clerk to the Council by January 21st.

Fulham.—The Board of Guardians has instructed the engineer to revise the telephone system at the infirmary at an estimated cost of £70 6s.

Poplar.—The Guardians invite tenders by January 8th for electrical supplies, among other stores. Tenders to the Clerk to the Guardians, 45 Upper North Street, Poplar.

Stepney.—A loan of £20,000 is being taken up from the London County Council in connection with the electricity undertaking upon the terms that such amount is taken up at once and repaid by equal annual instalments as to the sum of £10,000 within the last thirty-nine years of a term of forty-two years, and as to the sum of £10,000 within a period of thirty years, at 4 per cent. per annum.

METROPOLITAN ASYLUMS BOARD.—The Metropolitan Asylums Board invite Tenders for installation of electric lighting, &c., in the motor workshops and yard at the Mead Ambulance Station, Carnwathe Road, Fulham, S.W., in accordance with drawing and specification prepared by Mr. W. T. Hatch, M.Inst.C.E., M.I.Mech.E., Engineer-in-Chief. The drawings, conditions of contract, &c., may be inspected at the office of the Board, Embankment, London, E.C., where they can be obtained upon the payment of a deposit of £2 (returnable). Tenders to the Clerk by January 8th, 1908.

OSSETT.—An application is to be made by the Council to the Local Government Board for sanction to a loan of £23,000 in connection with the Dewsbury and Ossett tramways.

ROTHERHAM.—The Corporation invite tenders for the supply of tramway rails, fish-plates, tie-bars, bolts and nuts, and special trackwork, to be delivered in Rotherham. Specifications, &c. (fee one guinea, returnable), from the Borough Engineer, and tenders to the Town Clerk by January 17th.

RUSSIA.—The St. Petersburg Municipality have passed a resolution granting to the Tramway Committee a sum of 2,067,000 roubles (about £296,000) for the purchase of 57 new motor-cars and 210 trailer cars for the municipal tramways.

SHERINGHAM.—The Urban District Council have instructed their surveyor to report upon the cost of an electric lighting scheme.

TASMANIA.—The Town Council of Zeeham propose to borrow £3,000 for the purpose of additions to the generating plant at the electric power station.

WILLESDEN.—Application is to be made to the Local Government Board for sanction to borrow further sums for the purposes of the electricity undertaking, amounting to £14,727.

WIMBLEDON.—Tenders are to be invited for the supply and installation of a 1,000 kw. turbo-alternator with condenser, and two water-tube boilers with economisers, pipe-work, and feed-pumps, for the Council's electricity works, also for a remote control main high tension switchboard, and for the annual supply of flame arc lamp carbons from March 31st, 1908.

WORCESTER.—The Corporation invite tenders for the supply, delivery, and erection of the following plant:—A 400 kw. continuous-current steam generator; balancing dynamo; surface condenser. Copies of specification, &c. (fee one guinea, returnable), from the City Electrical Engineer, Mr. C. M. Shaw, to whom tenders by January 6th

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

ARGENTINE.—The Lacroze Tramway Co. has ordered 22 electric tramcars from the J. G. Brill Co. to replace those destroyed by fire early this year.

AUSTRALIA.—Tenders for the supply of telegraph, telephone, and electric light material for the year 1908 have been accepted from the following firms by the New South Wales Postmaster-General's Department:—British Insulated & Helsby Cables, Ltd.; India Rubber, Gutta Percha, and Telegraph Works Co., Ltd.; International Electric Co.; Vacuum Oil Co., Ltd.; and Siemens Bros. & Co., Ltd.

BAHAMAS.—It is stated that the contract for the municipal electric lighting plant at Nassau has been given to an American firm.

BLACKBURN.—The Board of Guardians has accepted the tender of Mr. H. Garstang, electrical engineer, for electrical repairs and the maintenance of fire alarms in the Union for the ensuing quarter.

BUENOS AYRES.—A contract has been let for supplying Government House with electric lifts.

COUNTY OF LONDON ELECTRIC SUPPLY CO.—An order has been placed with the British Thomson-Houston Co. for a Curtis turbo-generator set of 2,500 kw. capacity, complete with sub-base condensing plant, for the City Road Station (London) of the County of London Electric Supply Co. This is the fifth contract, and the sixth Curtis turbo-generator set ordered by the County Co. from the British Thomson-Houston Co., Ltd., aggregating 10,000 kw. in capacity.

ERITH.—The tender of the Woodville Electric Co. has been accepted for the installation of electric light at 48 municipal cottages in Brook Street, Belvedere.

FAVERSHAM.—An offer by Messrs. Drake & Gorham to supply "Hoadley" attachments to all the Nernst lamps in Faversham at 2s. 6d. each if the firm did the fitting, or 2s. 3d. if the Council did the fitting, has been received. It has been resolved that 50 of the attachments be obtained if they could be supplied at 2s. 3d. each, the electrical engineer to do the fitting.

SOUTH WALES.—The Treforest Electrical Consumers' Co., Ltd. (South Wales Power Co.), having decided to extend its plant, has placed an order with the British Westinghouse Electric and Manufacturing Co., Ltd., for one 3,000-kw. turbo-generator, 1,500 r.p.m., and complete high-vacuum surface-condensing plant fitted with the Westinghouse-Leblanc dry air pump.

STOKE-UPON-TRENT.—Subject to the sanction of the Local Government Board to the necessary loan, the following tenders have been accepted for plant in connection with the supply of electrical energy to Fenton:—Phœnix Dynamo Co., balancer and booster, £267 10s.; Switchgear Co., switching apparatus, £93 17s. 6d.

URUGUAY.—The tender of Messrs. Felten & Guilleaume for the supply of 39 km. of cable to the Monte Video electric supply works has been accepted.

WALTHAMSTOW. The tender of Messrs. Johnson & Phillips, Ltd., at £19 2s. 3d. for the supply of slate panels, in connection with the rearrangement of feeder cables at the generating station, has been accepted. The contract of Messrs. Chamberlain & Hookham, Ltd., for the supply of meters has been renewed on the same terms as previously.

The following tenders for the supply of paints and varnishes in connection with the tramway undertaking have also been accepted: R. F. Coulston, whitelead in oil; S. Mason, white lead, dry, ground pumice stone, lump pumice stone, turpentine; Docker Bros., blacklead, oil, black-brown; L. Berger, purple-brown, L.B. light Indian red, vermilion real dry, peacock-blue, olive green, chrome yellow, drop jet black, shellac brown, shellac white; Kearsley & Son, raw sienna, crimson lake, raw linseed oil; Kearsley & Son and Docker Bros., body varnish, best finishing body V, gold size, terebene; Everett's Stores, methylated spirit, benzoline.

The West Hampstead Accident.—At the conclusion of the police court proceedings at Marylebone on Saturday, against Signalman Hollis, who was on duty at the time of the collision between two electric trains in West Hampstead station in October, Mr. Plowden committed him for trial on a charge of manslaughter. He stated that the case was of great importance, and raised many points which could only be cleared up by a judge and jury, and it was for this reason, without prejudging the case, that he committed the accused signalman for trial.

Wireless Telegraphy in the French Navy.—A *Reuter's* telegram states that experiments with the Tissot system of wireless telegraphy have been made at Lorient on the Bay of Biscay, on board the cruiser *Kléber*. An attempt was made to open communication between the Eiffel Tower and the *Kléber* and the battleship *République*, which is at Toulon. The results were not quite satisfactory as no reply was received from the *République*. In the evening, however, communication was established with the battleship, and the telegraphists then tried to get into touch with Casa Blanca. The instruments on the *Kléber* were affected slightly, but ordinary communication was found to be impossible.

COMPANIES' MEETINGS AND REPORTS

SOUTH AMERICAN LIGHT AND POWER.—The annual meeting was held on Tuesday, when it was explained that the holding of the meeting had been delayed on account of the non-arrival of the auditor's figures from Bahia Blanca. The balance-sheet figures, which were on their way over, showed a small balance, which would have been greater but for the expense incurred in transferring all the overhead wires underground. The report was adopted conditionally upon the figures being subsequently certified. At an extraordinary meeting held later, the issue of 50,000 ordinary shares at £1 each was sanctioned.

SUNDERLAND DISTRICT ELECTRIC TRAMWAYS.—The report for the year ended October 31st last states that there is a loss on the year's working of £4,723, after deducting debenture interest, bringing the loss to date up to £12,056. This will be slightly reduced by a payment by the Durham Collieries Electric Power Co., Ltd., being royalties for current sold during the twelve months under their agreement with the tramway company. The actual amount has been referred to arbitration. Compared with last year the traffic receipts at Sunderland show an increase of £2,594. The cost of working to receipts comes out at 75·41 per cent. as against 75·76 per cent. last year. In view of the necessity for raising further capital, the Board has for some weeks been engaged in formulating a scheme which would be acceptable to the debenture holders and shareholders and after consultation with the trustees for the debenture holders and some of the largest preference and ordinary shareholders, they have decided that the best way would be to create prior lien bonds up to £20,000, with a currency of ten years, to issue £5,000 at once, and £10,000 as and when required during the next twelve months, holding £5,000 in reserve for contingencies. It is thought that with the judicious expenditure of this further capital on the undertaking the traffics will show a considerable expansion. When the receipts grow so as to show a surplus profit it will then be necessary to readjust the capital of the company, as without some such readjustment a distribution of dividends would appear to be impracticable.

At the meeting on Monday, the report and accounts were adopted, after a lengthy speech by the chairman, Mr. C. S. Cockburn, J.P. The chairman stated that he felt relieved the position was not worse, and that a receiver was not in possession. Even this would still be necessary if the debenture holders did not agree to the proposals of the Board in regard to raising new capital. When he joined the Board in the spring he found that of the £20,000 second debentures authorised at the last annual meeting, it had only been possible to issue some £14,000, and that there were debts and liabilities totalling about £10,000. He had to take £5,000 of these second debentures himself, and to get some of the creditors to take a portion of their debts in these second debentures instead of insisting on cash. He was glad of this opportunity of thanking those creditors who thus assisted the company. It was not an enviable position to assume—to travel round the city of London and the town of Sunderland to persuade irate and insistent creditors to reduce their just claims for payment for work done and then to ask them to accept second debentures instead of cash in part payment of those claims. It was a *rôle* he had never had to assume on his own behalf and in view of his experiences it was a position he would take very good care never again to take up for any company. They now owed to tradesmen and others the sum of £2,885, and were short of the debenture interest on January 1st by £2,100; hence the Board's decision to ask the shareholders to sanction the borrowing of £5,000 at once.

In enumerating the causes which have led up to the present position, the chairman mentioned the installation of the gas plant, which had been a constant source of trouble, the two serious accidents upon the system, the issue of miners' tickets, which it was ultimately found were being worked at a loss, the bad weather during the past year, and the purchase of fifteen French cars which, he said, had he the capital, he would scrap at once. Again, there were the track subsidences due to the colliery working, which was a danger they would always be exposed to. The directors, however, were quite convinced that the poulation was there to be carried. Dealing with the details of the working expenses he pointed out that for the year from November 1st, 1906, to October 31st, 1907, the receipts per car mile come out at 7·608d., and the power costs 0·790d. per unit. The total works costs showed 6·174d., and the net revenue came out at 1·434d. The units per car mile worked out at 1·685. On a car mileage of 758,532, the passengers carried were 3,741,096. The receipts per passenger were 1·542d. and the costs per passenger 1·251d. Other details having been referred to, the report and accounts were adopted as stated above. At a subsequent meeting of the debenture holders, the chairman stated he believed the company had turned the corner, but at the same time, in connection with the expenditure of the new £20,000 capital, the Board would welcome a committee to co-operate. He also stated that the company's bankers had agreed to lend up to £2,500 at once, if wanted, on his personal guarantee, which, if the scheme went through, he had

Digitized by Google

no hesitation in giving. An extraordinary general meeting of the company followed, at which the scheme was also sanctioned.

UNDERGROUND ELECTRIC RAILWAYS COMPANY OF LONDON.—At the annual meeting on Monday last week the report given in full in our issue for December 19th was adopted. Sir Edgar Speyer, who presided, made no speech, but stated that, in view of the fact that the directors hoped early in the new year to put before the shareholders a scheme dealing with the finances of the company, he thought it better to reserve his remarks until then.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f., port of arrival, quoted on Tuesday night was £63 10s. to £64 10s. per ton.

ARMORDUCT MANUFACTURING CO., LTD.—Mr. F. Smart, who for many years was connected with the General Electric Co.'s Newcastle branch as assistant manager, has been appointed manager of the Newcastle branch of the Armorduct Manufacturing Co., Ltd.

DINNERS, &c.—The annual dinner of the engineering staff of the Croydon Corporation Tramways was held on Saturday, December 14th, Mr. Harris, the tramways engineer, presiding.

On Saturday, December 21st, the employees of Messrs. A. Reyrolle & Co., Ltd., Hebburn, held their fifth annual dinner. Mr. Reyrolle took the chair, and stated that although many other electrical firms had experienced a slackening of orders, he was glad to say that they had had an extremely busy year.

The second annual fancy dress ball of the Robertson Social and Athletic Club was held at the Brook Green Works, Hammersmith, on December 21st.

DISSOLUTION OF PARTNERSHIP.—The partnership between F. J. Robinson and W. J. Silvester, Electrical and General Engineers, 21 Collingwood-street, Newcastle-upon-Tyne, has been dissolved by mutual consent. All debts by F. J. Robinson, who continues.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the Premier Accumulator Co., Ltd., will be held at 10 Ironmonger Lane, London, E.C., on January 27th at 12 noon, to hear the liquidator's account of the winding up.

Creditors in the bankruptcy of T. A. Cotton, carrying on business as an electrical engineer as Cotton Bros., 78 King Street, Manchester, are requested to send particulars of their claims to Mr. Arthur Nicholas, 63 Bridge Street, Manchester, by January 10th.

The re-examination of W. D. Palmer, electrical engineer, 50 Wellington Street, Glasgow, was heard last week and adjourned. The statement of affairs shows a deficiency of £5,952.

WESTINGHOUSE-BREMER PATENTS.—The British Westinghouse Electric & Manufacturing Co., Ltd., inform us that they have now received the decision of the Comptroller-General of Patents, and have, therefore, issued a writ against Messrs. D. Santoni & Co. (1906), Ltd., for infringement of the Westinghouse-Bremer flame arc-lamp patent.

MISCELLANEOUS CITY NOTES

AMERICAN WESTINGHOUSE COS.—The Washington correspondent of *The Times* states that an important industrial fact made public is that arrangements are nearing completion to put Mr. George Westinghouse's concerns on a sound basis again, and to discharge the receivers. Official reports indicate that the concerns are entirely solvent and were doing a profitable business at the time of, and for years before, the receivership.

HAVANA TELEPHONE CO.—The half-year's interest, due January 1st, on the 5 per cent. first mortgage debentures, will be paid on and after that date by the company's bankers, Messrs. Frederick J. Benson & Co., 11 and 12 Blomfield-court, London, E.C., on the production of provisional scrip certificates, which must be left four clear days for verification.

COMPANIES TO BE STRUCK OFF REGISTER.—The following are among the companies which will be struck off the register within three months from December 24th, and dissolved, unless cause is shown to the contrary. Electrical Inkless Printing Syndicate, Ltd.; Electric Printing and Publishing Co., Ltd., Electrophone, Ltd.; Medical Electrical Institute, Ltd. The Electric Printing and Publishing Co. was registered in 1894 with a capital of £6,000, to work a reproduction process, and has no connection with any electrical journal. The Electrophone, Ltd., was registered in 1894. Another company of this name is now carrying on business.

NEW PUBLICATIONS

Proceedings of the American Institute of Electrical Engineers. December, 1907. (New York: The Institute.) 50c.

"The Science Year Book, 1908." (London: King, Sell & Olding). 5s.

APPOINTMENTS AND PERSONAL NOTES

MR. E. P. BARFIELD, who has filled the position of lamp manager to the General Electric Co., Ltd., for the past eight years, has resigned in order to take up a similar position with Messrs. Siemens Bros. Dynamo Works, Ltd.

For the positions of traffic superintendent and rolling-stock superintendent at Halifax, the following have been selected for final decision:—Traffic superintendent: R. F. Rogers, Leeds; James D. Caird, Aberdeen; E. Cloney, London; Thomas Tate, Wakefield; E. Lafferty, Preston; and H. H. Saunders, Lowestoft. Rolling-stock superintendent: H. Hartley, Darlaston; Thomas Wilkinson, Haydock; E. Sidgwick, Stalybridge; J. W. Galloway, Rochdale; J. H. Burton, Wakefield; and E. Metcalfe, London.

MR. ARTHUR JACOB informs us that he has undertaken the control of the commercial organisation of The British Aluminium Co., Ltd., 109 Queen Victoria Street London, E.C., and has, in consequence, severed his connection with Messrs. Siemens Brothers Dynamo Works, Ltd., London.

NEW COMPANIES

ELECTRICAL APPARATUS CO.—This company was registered on December 23rd, with a capital of £3,500 in £1 shares, to acquire the business of electrical engineers carried on by E. Schattner, F. H. Epstein, R. Amberton, and R. Behrens, at Caxton House, Westminster, as the Electrical Apparatus Co., and to carry on the same and the business of electricians, suppliers of electricity, manufacturers of, and dealers in, motors, dynamos, accumulators, storage cells, insulators, lamps, and other electrical apparatus and appliances, &c. The subscribers are:—F. Epstein, electrical engineer; Miss C. Amberton; R. Behrens, electrical engineer; R. Amberton, electrical engineer; J. H. Epstein; E. Schattner, electrical engineer; Mrs. K. Schattner; T. A. Hargreaves. No initial public issue.

GASOL ENGINEERING CO.—This company was registered on December 24th, with a capital of £500 in £1 shares, to carry on the business of mechanical, electrical, and marine engineers, millwrights, ironmasters, iron and brassfounders, manufacturers of steam engines, boilers, gas and electric generating appliances, gas and electric engines, motors and machinery, &c. No initial public issue.

LAMINATED GEARS.—This company was registered on December 21st, with a capital of £10,000 in £1 shares, to adopt an agreement with S. W. B. McGregor, and to carry on the business of ironfounders, mechanical and electrical engineers, electricians, manufacturers of engines, boilers, and machinery, tool makers, &c. No initial public issue. Registered office: 9-10 St. Mary-at-Hill, Eastcheap, E.C.

MITCHAM ELECTRIC FAN CO.—This company was registered on December 20th, with a capital of £10,000 in £1 shares, to acquire and turn to account inventions relating to the production, storage, application, distribution, and use of electricity, to adopt an agreement with the Dynamic Syndicate, Ltd., and to carry on the business of manufacturers of and dealers in electric fans, electric tools, induction coils, &c. No initial public issue. Registered office, 6 Broad Street Place, E.C.

RELIANCE INCANDESCENT CO.—This company was registered on December 24th, with a capital of £6,700 in £1 shares, to carry on the business of ironmongers, electric lighting and heating, and general engineers, gasfitters, manufacturers of and dealers in glassware, and lighting and heating accessories, &c., and to adopt an agreement with A. Gross and a deed of covenant between the said A. Gross of the first part, A. Weiss of the second part, A. C. H. Raetsch, and C. H. Thoem of the third part, and the company of the fourth part. No initial public issue. Registered office, 50 Rye Lane, Peckham, S.E.

SHEFFIELD SHERARDISING CO.—This company was registered on December 21st, with a capital of £20,000 in £1 shares, to acquire the sole and exclusive licence for Sheffield and the surrounding district under certain patents for the depositing of metals on metals known as the "Sherardising and analogous process;" to adopt agreements (1) with P. Dawson, and (2) between the Sherardising Syndicate, Ltd., of the first part, P. Dawson of the second part, and this company of the third part, and to carry on the business of galvanisers, zinc workers, steel and ironmasters, founders, manufacturers, and blenders of alloys, electro-platers, engineers, &c. No initial public issue. The number of directors is not to be less than three nor more than five.

WM. WHITEHOUSE & CO.—This company was registered on December 24th, with a capital of £50,000 in £1 shares, to take over as from December 31st, 1906 the business carried on by W. Whitehouse and H. Pinnell (trading as "Wm. Whitehouse & Co."), at Empire Works, Brueton Street, and Lawrence Street, Birmingham, and to carry on the business of gas and electric fittings, manufacturers, brassfounders, art metal workers, &c. No initial public issue. Registered office: Empire Works, Brueton Street, and Lawrence Street, Birmingham.

SUMMARY

The controversy with regard to priority of invention of "graded" cables is finally settled by our publication this week of the original patents taken out by Messrs. Pirelli & Co. and Mr. O'Gorman respectively. Although Mr. Jona, in Messrs. Pirelli's patent, may claim to have been the first to use rubber with a layer of paper over it for high-pressure cables, Mr. O'Gorman must be credited with the idea of using layers of paper of different specific inductive capacities with the express purpose of equalising the voltage gradient. Mr. O'Gorman was also the originator of the lead sheath directly over the stranded copper conductor, to compensate for the irregularities of surface. (Page 36.)

In a description of some of the features of the Windsor Essex and Lake Shore Rapid Railway, the first single-phase railway to be put to work in Canada, attention is drawn to the use of three-wire alternators, which give 6,600 volts for the direct supply of the trolley, and also supply a single-wire 13,200-volt feeder to a distant sub-station. (Page 38.)

A 1,500-volt continuous-current railway has been recently set to work in one of the southern valleys in Switzerland, on a route formerly worked by steam. Current is derived from a water-power station, from which three-phase transmission is taken to sub-stations equipped with motor-generators. Span-wire overhead construction is used, and each car is provided with two pairs of 750-volt motors and multiple-unit control. (Page 39.)

In reporting upon the accident to a Birmingham Corporation tramcar, on October 1st, by which two passengers died from injuries received, and twelve were injured more or less seriously, Lieut.-Col. H. A. Yorke states that the immediate cause of the disaster was the action of Inspector Hall in taking the car down Warstone Hill with a defective magnetic track brake, and experimenting with that brake on the incline. Had he applied the hand brake before starting down the incline no accident would have occurred, as the gradients are such that the car might well have been controlled by means of the hand brake only, the only precaution necessary being that the hand brake should be applied at the commencement of the hill, so that the speed of the car should be checked from the outset. (Page 42.)

A vertical rotary converter, with a capacity of 2,000 kw., has been installed in a sub-station in Chicago. This is said to be the largest vertical shaft machine of its class yet made. (Page 43.)

The recently built Hotel Adlon in Berlin has a particularly complete installation of telephones, bells, and other signalling apparatus, clocks, and fire alarms.

Digitized by Google

The bells are placed so as to be inaudible from the rooms, and an elaborate arrangement of signal lamps takes the place of electro-magnetic indicators. (Page 44.)

A NEW automatic electric block signalling system is in use upon the Philadelphia and Western Railroad. The features of the system are the use of both rails of each track, as the returns for the current, cross-bonding facilities between all rails of both tracks at the ends of all track circuits. Single-arm, two-position home signals arranged on the normally clear principle are employed with an overlap. The signals average about 3,300 ft. apart in some districts, on account of the heavy traffic, but in other places there is uniform over-lap of 3,700 ft., allowing headway of about five minutes. (Page 45.)

A DETAILED description is given of the Pringle "tangential" trolley-wire suspension. (Page 46.)

A 100-TON electric crane of the revolving jib type, with travelling crab, which presents some interesting features, has recently been erected for the Dublin Port and Docks Board. (Page 48.)

WE publish a detailed description of the new trunk telephone exchange in Bradford, opened by the Post Office last November. The exchange embodies all the most recent devices for facilitating the utmost utilisation of the trunk lines without waste of time. Our description includes details of the arrangement by which a telegraph circuit is superposed on the lines for the purpose of transmitting all service directions, so that the telephone circuit is used for remunerative conversations only, and it also contains a description of the time check which has been evolved by the Post Office for assisting the operator to control the duration of a conversation by giving a lamp signal when the three minutes have expired. (Page 49.)

A NEW 750 kw. single-phase turbo-alternator has been installed at Eastbourne, which forms the most up-to-date item in the equipment of an undertaking dating from the early 'eighties, where the original belt and rope-driven alternators have given place later to machines driven by various types of moderate and high speed reciprocating engine. (Page 52.)

A PAPER by Mr. W. E. REED in an American contemporary, considers the question of electrical rolling mill driving, more especially with regard to equalising systems for dealing with rapid variations of load. Some examples of actual equipments are also summarised. (Page 55.)

THE production of artificial fertilisers from atmosphere nitrogen is forging ahead, and a further 4,700 h.p. plant has been erected in Norway for its manufacture. According to the figures of Mr. F. T. SNYDER the reduction of zinc ores in an electric stack-furnace is more economical than by means of the old-fashioned retorts. There is a good opening in this direction for the introduction of electric-thermic methods, because the zinc metallurgical process is one of the most wasteful of all metallurgical methods. The Norton Co., of Worcester, Mass., are manufacturing a new abrasive by purifying bauxite, and then fusing it in the electric furnace. Other notes in connection with "Electrochemistry and Electrometallurgy" are upon a new white lead and lead chromate process, and upon the recovery of tin from tin scrap. (Page 57.)

SOME additional particulars are now available of the electric locomotives under construction for the Cascade Tunnel of the Great Northern Railway of America, which will form the first example of three-phase traction in the United States. (Page 57.)

UNDER "Electrical Science, British and American," are notes on a supposedly new gas occurring in cathode ray tubes, and on the question of the trustworthiness of standard cells for the purposes of measurements of precision. In the Papers abstracted in the Continental Section, ABRAHAM and DEVAUX-CHARBONNEL indicate the principles underlying the efficiency of telephones, and BÉCLÈRE criticises Vaillant's radioscopic test for death. (Page 58.)

SOME figures from a report by a firm of accountants entrusted with an investigation of the affairs of the American Westinghouse Companies are given on page 59.

A LETTER from Mr. G. WILKINSON comments on a note in one of our contemporaries, and puts forward the claims of live steam heating against exhaust steam heating. (Page 59.)

AMONG the specifications published by the Patent Office on Thursday last is one by BABB, CHAPMAN, & COCKSHOTT, which comprises a new method of braking for electric motors on railways or tramcars. RHODES and the RHODES ELECTRICAL MANUFACTURING CO. have patented a new method of securing the segments of commutators, without the use of solid rings. SIEMENS BROS. DYNAMO WORKS, LTD., have patented a new overload cut-out, with a time-limit device of a new character. P. MACGAHAN has a new synchronising device, which does away with auxiliary transformers, and has no direct connection between bus bars and the machine being paralleled. The BRITISH THOMSON-HOUSTON CO. have amended their patent No. 8,680, of 1904, relating to systems of control of electric motors, and have added a new clause to the specification. (Page 60.)

THE Blackburn Town Council are opposing the revival and extension of time of the Blackburn, Whalley and Padiham Light Railways Order. The Bury Town Council have decided that, as the facilities for coaling and condensing are inadequate at their present station, a new works should be built, and a site has been already obtained. Dublin electricity accounts for the year ending March 31st, 1907, show considerable profits and progress. The Hackney Borough Council has agreed to the equipment, by the L.C.C., of the tramway routes in the borough, on the overhead system. The Hackney Council decided to start a showroom and sales department for electrical fittings. A clause has been inserted in the agreement between the Hammersmith Council and the Franco-British Exhibition (see ELECTRICAL ENGINEERING, January 2nd, 1908, p. 28), relating to penalties in case of a failure of supply. Hull has been troubled lately by explosions in cable boxes due to gas. The report of the Consulting Engineer to the Oxford Corporation, on the working of the Dolter system of tramway electrification, does not favour that system as applicable to Oxford. The Woolwich Borough Council have formulated new rate systems by which time switches are done away with in certain cases, and a flat rate of charge instituted. Consumers with a power supply are to be allowed to use that supply for lighting, provided the lighting does not exceed 7 per cent. of the total energy used. (Pages 61-63.)

THE Glasgow Corporation are inviting tenders for a 4,000 kw. turbo-alternator running at 750 r.p.m.; some machine tools are required for the tramways department of the Manchester Corporation, and a report is to hand that the Vienna Municipality intends to issue a loan of some £10,000,000 for the extension, among other municipal works, of the electric lighting and traction undertakings. A Paris firm of electrical contractors ask for samples, &c., from British makers of luminous decorations and art lighting for exhibit at the Marseilles Exhibition. Among the municipalities at home who are in the market for electrical goods are the London County Council, the Plymouth and Rotherham Corporations, and Barnes and Finchley Urban District Councils. (Page 63.)

Digitized by Google

THE Electricity Committee of the Manchester Corporation recommend that Mr. S. L. Pearce, the Chief Electrical Engineer, be re-engaged for four years at a salary of £1,100 per annum for the first two years, and £1,200 for the remaining two years. There were 200 applicants for the post of Electrical Engineer to the Carlisle Corporation, and Mr. O. F. Francis, of Kirkcaldy, has been appointed. Mr. Keats, Acting Electrical Engineer to the Woolwich Borough Council, has been appointed Electrical Engineer. (Page 65.)

A RESOLUTION confirming the reduction of the capital of the South London Electric Supply Corporation by £65,000 was confirmed on Tuesday. Subscriptions are being invited for £147,300 four per cent. debentures in connection with the purchase of the undertaking of the City of Wellington Electric Light & Power Co., by the municipality. A final distribution of £1 2s. 7d. per share has been made to the shareholders of the London Southern Tramways, Ltd. A feature of our stock and share list is a general rise in London electric railway stock. (Page 66.)

THE similarity between the supply of electrical energy and the sale of tobacco is but slight; nevertheless our esteemed contemporary, the *Elektrotechnische Zeitschrift*, has found it necessary to devote a long and excellently written leading article to bring this home to the German public. This action on the part of the paper, which is the official organ of the German electrical industry, was certainly needed, for a proposal to make the supply of electrical energy for all purposes a government monopoly, has been put forward with some degree of assurance by a Berlin newspaper, which represents semi-officially the views of the Government, and it has been announced that it has been promised the sympathetic consideration of the National Liberal party. Our contemporary points out that the results of such a monopoly—which we would remark would probably be more on the lines of the postal and telegraph monopoly of this country than of the tobacco monopoly existing in some cases abroad—would be little short of a disaster, not only to the German electrical industry, but to every industry in which electrical energy is utilised.

"The effective application of electricity begins with the initial supply of raw material. The machinery for preventing the water rising in mines is electrically driven; the material is obtained by electric drilling, and it is raised, crushed, melted, rolled, turned, and welded by electricity. From the ore to the armour plate on the one hand, and to the sewing machine on the other hand, no step in the manufacture is taken which is not at the present day made with the assistance of electrical energy. The surplus energy in the whole range of the industrial districts is employed to good purpose by means of the electric current. . . . And the Government is now to step in and take the free generation and utilisation of electrical energy out of the hands of the industries themselves, in order to sell them at a profit, an essential necessity of their existence."

The above is a free translation of our contemporary's just condemnation of a scheme which can only be likened to the nightmare that might arise in the brain of one who has combined, not wisely but too well, the study of Plato's "Republic," More's "Utopia" (or some of the various absurd modern variations on their theme written with the purpose of advancing Socialistic ideas), with an over-indulgence in Christmas fare. Not only would such a measure as the threatened electricity supply monopoly seriously affect the works using the electrical energy which they produce as a by-product, but it would also prevent them from selling any surplus electrical energy outside. Moreover, the user of private generating plant would take an analogous position to the user of an illicit still. Doubtless those who defend the measure would point out that all this is easily adjustable by the issue of free licences in deserving cases, but this would prove almost unworkable in practice, and might lead to grave irregularities. Moreover, it would appear that this is not the intention, for our contemporary speaks of the taxation of electrical energy so generated, and compares it with the political-economical equivalent of taxing raw material. We need not follow the *Elektrochemische Zeitschrift* into its review of the effect that the passing of such a measure would have on the employees and on the manufacturers of electrical plant. The proposal will be so condemned by all the leaders of the electrical industry and by those who understand the conditions prevailing, that there is little likelihood of its being proceeded with. We trust that a like experiment will never be threatened in our own country.

THE advantages of single-phase traction are more particularly apparent in the case of lines of some length. Prominent among them is the simplification of the sub-station equipment as compared with that required by the system of three-phase transmission and rotary converters which not long ago could be practically regarded as standard practice in America. In addition to the substitution of stationary transformers in the sub-stations for running plant, there is, in cases where the transmission as well as the distribution is single phase, also the possibility of effecting a simplification of the transmission line by the use of two wire feeders instead of the three wires necessary for a three-phase circuit. In another column the equipment of a Canadian single-phase line is described, in which, by an ingenious arrangement, a further simplification is effected, and the feeder to the single sub-station, which is all that is required by the moderate length of the line, consists only of one wire. As indicated in the article, this is done without transformers in the generating station by means of what may be termed three-wire single-phase alternators, from which two different potentials, one for the trolley and one for the feeder, are obtained. It is probable that the number of cases in which this device is applicable will be somewhat limited, and some problems may arise from the alternator designer's point of view, owing to the possibility of different power factors in the high and low voltage parts of the circuit; and there may also be inductance troubles which would affect the transmission line in the case of long routes. The simplicity of the system, however, certainly renders it worthy of study.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 9TH.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, London. Paper to be read:—"Cost of Electrical Power for Industrial Purposes," by J. F. C. Snell.

FRIDAY, JANUARY 10TH.

Electro Harmonic Society.

8 p.m. Smoking Concert in the King's Hall, Holborn Restaurant.

SATURDAY, JANUARY 11TH.

Junior Institution of Engineers.

3 p.m. Visit to the L.C.C. Reconstruction Works in South Lambeth Road, and Motor School, Car Shed, and Substation at Clapham.

Rugby Engineering Society.

Visit to the Franco Exhibition Buildings at Shepherd's Bush, London. Train leaves Rugby 12.42 p.m.

[Continued on next page.

Digitized by Google

MONDAY, JANUARY 13TH.

Institution of Electrical Engineers: Leeds Local Section.
7.30 p.m. Meeting at the University, Leeds.

Dick, Kerr Engineering Society.
8 p.m. Ordinary meeting. Paper to be read:—"Electric Lighting of Railway Trains," by H. A. Cox.

TUESDAY, JANUARY 14TH.

Institution of Electrical Engineers: Manchester Local Section.
7.30 p.m. Ordinary meeting at the University (Physical Laboratory). Postponed from January 7th. Paper to be read:—"Magnetic Oscillations in Alternators," by G. W. Worrall.

Institution of Electrical Engineers: Glasgow Local Section.
8 p.m. Ordinary meeting at 207 Bath Street. Paper to be read:—"Cost of Electrical Power for Industrial Purposes," by J. F. C. Snell.

WEDNESDAY, JANUARY 15TH.

Institution of Electrical Engineers: Birmingham Local Section.
7.30 p.m. Ordinary meeting in the University. Paper to be read:—"The Heat Conductivity of Iron Stampings," by T. M. Barlow.

Institution of Electrical Engineers: Students' Section.
7.30 p.m. Meeting at 92 Victoria Street, London, S.W. Paper to be read:—"Electrification of the Mansfeld Copper Mines," by H. R. Speyer.

THURSDAY, JANUARY 16TH.

Union Electric Co.
7 p.m. Staff dinner at the Café Royal, Regent Street, London.

Rugby Engineering Society.
8 p.m. Ordinary meeting. Paper to be read:—"The British Locomotive," by A. W. S. Greame.

"GRADED" CABLES

IN view of the discussion which took place at the Institution of Electrical Engineers, and subsequently in our correspondence columns, with regard to graded cables, and the introduction into it of the question as to whether their invention should be righly ascribed to Mr. Mervyn O'Gorman, or Mr. Jona of Pirelli & Co., we have obtained a copy of the Italian patent specification to which reference was made in Mr. Jona's letter to us (published in our issue of December 5th, 1907). The patent is dated April 20th, 1900, and, as Mr. Jona rightly pointed out, relates to the cable which Mr. Raphael saw at the Paris Exhibition a month or two later, and described in *The Electrician*, with which paper Mr. Raphael was then connected. There is, however, no specific mention of "grading" as a means of equalising the voltage gradient, and apparently the fact that the insulating materials employed had different specific inductive capacities was not the reason for adopting the design in question. It is also clear, that so far as anticipation is concerned, although Mr. Jona (or rather Messrs. Pirelli & Co.) were the first to patent the use of rubber with layers of paper over it for high pressure cables, Mr. O'Gorman was undoubtedly the first originator and patentee of the idea to use layers of impregnated papers of different specific inductive capacities. Mr. O'Gorman was also the inventor of the use of the lead sheath directly over the stranded copper conductor (to compensate for the irregularities of its surface), which was neither used by Mr. Jona in his 1900 cable nor mentioned in the Pirelli patent.

For the purpose of comparison, we publish, in addition to a translation of Messrs. Pirelli & Co.'s Italian patent, the text of Mr. O'Gorman's two British patents on the subject.

Messrs. Pirelli & Co.'s patent of April 20th, 1900, is as follows:—

A New Type of Insulated Cable for Very High Pressures.

The cable forming the subject of the present Patent Application is constituted as follows:—The copper conductor *S* is surrounded by a first insulating layer of vulcanised rubber *G*, and subsequently by other layers *R*, composed of paper or textiles, or of paper only, or textiles only. If the cable has only one conductor (Fig. 1), drying and impregnation with insulating materials is next proceeded with, as is commonly done in cables insulated with paper and textile fabrics only.

If the cable has several conductors (Fig. 2), the conductors, insulated as before by means of rubber, paper, and textiles, are then stranded together with fillings *T* of textiles. Outside this strand is generally placed a covering *U* of other layers of paper and textiles, or paper only, or textiles only. The whole thus constituted is then dried and impregnated with insulating substances, as usual.

The cables of one or several conductors so composed are then covered by a lead tube *V* and protected by an armouring of iron *Z*, with a further covering of textiles *X*, which may eventually be added externally as in other subterranean cables (see Fig 2), or this protection is omitted as in Fig. 1.

The advantages of this type of cable are the following:—

(1) In the cables with one conductor: In the internal portion of the insulating mass there is a dielectric of high insulating power and of great electrostatic rigidity. In the external portion of this mass there is a dielectric which does not offer this property in such a high degree. Now, since the dielectric vulcanised rubber costs much more than that composed of paper and textiles, the arrangement described gives a better utilisation of this costly dielectric.

(2) In the cables of several conductors bound together: The advantages of this type are specially felt in cables with several conductors, where, besides the above advantage, there are several others. Above all, a cable constructed exclusively with paper or textiles impregnated with insulating substances is not suitable for very high tensions, for which, in fact, the best makers have generally adopted rubber as an insulator. But this has the

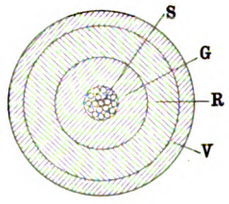

FIG. 1.

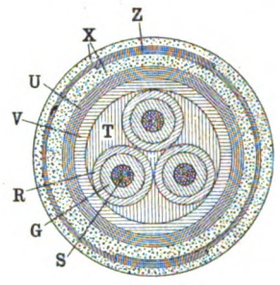

FIG. 2.

inconvenience of the gaps left in the strand between the cores. Further, the insulating thickness existing between the conductor of one core and the conductor of another core would not be proportional to the thickness of insulator existing between each conductor and the external lead, which is earthed, and so the dielectric would be more strongly stressed between the conductor and the outer lead than between two cores. In the type of cable which is the subject of the present patent application, another insulating layer may, on the other hand, be added outside the strand of the cores, so as to put the dielectric under equal stress in all directions.

The claim of Messrs. Pirelli & Co.'s Patent is as follows:—

The construction and application of a cable in which the insulator is mixed, *i.e.*, rubber inside close to the conductor, and paper and textiles, or paper only, or textiles only, in the outer part of the insulating layer, and that either in simple cables of one conductor or in multiple cables with two or more conductors.

It may be added that the addition of a worming (or "filling," as it is called in the Italian patent) to make up a strand of cores into a circular shape before placing additional layers of insulating material between the cores and the lead, was known and used regularly by British cable makers many years before the date of this patent, and it is probably for this reason that it is not included in the claim, although it is mentioned as a particular feature of the cable in the body of the specification.

Mr. O'Gorman's patent, No. 1,568, of January 23rd, 1901, relates to the grading of cables. The complete specification is as follows:—

The object of this invention is to reduce the thickness of the insulation on electric cables and to cheapen the cost of manufacture and also to reduce the loss of energy in the dielectric. In cables as hitherto constructed a number of coats of insulating material have been arranged in an arbitrary manner, for instance, the more expensive materials have been put nearest the conductor so as to economise the quantity used or the more waterproof materials put outside.

Digitized by Google

I call "curve of voltage" a curve showing the relation between the distance from any conductor and the voltage at that distance within the insulation, and the slope of the tangent to this curve at any point I refer to as the voltage gradient at that point. I call a "homogeneous" insulating coat, an insulation possessing in all parts of any section the same specific inductive capacity, specific disruptive strength and specific conductivity, but sub-divided into layers where such sub-division is contemplated in the finished cable.

According to my invention insulating materials are selected and arranged in a large number of coats, either (1) in such a manner that the specific inductive capacity of the coats decreases outwards from the conductor and that the specific inductive capacity of each coat is proportional to the voltage gradient which would occur at the distance of that coat from the conductor if the conductor were in a homogeneous insulating coat of the thickness required according to my invention, or (2) in such a manner that the specific conductivity of the dielectric decreases outwards from the conductor, and that the specific conductivity of each coat is proportional to the voltage gradient which would occur at the distances of that coat from the conductor if the conductor were in a homogeneous insulating coat of the thickness required according to my invention, or (3) in such a manner that the specific disruptive strength of the dielectric decreases outwards from the conductor, and that the specific disruptive strength of each coat is proportional to the voltage gradient which would occur at the distance of that coat from the conductor if the conductor were in a homogeneous insulating material of the thickness required according to my invention. It must be remembered that the specific disruptive strength of many materials is greater for thin layers than for thick.

My first alternative I may employ for cables intended for alternating potential differences. My second for cables with continuous potential differences. My third may be used in combination with either my first (in the case of alternating potential differences, or with my second alternative method (in the case of continuous potential differences), when there is difficulty in obtaining materials having the full range of capacities or conductivities. When a cable is to be used for alternating and continuous potential differences, I may employ methods (1) and (2) simultaneously. It is to be noted that alternations in disruptive strength, as such, need make no change in the distribution of stress within the thickness of the layers, unless the other specific qualities are altered, and, therefore, are not essential when the potential difference to be established between the parts of the cable is small.

The coats should be as numerous as possible, and may be entirely distinct, but a slight intermingling of the material of different coats may be unavoidable, and may be no great disadvantage where it helps the regularity of the graduation. The variations of the gradient between any conductors in a homogeneous dielectric can be determined; *e.g.*, between two concentric cylindrical conductors the curve of gradients, which is steep near the inner conductor, can be mathematically obtained. The thickness of insulation determined by any of my alternative methods may be the same, and my choice of method may then depend on the rarity and cost of applying the materials required by the different methods. The number of layers in many materials, such as rubber, gutta percha, or paper, &c., cannot be increased indefinitely on account of expense, but I keep to the suggested arrangement as nearly as economy and permanency will permit.

By adjusting the qualities of the dielectric material in each coat according to my invention, the total radial thickness of insulation necessary is greatly diminished; *e.g.*, with a single or concentric conductor, and any given permissible voltage gradient, the total thickness may be made proportional to the voltage which the cable has to withstand. Any of the ordinary insulating materials may be employed, and their specific inductive capacity $\frac{\text{or}}{\text{and}}$ their specific conductivity $\frac{\text{or}}{\text{and}}$ their specific disruptive strength may be varied by impregnating or compounding them with "loading" materials differing in specific inductive capacity $\frac{\text{or}}{\text{and}}$ specific conductivity and specific disruptive strength, such as vulcanised rubber, gutta percha, bitumen, celluloids, hydrocarbon oils, mica, or the like. Where insulating materials capable of becoming fluid and of different specific conductivities and capacities are used, they may be so arranged that the materials of high conductivity have also a high capacity, so that their tendency is rather to come towards than to diverge from the places where their specific conductivity $\frac{\text{or}}{\text{and}}$ capacity is required to be proportional to the voltage gradient.

In many cases, cables may, whether their normal potential difference be continuous or alternating, be subjected to very high alternating pressures far in excess of the working maximum, and in such cases the graduation of the specific properties of the various coats should take into account this extra alternating maximum. For example, if I wish to insulate in accordance with this invention a single lead-covered cable of 37 strands each of No. 14 standard wire gauge to withstand 15,000 volts, I choose what working stress I consider safe for all the substances which I propose to employ, say 20,000 volts per centimetre. This determines the thickness of insulation, in this instance, say, 0·28 in. I now fix upon the largest number of coats, in which it is commercially advisable to divide the insulation, but I choose five coats in this instance having thicknesses of 0·08″, 0·05″, 0·05″, 0·05″, and 0·05″ respectively. For the coat of 0·08″ thick, where the gradient is least, I seek a substance which has a combination of properties in which the disruptive strength is not less than 20,000 volts per centimetre, and the specific capacity is relatively small (for example, manilla or other thin and uniform paper impregnated with rosin oil), and I obtain by experiment on the sample used or from reliable published tables of physical constants, a numeric which represents this.

In my present example this numeric is 2, and this numeric will therefore have to correspond with the mean value of the stress in that layer of 15,500 volts per centimetre. For the second layer, I require a numeric of 2·27; for the third layer, I require a numeric of 2·57; for the fourth layer, I require a numeric of 2·93; for the fifth layer, I require a numeric of 3·4; and I obtain these various numerics by adding castor oil to the rosin oil used for impregnating the paper. The exact quantities will depend upon the resistance and capacity of the castor oil, which varies in commercial samples, but in this particular instance the quantities chosen were:—For the second layer, 9·5 per cent. castor oil; for the third layer, 20·5 per cent. castor oil; for the fourth layer, 33·0 per cent. castor oil; for the fifth layer, 50·0 per cent. castor oil.

The cable of this example is intended to withstand a voltage alternating at an ordinary frequency of commercial supply currents.

One method of obtaining the exact percentage of castor oil to add is to make a series of preliminary tests on various papers impregnated with known different proportions of the oils.

In order to determine the curve of gradients for a homogeneous dielectric regardless of specific capacity, I plot the necessary curve from the well-known mathematical formula in the case of single or concentric cables, and in the case of irregular shaped or multiple conductor cables, I may calculate it or make a large-sized model section of the cable, and establish a difference of potential which represents the working conditions between the conductor or conductors and sheath. I then lay a sheet of high resistance metal across this section model, and trace out by a null galvanometer method with two needle points the equipotential lines from which the gradient can be easily determined with sufficient approximation. The curve of gradients for homogeneous dielectric, regardless of conductivity, is similar to the above.

In the case of stranded conductors a smooth homogeneous surface should first be obtained by filling up the interstices between the strands with lead or other conducting material.

The claims are:—

1. A cable in which the coats of material are arranged in such a manner that the disruptive stress in every part of the dielectric is approximately uniform.

2. Rendering the stress more uniform by changing the conductivity of the material of each coat without appreciably diminishing its specific disruptive strength.

3. Rendering the stress more uniform by changing the specific capacity of the material of each coat without appreciably diminishing its specific disruptive strength.

4. Rendering the stress more uniform by altering both the conductivity and the capacity of the coats in a regular manner, depending in each coat upon the stress to which that coat would otherwise be submitted.

5. In the manufacture of a cable reducing the thickness of insulation by rendering the factor of safety uniform in every coat by altering the disruptive strength of each coat so as to be proportional to the stress to which that coat has to be submitted.

6. The improved electric cables substantially as described.

Mr. O'Gorman's Patent, No. 21,170 of 1901, relates to covering the stranded conductor with a lead sheath directly on the copper; the complete specification is as follows:—

The object of this invention is to reduce the thickness of insulation on electric cables, and thereby cheapen the cost of manufacture. In stranded cables as hitherto constructed, the external surface of the conductors of single and multiple cables, and the internal and external surfaces of the outer conductors

Digitized by Google

of concentric cables present in section portions of small curvature, due sometimes to the individual strands which are either small circles or other shapes presenting points, roughnesses or corrugations, and sometimes to joints or splits, kinks or twists in the individual wires themselves. The evil effect of such roughnesses is greatly enhanced by the slight decentralisation of the conductor, which occurs or is caused by an indentation of the outside of the insulation, or of the lead sheath, or when there are several separate conductors in the same cable. According to this invention a smooth homogeneous conducting surface is obtained by filling up or covering over the interstices between the strands of the conductor by a continuous conducting sheath of metal, which may either be in actual electrical contact with the conductor, or it might be very close to, but slightly insulated from, it. There are many ways in which the smooth surface may be obtained, but I prefer to cover the conductor with a continuous and seamless lead sheath by means of an hydraulic press.

The claims are:—

1. Electric cables having stranded conductors the outer surfaces of which conductors are rendered smooth by a covering of lead or other conductor substantially as described.
2. Electric cables having stranded conductors, the outer surfaces of which conductors are rendered smooth by filling up and covering over the interstices by a continuous conducting sheath of metal substantially as described.
3. An electric cable substantially as described.

WINDSOR ESSEX AND LAKE SHORE RAPID RAILWAY

A New Single-phase Distribution System

THE first single-phase electric railway to be put to work in Canada was the Windsor Essex & Lake Shore Rapid Railway, which ran its first car in September last. The line is of particular interest on account of the use of three-wire single-phase generators for supplying current to both a 6,600-volt trolley circuit and a one-wire 13,200-volt transmission line. A description of the equipment is given in the *Electric Railway Review* (Chicago).

The northern terminus of the road is Windsor, Ont., across the river from Detroit. From Windsor the line takes a southeasterly direction as far as Kingsville, a distance of some 28 miles. Further extensions are in progress.

The roadbed is built on the public highways in the towns and either at the side of a highway or on a private right of way parallel with it for the intervening distances. The track is laid with 80-pound T-rails with continuous joints, and is well ballasted with broken stone and gravel. The rail joints are electrically connected with No. 000 bonds soldered to the ball of the rail outside of towns and to the web under the fishplates in streets. Cross bonds are installed five to the mile.

A specially substantial type of overhead construction has been installed throughout the entire route, and it is interesting to note that the 6,600 volts pressure is carried on the trolley even in the towns.

The working conductor is a No. 000 grooved copper wire. It is supported by hangers spaced 10 ft. apart along a $\frac{7}{16}$-inch steel strand single cable forming the messenger. Outside of towns the messenger is hung from rod-supported angle iron brackets, and within towns the catenary cable is supported by spans of $\frac{5}{16}$-inch stranded steel cable with wood and porcelain insulators. The line is head guyed at intervals of 1,100 ft.

At Windsor a 500-volt trolley line of the Detroit United Railway system is intersected, and a special piece of overhead construction was required to prevent any possibility of the electrical crossing of the two overhead conductors, one at 6,600 volts and the other at 500 volts. As the 500-volt line was in operation before the 6,600-volt trolley was built, it became necessary for the builders of the new line to take the necessary precautions to prevent trouble. A complete separation of the circuits was made by installing about 25 ft. on either side of the 500-volt line intersecting a long wood break trolley insulator placed in the 6,600-volt trolley. This provides a dead section of catenary supported trolley for a safe distance on either side of the intersecting 500-volt trolley, which is crossed with an ordinary 90-degree trolley pan insulated for 500 volts. The length of the dead section in the 6,600-volt trolley is sufficient to assure that should a trolley pole leave the 500 volt wire it will not be able to swing far enough to make a connection with the high-pressure trolley. The dead section in the 6,600-volt trolley also requires that the single-phase cars drift across this intersection. The continuity of the 6,600-volt circuit on either side of the dead section is made complete by a jumper carried on high-tension line insulators and protected by grounded guard wires.

Thirty-foot wooden poles are used for all construction except that in the streets of Windsor. These poles are set in earth and are reinforced near the surface of the ground with a 4 ft. by 2 by 12 in. breast block.

Where span construction is used in the streets of Windsor the span wires are supported by concrete poles supplied by the Concrete Pole Company, St. Catherines, Ont. These poles are of two sizes, designed for 1,000 and 3,000 pounds strain. Both types of poles are rectangular in section. The smaller pole is 10 in. square at the butt and 6 in. square at the top, reinforced with four $\frac{7}{8}$-in. round steel rods placed within the four corners. The 3,000-pound pole is 16 in. square at the butt, 10 in. square at the top, and is similarly reinforced with four 1-in. round steel rods.

It is not necessary to describe the power-house in great detail. There are two generating sets, each driven by a 750 h.p. horizontal steam engine. Each of these engines has mounted on its shaft the field of a 500-kilowatt 25-cycle single-phase three-wire flywheel type generator, built by the Canadian Westinghouse Company, Limited. The windings of these generators are such that from the terminals may be obtained current at 13,200 volts pressure and at 6,600 volts pressure. The two windings may be used in series for obtaining these two voltages, or may be connected in parallel for obtaining the full capacity of the machine at 6,600 volts. One of the three terminals of each machine is earthed. Belt-driven exciters are employed, and the voltage is kept constant by a Tirrill regulator. The two three-wire generators feed each of two bus-bars, one carrying current at 13,200 volts and the other at 6,600 volts. The bar of the lower potential feeds direct to the trolley wire, while the one of higher potential feeds a single-wire transmission line serving

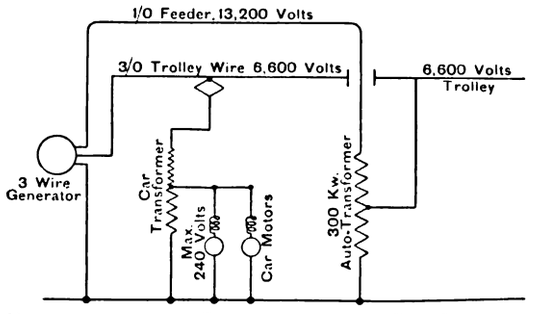

DIAGRAM SHOWING TRANSMISSION AND CAR CIRCUITS.

an auto-transformer substation at Maidstone, 18 miles from the power station.

The method of feeding the 6,600-volt trolley is of particular interest, inasmuch as there is used an auto-transformer substation requiring only a single wire for the transmission line. The trolley wire between Windsor and the Kingsville power station is divided into two sections. An 18-mile section from the power house to Maidstone is fed direct from the 6,600-volt bus of the three-wire generators in the power station. The section between Maidstone and Windsor, about 12 miles, is independent of the power-house section, and is fed by a transmission line carried at the tops of the poles along the right of way. This transmission line comprises a single No. 0 wire of hard-drawn copper supported on three-piece 40,000-volt insulators supplied by the Lima Insulator Company. The working pressure of the line is 13,200 volts. This single high-tension wire feeds a 300-kilowatt auto-transformer, which, in turn, feeds the Windsor section of the trolley wire at 6,600 volts.

The accompanying sketch shows diagrammatically how simple is the transmission and feeding system of this single-phase railway. The auto-transformer at Maidstone is installed in a concrete building 12 by 12 by 14 ft. in dimensions. The circuit-breaker and switch for handling the current fed through this transformer are located at the origin of the transmission line in the power station. Lightning protection and hand-operated disconnecting switches complete the substation equipment.

The rolling stock equipment includes five new three-compartment passenger cars equipped with motors, and four trailers and two express cars which are being rebuilt from trailer cars formerly operated on the New York City elevated lines. Each car is equipped with two Westinghouse No. 132 single-phase motors rated at 100 h.p. each. The control equipment includes an auto-transformer supported from beneath the car sills by 4 by 4 by $\frac{3}{8}$ in. angles. As the cars are double-ended two drum controllers are used to vary the voltage of the current fed through the auto-transformer to the motors. Multiple unit control is not adopted. The pantagraph trolleys collect current at 6,600 volts pressure, which is fed to the motors at a maximum pressure of 240 volts.

A 1,500-VOLT CONTINUOUS-CURRENT RAILWAY IN THE MISOXER VALLEY

THIS railway connects the town of Bellinzona, in the Canton of Tessin, with Mesocco, in the Canton of Graubünden, and follows the course of the River Moesa, in the Misoxer Valley. The Moesa rises in the St. Bernard Alps, and joins the Ticino, which flows into Lake Maggiore. The power station for supplying the railway is situated at Cebbia, just above Mesocco, where the Moesa has a fall of 300 metres, and a minimum water supply of some 500 litres per second. The following description of the railway, which has only recently been equipped electrically, is abstracted from a recent article in *Elektrotechnik und Maschinenbau* (Vienna).

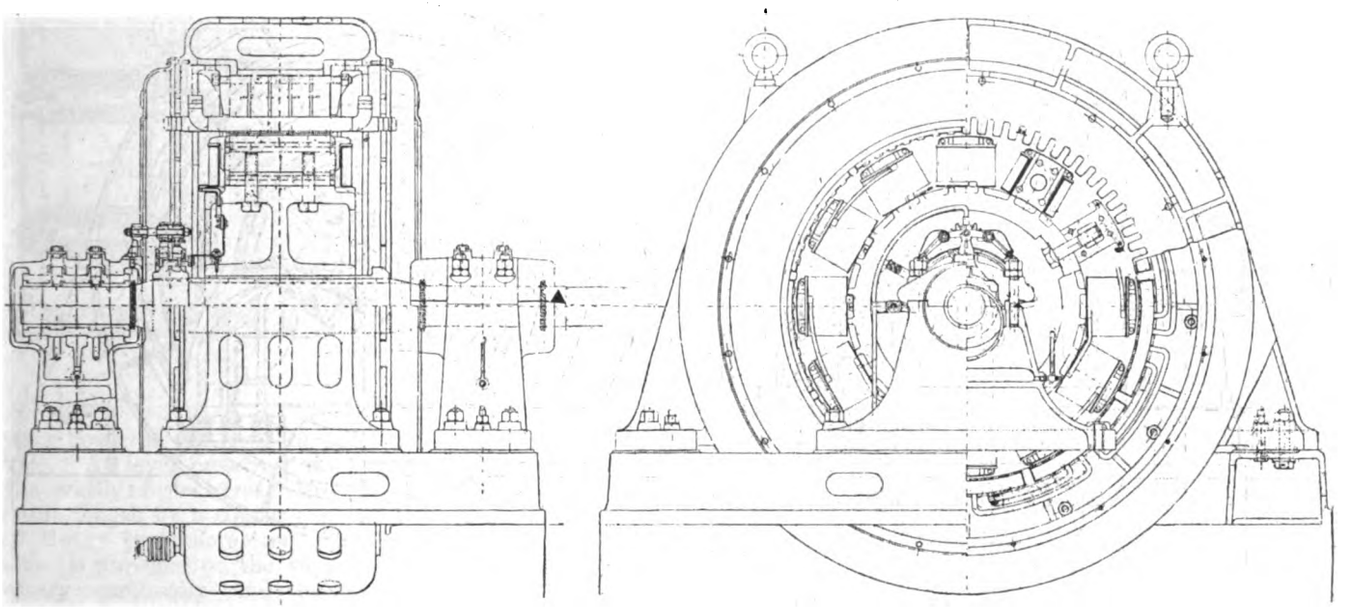

FIG. 1.—420 KW. THREE-PHASE GENERATOR.

The line is 31 kilometres in length, and rises from an altitude of 6 metres above sea-level at Bellinzona to 769 metres at Mesocco. The ascent from Bellinzona to Mesocco is continuous, and the gradients are heavy, rising to a maximum of 6·6 per cent. The 50-ton trains are to be hauled up this gradient at a speed of 19·5 km. per hour.

At Cebbia, where the generating station is situated, a dam has been built across the river, and the water flows through a canal to a reservoir, from which it is admitted to a pipe line, 1,660 metres long, constructed of cast-iron pipe of 500 mm. internal diameter. This pipe line is divided into six sections or zones of increasing thicknesses to correspond with the increasing pressure. Thus the six thicknesses of the pipe are 12, 14, 17, 20, and 28 mm., corresponding to the six average pressures of 5, 10, 15, 20, 25, and 30 atmospheres. The joints in the last two zones are protected with cast-iron rings screwed over the joints to prevent the lead caulking from being forced out.

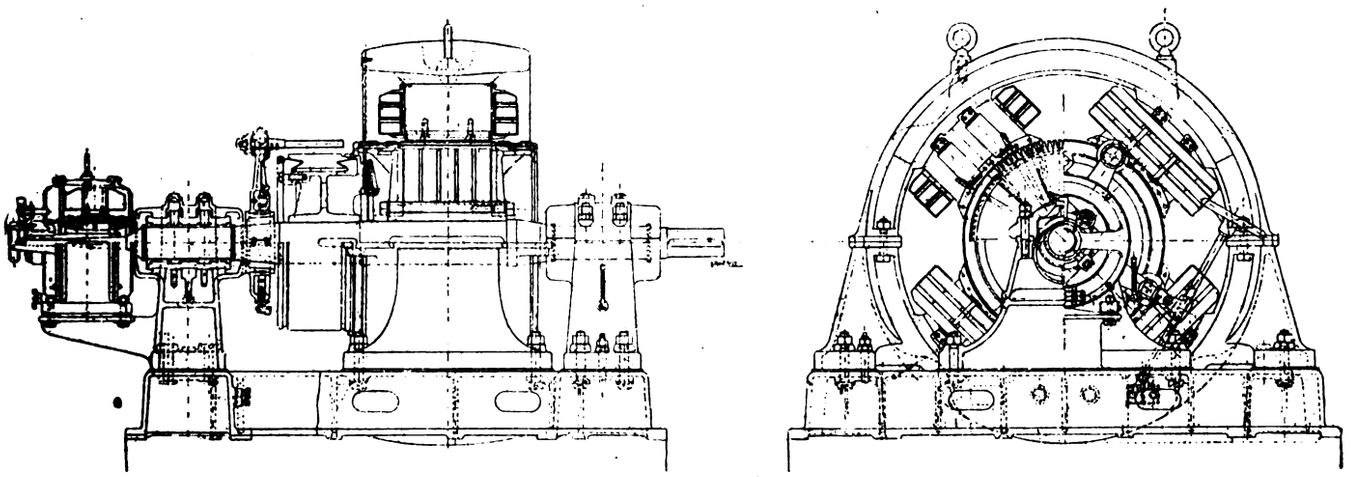

FIG. 2.—275 KW. CONTINUOUS-CURRENT GENERATOR.

There are at present in the power station two 1,000-h.p. water turbines, each of which is coupled direct to a three-phase generator on the one side, and a continuous-current generator on the other side. Between each generator and the turbine there is a flywheel and a flexible coupling. The speed of each set is 500 revs. per min. The three-phase generator has a capacity of

Digitized by Google

420 kw., and generates at 10,000 volts and 50 cycles (Fig. 1). The continuous-current generator has a capacity of 275 kw., and generates at 1,600 volts (Fig. 2). A 13-kw., 70-volt. exciter is directly connected to the continuous-current generator. Continuous current is supplied direct to the contact wire at Mesocco, and the high-tension alternating current is transmitted to the substation at Roveredo, where it is transformed by means of motor generators into continuous current at 1,550 volts.

The six wires (two three-phase circuits) are each 4·5 mm. in diameter, and supported, on porcelain insulators, with iron pins (Fig. 4) at a distance of 600 mm. from one another.

Wooden poles are used in all cases. They are painted but not impregnated.

The continuous current for the overhead wire at Mesocco is transmitted from the power house at Cebbia, 1·3 km. distant, through two feeder cables, each of 100 sq. mm. section.

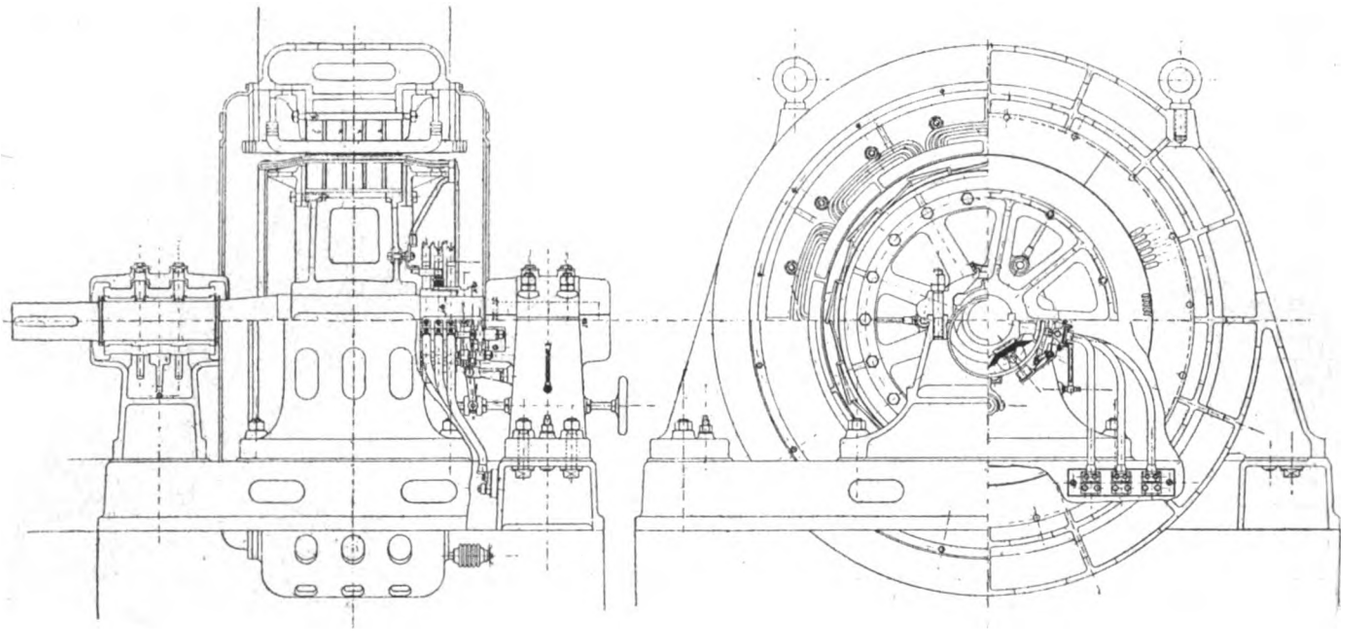

FIG. 3.—400 H.P. THREE-PHASE ASYNCHRONOUS MOTOR.

The substation at Roveredo contains two motor-generator sets, each of which consists of a 400-h.p., 9,000-volt, 490-r.p.m., 50 cycle asynchronous motor (Fig. 3), and a 275-kw., 1,500-volt continuous-current

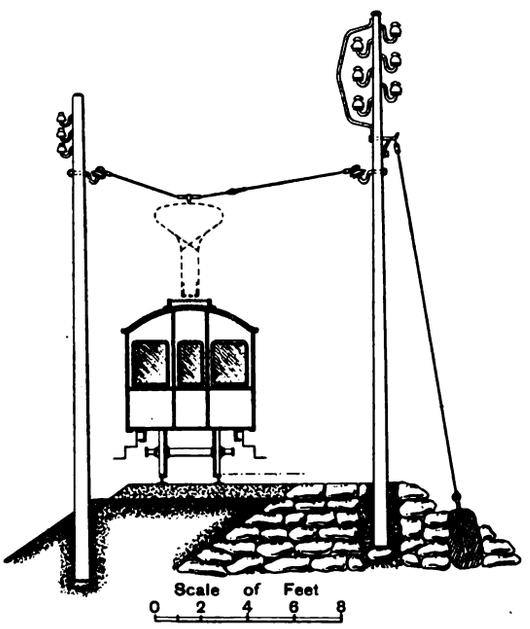

FIG. 4.—OVERHEAD EQUIPMENT.

generator. The machines in both power station and substation, as well as the car motors, were supplied by the Oerlikon Co.

The high-tension transmission line is 22·3 km. long.

The overhead wire is supported 5·5 metres above the rails over most of the route, but in the stations and at level crossing it is supported at a height of 6 metres above the rails, and in tunnels and under bridges the height is 4·3 metres. The wire is insulated from the cross-wires, and the cross-wires are fixed to the poles with insulators of the form shown in Fig. 5. The contact wire is of hard-drawn copper, 9·5 mm. in diameter. The cross-wires are of steel, 5 mm. in diameter.

The rails, which have a cross section of 100 sq. mm., are used as the return conductor. The lengths are electrically connected with flexible copper bonds. Cross connections from rail to rail are provided every 120 metres.

The contact wire is divided into six sections, which can be insulated from one another when necessary.

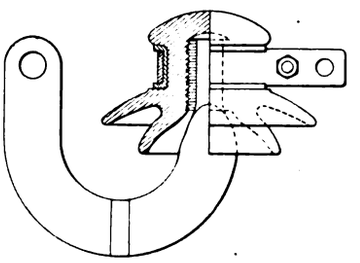

FIG. 5.—INSULATOR. SCALE, ONE-FIFTH FULL SIZE.

Between any two sections is a short piece of contact wire, which, ordinarily, is electrically connected with both adjacent sections, and, consequently, when passing over the section insulator, the current is not broken. When the two sections are insulated from one another, and only one is alive, the intervening insulated piece

Digitized by Google

of contact wire is dead, and this prevents the dead section from being made alive through the two collector bows, as the bows cannot touch both sections at once. At level crossings the contact wire is dead for the width of the street, the current being carried over this length by a copper cable of 100 sq. mm. section. Every two kilometres, lightning protection apparatus is provided on the supporting poles, with the necessary earth-wire and buried earth-plate. The poles are spaced normally 30 metres apart, but at sharp curves this distance is reduced to 16 metres. The telephone wires, which are at 3 mm. diameter galvanised iron wire, are crossed every 300 to 500 metres.

The motor-cars were supplied by Ringhoffer, of Prague. The length of the car body is 14·1 metres, and the width is 2·65 metres. The car is divided into two compartments, II. and III. class; there is seating

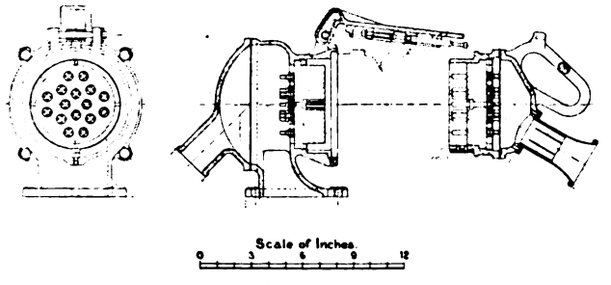

FIG. 7.—COUPLING TOE CONTROL CONNECTIONS.

room for 12 in the second class, and for 39 in the third class, making a total seating capacity of 51.

The cars are provided with Böcker air brakes.

Each motor-car has four motors, one on each axle. Each motor is rated at 66 h.p., 750 volt, two being permanently connected in series. The motors are geared, the gear ratio being 1 : 4·5. One motor-car containing four such motors can haul a 53-ton train (including the motor-car) at a speed of 38 km. per hour on the level, or at a speed of 19·8 km. per hour up a gradient of 6·6 per cent. The efficiency of the motors at rated load is 85 per cent.

The electric control system is the same as that used on the Cologne-Bonn railway, and developed by the Siemens-Schuckert Co. The control connections run through the whole length of the train, and the cars are connected by means of the coupling shown in Fig. 7.

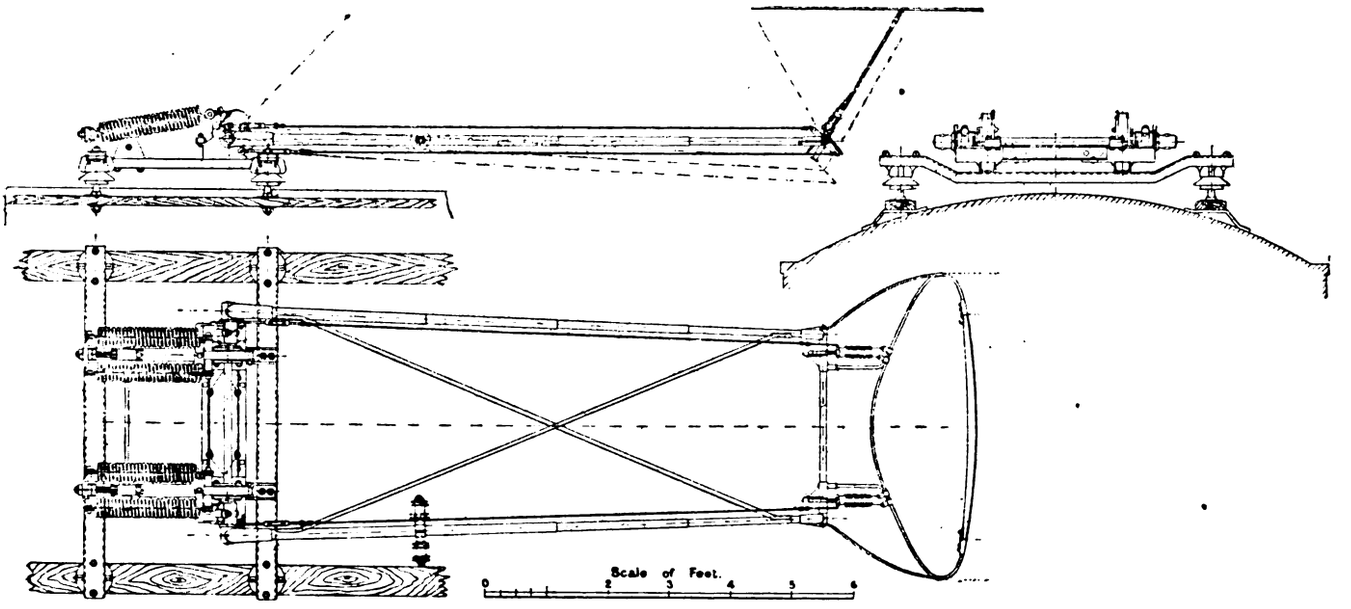

FIG. 6.—COLLECTOR BOW.

Each motor-car has two collector bows, as illustrated in Fig. 6 above.

Manitoba Telephone Purchase.—The Manitoba Government has purchased the undertaking of the Bell Telephone Co. in Manitoba for the sum of £666,000. The transfer takes place on January 15th. The Manitoba Government will issue 4 per cent. Government bonds at 40 years, payable at par.

Recent Electric Power Contracts.—We have received from the British Thomson-Houston Co., Ltd., particulars of some important contracts for power plant which they have in hand. One of these is for a 500 h.p. 500 volts 50-cycle 3-phase motor, running at 1,450 r.p.m., for the Mold Collieries, to be direct connected to a turbine pump, which will operate against a head of approximately 600 feet. In the same pump-house will also be erected two 275 h.p. motors, direct connected to slow-speed pumps running at 180 r.p.m. Another colliery equipment, the contract for which has been placed with the British Thomson-Houston Co., is that for the Moss Hall Coal Co., which includes the complete electrical equipment of this company's Maypole and Lowhall pits, including the provision of the necessary equipment for a new generating station, which comprises two 350 kw. steam-driven generators, with the necessary switchboard, the whole of the cable work for the same, and a small lighting set of 40 kw. capacity. The equipment of the Maypole Pits includes four sets of electrically-driven pumps, complete with the necessary switchgear, and the whole of the cable work, both on the surface and underground, together with all the overhead transmission line. The primary voltage is 3,000 volts, and the current, 3-phase 50 cycles. The equipment of the Lowhall Pit, which will be operated from the same generating station, includes three sets of pumps of the horizontal 3-throw type of large capacity, to which will be coupled three 135 h.p. motors, and three sets of haulage gear, together with the complete cable equipment, both surface and underground. Another important contract which we understand has been placed with the B.T.H. Co. during this past year is the electrical equipment of a Reversible Cogging Mill for Messrs. Dorman, Long & Co., Ltd., of Middlesbrough. This is said to be the first electrical equipment of this nature that has been placed with a British firm. It involves the supply of very heavy electrical machinery, including the main mill motor, which has a continuous capacity of 1,200 h.p. and a maximum torque capacity up to 3,600 h.p., developing these powers at a speed of 70 r.p.m. Another important development in the application of electrical power for industrial purposes is the advance that has been made in connection with the electrical operation of textile mills. The British Thomson-Houston Co. has now installed upwards of 10,000 h.p. in motors in textile mills in the United Kingdom, and are at present engaged in the electrical equipment of a large mill in the Manchester district which involves the installation of upwards of 75 motors, varying in capacity from 7½ h.p. to 170 h.p. each.

THE BIRMINGHAM TRAMWAY ACCIDENT

LIEUT.-COL. H. A. YORKE has reported upon the accident that occurred on the Birmingham Corporation Tramways on October 1st (ELECTRICAL ENGINEERING, Vol. II., pp. 547 and 567). In this case, as tramcar No. 22 was descending the incline in Warstone Lane, the driver (Inspector Hall) lost control of it, with the result tht it ran away down the incline, and was overturned at the corner of Warstone Lane and Icknield Street, striking an overhead standard as it fell. Two passengers died from injuries received, and twelve were injured more or less seriously. The car was a four-wheeled, double-decked car, fitted with the hand brake, electric rheostatic brake, and the magnetic track brake, and also with four sanders, namely, two at each end, and a lifeguard of the trigger type. The total length of the car was 27 ft. 6 in., the wheel base being 6 ft. The gauge of the tramway is 3 ft. 6 in. At the time of the accident there were about 16 passengers on the car, half of whom were inside and the other half on the top. The passengers who received the fatal or serious injuries were those on the top of the car.

Warstone Lane is about a quarter of a mile long, the gradients in it being as follows, commencing from the top of the hill :—1 in 143·8, 1 in 22·7, 1 in 17, 1 in 19·7, and 1 in 36·6. The car in question left the depôt at 4.59 a.m., in charge of motorman J. E. Mountford, who on his second journey met Inspector Hall at Edmund Street, and informed him that there was something wrong with the magnetic brake at "No 2" end of the car. The car left Edmund Street for the third trip to Foundry Road at 6.29 a.m., with Inspector Hall in charge of the car, and motorman Mountford standing alongside of him. Inspector Hall seems to have tried the magnetic brake when going down the incline in Summer Row, with the result that on the first, second, and third notches it did not act properly, but brought the car up with a jerk when the handle was moved to the fourth notch. When he reached the incline in Warstone Lane he again tried the magnetic brake, which on this occasion seems to have completely failed on all notches. He then moved the handle to the "on" position, and tried the brake a second time, but still without effect. He then tried to stop the car by reversing the handle from the forward to the back position and moving the controller handle to the sixth notch of power, but still without effect. By this time he was more than half-way down the hill, and had entirely lost control of the car. He then applied his hand brake for the first time, to the fullest possible extent, but the speed of the car was such that the hand brake had little or no effect in checking it. On reaching the curve at the bottom of Warstone Lane hill the wheels skidded, and almost immediately afterwards the car turned over to the outside of the curve and fell on its side, striking a trolley wire standard in its fall, the passengers on the top being thrown on to the pavement and one of them crushed between the standard and the car.

The immediate cause of the disaster was the action of Inspector Hall in taking the car down Warstone Lane with a defective magnetic track brake, and experimenting with that brake on the incline. Had he applied the hand brake before starting down the incline, no accident would have occurred, as the gradients are such that the car might well have been controlled by means of the hand brake only, the only precaution necessary being that the hand brake should be applied at the commencement of the hill, so that the speed of the car should be checked from the outset. That this is the case is proved by the fact that the car had already been taken down the hill that morning by means of the hand brake only. Inspector Hall seems, however, to have selected this hill for the purpose of testing the magnetic brake, and did not attempt to apply the hand brake until the speed of the car was far beyond its control.

The failure of the magnetic track brake to act on this occasion, the report states, is said to have been due to a broken grid in the fourth resistance box on the car. According to a statement made by Mr. C. W. Hill, Electrical Engineer of the Corporation Tramways, the controller at "No. 2" end of the car, and the insulation of the cabling and wiring of the car, after the accident was found to be in good order, and the only defect that could be discovered was the broken grid. The resistance boxes, of which there are five, are in use both for propelling and braking purposes, and it might be thought that such a fracture would be discoverable, not only when the magnetic brake was in use, but also when current was being supplied from the trolley wire for the purpose of starting the car. Mr. Hill put forward the theory that the electrical pressure of the current for driving purposes would be sufficiently great to bridge the gap formed by the fracture, whereas, in the initial stages of braking, current generated by the motors acting as generators would have a low pressure, and would not be able to overcome the interruption in the circuit. Experiments made by Mr. A. P. Trotter, the Electrical Adviser to the Board of Trade, at 8 Richmond Terrace, however, says Lieut.-Col. Yorke, hardly support this theory, as it was found that a current of 10 amperes, which is probably less than the usual current passing when cars are starting from rest, is sufficient to cause fusing to take place between the two opposing ends of the fracture and between the sides of the broken and adjacent members of the grid. No such signs of fusing were, however, discernible in this case. It was, therefore, impossible to say whether the above explanation of the failure of the magnetic track brake is the correct one or not.

CATALOGUES AND PAMPHLETS RECEIVED

FEED WATER HEATERS.—A new edition of a pamphlet describing the "Wilkinson" line steam feed water heater is to hand. This apparatus, the object of which is to obtain economies by ensuring that the temperature of the feed shall approximate as nearly as possible to that of the steam in the boiler, was described in some detail in ELECTRICAL ENGINEERING, Vol. II., page 301, and some further results of tests were given on page 623 of the same volume. A statement as to the change of agency for the apparatus appears under "Miscellaneous Business Notes." Inquiries are facilitated by the convenient blank inquiry form contained in the pamphlet.

FLAME ARC LAMPS.—A new catalogue from Messrs. Crompton & Co., Ltd., deals with the Crompton-Blondel system of flame arc lighting with continuous currents. The construction of the Crompton-Blondel lamp and the particularly advantageous distribution of light obtained therefrom were fully dealt with in ELECTRICAL ENGINEERING, Vol. II., page 853, and the specification of the Blondel patent was given in Vol. I., page 521.

INCANDESCENT LAMPS.—A card printed by the three-colour process from the British Thomson-Houston Co. contains a reproduction of a painting entitled "Sunset in the Fens," with a suggestion that when the sun has set, B. T.-H. Edison lamps should be used.

OSRAM LAMPS.—Messrs. Pooley & Austin have issued a pamphlet putting forth the advantages of the Osram lamp, and giving figures as to the economy in current to be obtained as compared with carbon filament lamps of equal candle-power.

ROLLER BEARINGS.—The revised catalogue of the Empire Roller Bearings Co., Ltd., points out the advantages claimed for well designed roller bearings over plain bearings, and gives a general description of the Empire patent roller bearing axle boxes for railway and tramway vehicles, giving results of tests showing the reduction both of starting and running friction obtained by their use. Special forms of bearing for trucks, colliery tubs, &c., are described, as well as a standard swivel pattern for shafting. Empire Roller Bearings are also applied to road waggons, lifts, ventilating fans, rolling mills, agricultural machinery, harbour dredgers, and other purposes, where an accurately aligned load can be secured under ordinary conditions of work.

WIRES AND CABLES.—The Western Electric Co. have issued a new abridged price list, arranged in a convenient form, of vulcanised electric light wires and cables, twin circular conductors, twin vulcanised flexible cords, and electrolier wire, all in accordance with the standards of the Cable Makers' Association.

The Burbacher Hütte Iron & Steel Works.—In Figure 8 of this article, published in our last issue, the letters V and A have been transposed by a draughtsman's error. The voltmeter is naturally connected across the circuit, and the ammeter in series with it.

Runaway Tramcar Accident at Glasgow.—A fatal runaway tramcar accident occurred at about 5 p.m. on Friday evening upon the Glasgow Corporation tramway system. It took place upon the incline known as the Bell of the Brae, between Cathedral Square and Duke Street, upon the Springbrow-Mount Florida route. The weather was frosty and foggy at the time, and through some at present unknown reason, a car became unmanageable, and dashed down the hill. The first obstacle to the runaway car was a horse-drawn goods lorry, belonging to the Glasgow & South Western Railway Co. This was smashed, and swept out of the way, and the car, continuing its runaway journey soon dashed into another lorry belonging to the same company, whilst further on yet another lorry, unable to get clear of the track, was smashed and the horse killed. This latter collision pitched the driver of the tramcar out into the roadway, and also smashed a sectional pillar box on the pavement. Two other lorries were subsequently damaged by collision, but as the car reached more level ground, it naturally slackened speed considerably, and was brought to a standstill by the conductor applying the brakes. Unfortunately the accident has resulted in two deaths, for the driver of the car who was thrown into the road, and a van-boy who was on one of the lorries which were smashed, have both succumbed to their injuries. A number of the passengers, who numbered between 30 and 40, were slightly injured, but the comparative immunity from injury to these appears to have been due, first, to the fact that the car kept to the rails, and secondly, because the conductor locked the doors of the car and refused to allow any of the passengers to jump off, which must have saved many serious injuries. In all, eight persons were injured, and three have been detained in hospital.

VERTICAL SHAFT ROTARY CONVERTERS

ON page 23 of ELECTRICAL ENGINEERING for January 2nd we gave a short note relating to a large vertical shaft rotary converter recently installed in a sub-station in Chicago, and we are now able to supplement this description by some illustrations showing the arrangement of the machine and some additional particulars which have appeared in the *Electrical World* (New York). The machine in question was installed by the Commonwealth Edison Company, of Chicago, in its Market Street sub-station, and is the first vertical shaft rotary converter to be put in operation in an American central station.

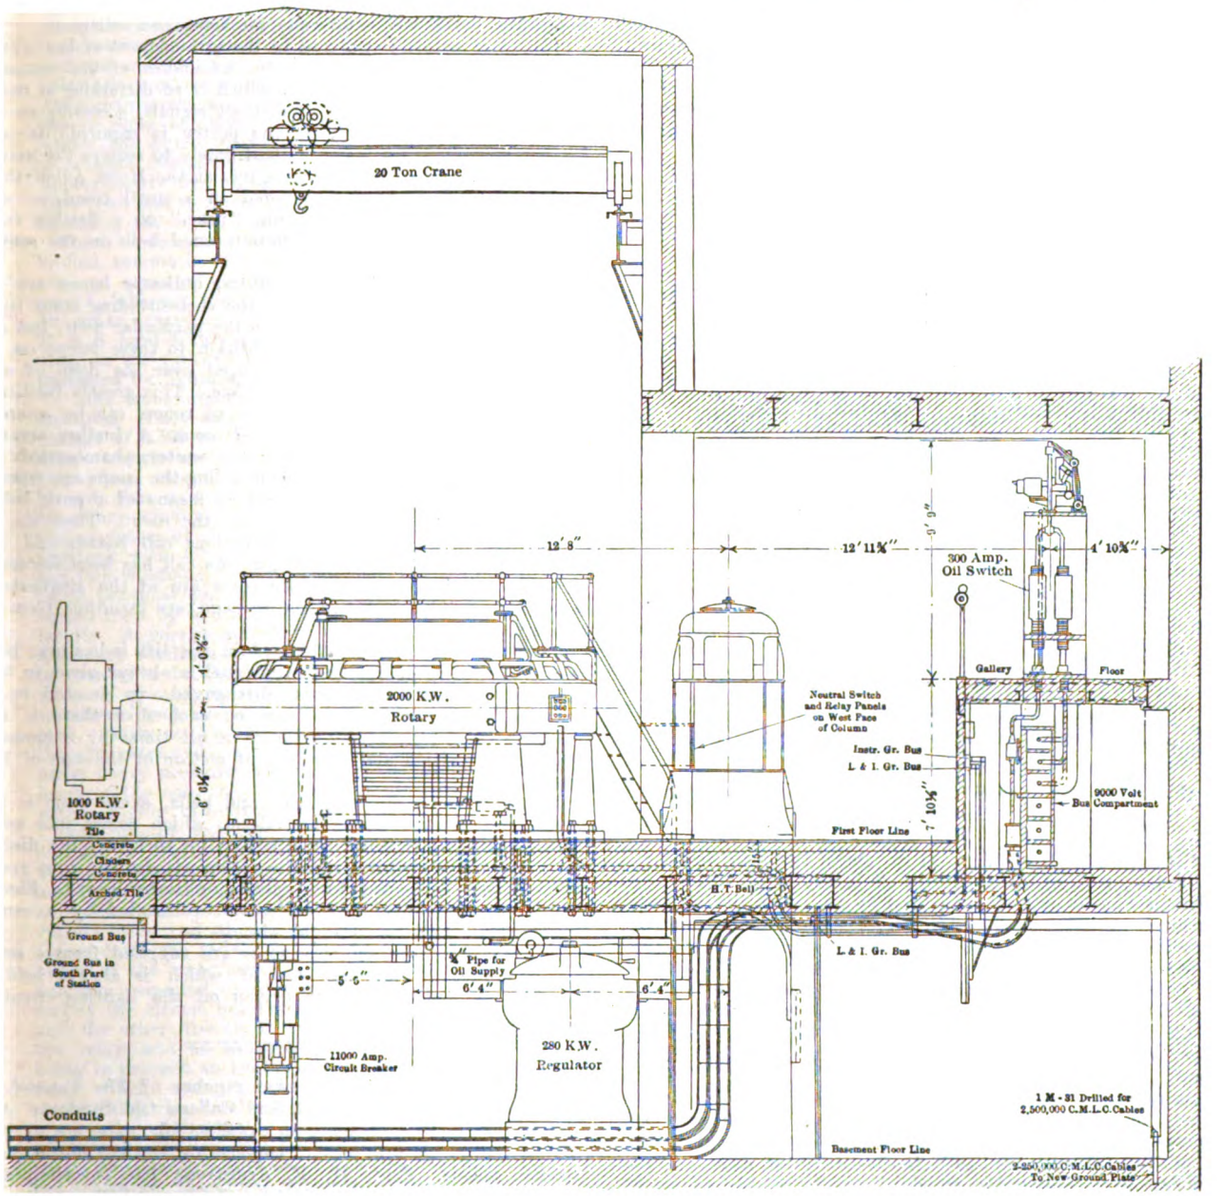

FIG. 1.—SECTIONAL ELEVATION OF SUBSTATION, SHOWING ARRANGEMENT OF VERTICAL SHAFT ROTARY CONVERTER AND SWITCHGEAR.

The same company has already in use five 2,000-kw. vertical shaft motor-generator frequency changers, which are very satisfactory. The frequency changers have step bearings similar in principle to those on the Curtis steam turbine; the weight of the bearing being carried on a film of oil or water forced under the bearing. The rotary converter under consideration, however, differs considerably in construction from the frequency changer sets. As already stated, it is a 2,000-kw. General Electric machine running at a speed of 166 r.p.m. Provision is made for carrying the weight of the revolving armature either on a roller bearing or on an oil pressure bearing. The roller bearing has given good results in factory test runs, and it is confidently expected that it will be the form of bearing finally adopted. To provide for operation, should changes be necessary during the perfecting of the roller bearing, however, an oil bearing, interchangeable with the roller bearing, has been provided, together with a set of pumps for maintaining the pressure in the oil bearing. Fig. 2 is a vertical sectional drawing showing the relation of parts. The armature of the machine revolves about a stationary central shaft or pivot, 23 in. in diameter, which carries on its upper end the interchangeable roller or oil pressure bearing. The armature is mounted on a sleeve which revolves outside of the stationary shaft. The weight of this sleeve and the armature which it carries is taken by the bearing at the upper end. To get at the roller bearing, it is only necessary to remove a steel cap from the upper end of the revolving sleeve, after having first relieved this steel cap of the weight of the armature and sleeve by means of screw-jacks. These screw-jacks, which are a permanent part of the machine, consist simply of a set of screws which are accessible from the basement below the machine.

The field magnet structure, carrying 18 poles, is supported on cast-iron pillars resting on a concrete base ring. To keep the revolving armature in line, there are two guide bearings, each 14 in. long, below the roller bearing. To change from roller bearing to oil pressure bearing, it is a simple matter to take

Digitized by Google

the weight off the top bearing, withdraw the cap screws holding the top plate and change from a roller to oil pressure bearing or *vice versa*.

The advantages of the vertical shaft rotary converter are many. There is a saving of about 17 per cent. of weight in the vertical shaft machines, as compared with the horizontal shaft machines this company has in service. The horizontal shaft machines, to be sure, run at a lower speed, but they have been the only one available, so that leaving out of account the questionable possibility of building satisfactory higher speed horizontal shaft machines, there is an important reduction in weight by the vertical shaft construction. One of the most important advantages of this construction is the accessibility of the brushes. The brushes on the vertical shaft machine are readily accessible to an attendant on a platform extending around the machine and resting just above the field poles. On a horizontal shaft machine the attendant must climb ladders in difficult positions. The weight of the vertical shaft, 2,000-kw. machine is stated to be about 67 tons. The diameter of the circular floor space occupied by it is 15 ft. 3 in. The height above the floor is 9 ft. 3 in. The 2,000-kw. horizontal shaft machines of the company occupy a floor space of 16 ft. 6 in. ×

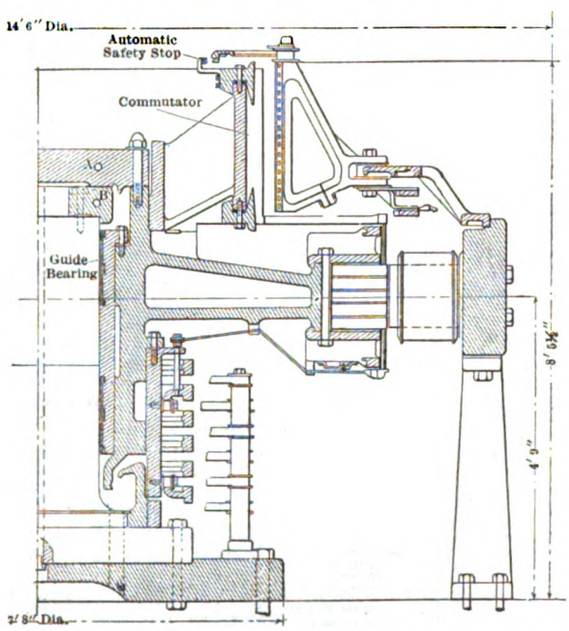

FIG. 2.—SECTION OF PART OF 2,000-KW. VERTICAL SHAFT ROTARY CONVERTER.

16 ft. 6in., and extend 12 ft. 11 in. above the floor and 3 ft. 7 in. below, making the total over all height 16 ft. 6in.

The machine is entirely supported by the steel and concrete floor of the building as shown in Fig. 1. The electrical apparatus in the basement consists of a 250-kw. induction regulator for the alternating current end, and two single-pole 11,000 ampere solenoid-operated circuit-breakers in the direct current leads. The 300 ampere oil switch shown on the right control the alternating current side as a complete unit, as there is no further switch on the low tension side of the step down transformer.

This rotary converter gives direct current at from 240 to 300 volts. The neutral of the low tension side of the transformer is connected to ground and to the neutral of the direct-current system, thus doing away with the necessity of direct-current balancing sets. This is the standard practice of the Commonwealth Edison Company. The rotary converter is the latest addition to a sub-station which already has four 1,000-kw. horizontal shaft rotary converters. An interesting economic feature of this sub-station is the use of a transformer giving an increased voltage for one of the rotary converters in order that the direct-current voltage delivered may be high enough to charge the batteries. The transformer connections allow the converter to be worked at 300 to 360 volts instead of 240 to 300 volts. This arrangement is claimed to present considerable advantage over the use of a separate booster for battery-charging.

Institution of Electrical Engineers: Students' Section.—A visit has been arranged to the works of the India Rubber, Gutta Percha, and Telegraph Works Ct., Ltd., on February 15th, at 10 a.m., and students wishing to join the party should send in their names at once to the hon. sec., Mr. W. B. Thompson.

A HOTEL TELEPHONE AND SIGNAL EQUIPMENT

SOME notes are given in the *Elektrotechnische Zeitschrift* on the very complete installation of electric bells, telephones, and clocks at the Hotel Adlon, Unter den Linden, Berlin, which presents several points of interest.

The telephone system consists of a switchboard with the operator's positions worked on the central battery system, equipped with lamp calling signals and double ring-off signals. This board serves as a local exchange for the 400 telephone stations in the various rooms of the hotel, and also is connected by eighty junction lines to the exchanges of the Berlin telephone system. Every room is provided with a telephone, which can be used not only for internal communication, but also to speak with the outside telephone system. Separate telephones are also installed, apart from the main switchboard, for use in connection with the restaurant, kitchens, and cellars.

The chief points considered in the arrangement of the system of bells from the rooms were the avoidance of the continual ringing of bells in the passages, which is so disturbing in many hotels, and the facilitating of distinct signals, according as the waiter, the chambermaid, or the porter is required. It was formerly usual in most Continental hotels to require the visitor to ring one, two, or three times, but at the Hotel Adlon three separate push-buttons are provided on a small board, as well as another set on a neatly made "pear" on a flexible cord. These pushes control three different-toned bells in the service rooms.

Instead of the ordinary indicators, indicator lamps are employed, and when a bell is rung the corresponding lamp lights up not only in the service room on the particular floor, but also in a central control office. In addition to these lamps on the call boards, there is a lamp arranged over the door of each room, which lights up at the same time. This greatly facilitates rapid service, as a greater number of rooms can be attended to without returning to the service room. A further arrangement of lamps indicates whether the waiter, chambermaid, or porter is required. The relays controlling the lamps are released by the servant answering the call by means of a push button in the passage close to the door of the room. Thus the extinguishing of the lamps on the various call boards and over the door of the room indicates that the call has been answered. The three bells in each service room are of the single-stroke type, and, not being out in the passage, are inaudible from the visitors' rooms.

Lamp signals are also employed in the lift indicators; there are two main lifts, and the call signal is always given in both at once, so that whichever is disengaged can proceed to the required floor. At the lift door on each floor there is also placed a lamp board, which shows at all times by a luminous signal the position and direction of motion of the cars of both lifts.

In addition to the telephones and bells, every room is provided with an automatic fire alarm, which comes into action at a certain temperature. The wiring for these is quite distinct from the other circuits, and the rooms are divided into groups of ten, and connected to a central indicator board. Electric clocks are provided in every room, controlled by a central standard clock through eight circuits.

The whole of the signal services are supplied from a set of six accumulator batteries, one of which is always held in reserve. A motor generator driven off the lighting circuit is used for charging.

"The Central."—The December number of *The Central*, the magazine of the Central Technical College Old Students' Association, has as a frontispiece an excellent photogravure of Prof. W. E. Dalby, the professor of engineering at the College, in his sterner moods. Prof. H. E. Armstrong has contributed an interesting article on "The Nature of Chemical Change," which shows what important research work has been done in the Chemical Department of the College; there is a description by Mr. T. H. Mann of the new work on the Cardiff Railway, several books are reviewed, and Mr. E. W. Lewis has written an instructive article on india-rubber, "From Tree to Tyre." The number also contains a review of the 1906-7 college session, and the usual copious "Old Student Notes." Old students of the College who are not yet members of the Old Students' Association should communicate with Dr. E. Frankland Armstrong, the hon. sec. (98 London Road, Reading), and they are also urged, especially if they have vacant appointments to fill, to make use of the Association's employment agency, of which Mr. R. J. Caldwell, B.Sc., and Mr. R. Whymper (Central Technical College, Exhibition Road, S.W.) are honorary secretaries.

A NEW AUTOMATIC ELECTRIC BLOCK SIGNAL SYSTEM

ONE of the most noteworthy features of the Philadelphia & Western Railroad is the automatic electric block signal system as described in the *Street Railway Journal* This road is a double-track, high-speed, direct-current electric line extending westward, a distance of eleven and one-half miles. The essential features of this system are as follows:—The retention of both rails of each track for the return of the propulsion current; cross-bonding facilities between all rails of both tracks at the ends of all track circuits and between one rail of each track intermediate between the end of said sections, wherever desired; the use of ironless reactance bonds, permitting very long track circuits to be operated with a minimum expenditure of energy; the use of alternating currents only for the track circuits, and the operation of all the devices connected with the system, thus doing away with all batteries and the expense incident to their maintenance.

Single-arm, two-position home signals arranged on the normally clear principle are employed with an overlap. In certain places the signals average about 3,300 ft. apart, and a full block overlap is being employed to permit a two-minute headway. In others, the signal spacing averages one and one-half miles with a uniform overlap of about 3,700 ft., allowing a headway of approximately five minutes. Twenty-five-cycle, single-phase current from transformers in the railway's power plant is used for operating the entire signal system.

Power is delivered to the switchboard through a remote controlled automatic oil switch. Each feeder circuit is equipped with an ammeter and an electrically tripped, hand-operated oil switch, whereby the system may be relieved in case of a cross on either transmission line. The latter consists of two No. 6 B. & S hard-drawn bare copper wires strung on separate cross-arms on the railroad company's high-tension pole line, which is protected by lightning arresters.

"Line transformers" are installed at all signal and overlap locations. They step down directly from the transmission line voltage of 2,300 to the voltages required for the signal system. These transformers are protected on the primary side by cartridge fuses mounted in watertight cast-iron boxes, and so arranged that a fuse can be replaced without danger. The secondary windings are three in number, a 55-volt winding for the operation of the signal motors, lights, and line relays, and provided with a tap for local phases of all polyphase relays; and two windings for supplying energy to the track circuits, taps being provided on these windings so that the voltage can be varied from 2½ to 15, as required for track circuits of different length. A copper shield is placed between the primary and secondary windings and connected to ground, affording protection in case of a breakdown in insulation. All coils are insulated with an oil and moisture resisting compound by the "vacuum treatment" process, in which the coils are heated in an air-tight tank. After a vacuum has been secured and the moisture thereby extracted, insulating compound is forced into the coil under heavy pressure, which causes the liquid to penetrate to the heart of the coil, with the result that every wire is surrounded with a highly insulated covering.

Both rails of each track are made available for the propulsion current by ironless "reactance bonds" connected to the rails. When so connected they form a path of low ohmic resistance and large current capacity for the traction current, and at the same time offer an impedance to the passage of the alternating current from rail to rail, whereby a portion of said current is forced down the rails to operate the track relay. The reactance bonds at the transformer end of the track circuit has a single winding connected directly to the rails. The bond at the other end of the circuit has two windings, one connected to the rails and the other directly to the relay. The winding connected to the relay acts as the secondary of a transformer, its object being to prevent an excessive flow of direct current through the relay which, owing to the low ohmic resistance of the relay, would otherwise result were the relay connected directly to the track rails. Attention is called to the fact that these bonds are of the ironless type, and hence are not subject to saturation due to an unbalanced condition of the traction current in the rails, the reactance, therefore, remaining constant under all such conditions. It is also to be noted that alternate rails in adjacent track circuits are connected by heavy "diagonal bonds" so arranged that the breaking down of any insulated rail-joint will short-circuit either the relay or transformer and prevent the giving of a false clear indication. Cross-bonding between tracks may be effected by making connection, at any point desired, to the rails, which are made continuous by the diagonal bonds.

The bonds in question are made up of flat copper strips of large cross section wound in the form of a spiral, the turns being suitably insulated from each other. The coils, when wound, are heavily taped and then impregnated as in the case of the transformer coils. These coils are assembled in pairs in flat iron cases and mounted on extended ties. A connecting chamber is provided in the case between the coils, in which all the coil-ends terminate, and where all connections to the rails, relays, and transformers are made and then concealed by a suitable cover. The copper connections to the rails after leaving the bonds go directly downward and under ground to the rails where, after passing a short distance above ground to insure flexibility they are connected. This construction conceals the copper as much as possible, and reduces theft to a minimum. Energy is supplied to the track circuits directly from the low-voltage high-current windings on the line transformer, through adjustable cast-iron resistance grids, which limit the current flow when a train is standing at the transformer. These grids are mounted in separate perforated cast-iron boxes. The moving contacts are mounted on a horizontal wooden bar, to which motion is imparted by a small split-phase induction motor having two stationary windings. One of these windings is connected directly to the reactance-bond secondary, and the other directly to a low-voltage tap on the line transformer. When thus connected, a phase difference exists between the two coils and rotation of the armature is thereby produced.

Of the energy in the two relay windings, that supplied by the transformer direct is by far the greater. This requires but a small amount of energy from the track to give positive action of the relay, and as a result very long blocks can be operated with comparatively little energy, as evidenced by the fact that in this installation track circuits 8,880 ft. long are operated with energy fed in at one end. As alternating current only can cause the relay to operate, it is immune to the effects of direct current. All contacts and other working parts are made visible by glass-covered openings. Watertight construction is effected by using rubber gaskets. These relays are positive in action, and give an exceptionally heavy rubbing pressure between the contacts in closing, and an extra wide opening when de-energised. Contacts can be provided, as required, up to a maximum of four front and four back per relay. They are insulated to withstand a breakdown pressure of 3,000 volts alternating current.

The track circuit control relays are to hold a given signal at stop until the train is out of the overlap for the next signal in advance. These relays must be able to carry continuously and break the entire current flowing to the track circuit at the rear of a signal, and, of course, must continue to do so without injury. These relays as designed will carry an alternating current of from fifty amperes to seventy-five amperes, and break the same at twenty-five volts continuously without overheating and without perceptible arcing, although the current required to be carried in practice is much less than this. The construction and operation of these relays is similar to that of the track relays except that the contacts are made very much heavier, and the necessary phase displacement to produce rotation is effected by a small reactance coil, placed in series with one of the relay windings. There are a great variety of uses to which these relays can be adapted by simply changing the windings or contacts or by the addition of stock parts.

When wound to a low resistance they may be used as track relays, with contacts to the number of four front and four back, and when equipped with heavy contacts they can be used for the control of low-voltage heavy currents as already described. When equipped with carbon to carbon contacts they will break small currents of high voltage (up to 600). When wound to a high resistance they may be used as line relays with any reasonable equipment of contacts desired. By adding an upward extension to carry a small semaphore arm, they can be used as tower indicators, and, when placed in a suitable case, as switch indicators. The movements when placed in a case and equipped with a shutter and suitable contacts can be used as light signals for tunnel work. Furthermore, the feature which this relay possesses of operating in one direction with a given phase relation and in the opposite direction when said phase relation is reversed (and since a given reactance or resistance is necessary to produce rotation in a given direction), the possibility of false operation due to foreign currents or crosses is much more remote than in the case of direct-current relays and certain other alternating-current relays. This feature also makes it possible in many cases to use but one line wire where two would otherwise be required.

The motor-control relay is so controlled by the three track circuits in advance of a given signal that it cannot close until the train is out of the overlap for the next signal in advance. This relay directly controls the clearing of the signal, and is of the alternating-current tractive type. It is designed so that a uniform magnetic pull is exerted on the armature, notwithstanding the fact that the current in the magnetic coils alternates. In many respects it is similar to the direct-current track and line relays manufactured by this company.

The signal mechanism employed is a two-arm movement, and is operated by a small single-phase induction motor, which is connected through suitable gearing to a slot wheel. Projecting from the sides of the said slot wheel are pins which as they come around engage the slot dog in such manner as to clear the signal in case the slot is energised. The slot magnet is designed to operate on alternating current, and to give a uniform pull without noise and vibration. It has an exceptionally high "drop away" point. The movement of the blade in clearing is limited by the stop arm, which becomes effec-

Digitized by Google

tive only when the slot is energised, and is so arranged that the signal blade is brought precisely to, and held at, the clear position, no matter what the speed of clearing. The circuit-breaker contacts are enclosed in a dust-proof case with a glass front, which is mounted at the top of the mechanism. The dash-pot is of the buffer type, allowing a free initial movement of the blade in returning to the stop position. All the signals are lighted by two 4 c.p. 50-volt lamps connected in parallel.

All relays are housed in wooden boxes, which in turn are enclosed in cast-iron boxes. In the lower part of the iron boxes are mounted the terminal boards, where all outgoing wires terminate on suitable binding posts and to which all apparatus within the boxes themselves are connected by flexible leads. All transformer secondary fuses are also mounted on this same board. The relay-boxes, grid-boxes, and line transformers are mounted one above the other on suitable stub poles provided for the purpose.

THE PRINGLE "TANGENTIAL" TROLLEY-WIRE SUSPENSION

IN our description of the tramway extensions at Derby (ELECTRICAL ENGINEERING, December 19th, 1907), we gave some particulars of the new method of trolley-wire suspension employed there, which is the invention of Mr. P. J. Pringle, Borough Electrical Engineer and Tramways Manager to the Burton-on-Trent Corporation. Mr. Pringle has now given us some additional information with regard to his system. It has been erected on about 1½ route miles with bracket arms and about 1¼ miles with span wire in Derby by the tramway department staff of that town, and has given no trouble there during the few weeks that these routes have been in operation. In Burton, all parts of the line in which there is the greatest rigidity, have been changed over to this system, and it is being given a trial in about half a dozen other tramway undertakings.

Mr. Pringle points out that after a tramway has been running three or four years, trouble with breakages of the trolley wire at the ears are usually experienced, and he tells us that in Manchester, Dublin, and Berlin fractures of the trolley wire have become so frequent that it has been necessary to put a supporting anchor wire on either side of nearly every ear, so that, in the event of a fracture, the anchor wire will hold up the trolley wire.

With circular wire, however carefully finished off the ears may be, there must be a blow between the ear and the trolley wheel to a more or less extent, together with arcing at the trailing ends of the ears. When the soldered ear is replaced by the clinched ear, it is necessary to make the sides of the ear a little stouter, and, although breakages are less liable to occur, these two effects are slightly increased unless a grooved or "figure 8" wire is employed. This, however, makes it necessary to keep the trolley wheel turned up regularly from time to time during its life, and Mr. Pringle contends that there is a more rapid wear of the trolley wheels, and on the trolley wire towards the centre of the spans, which is due to the difficulty of keeping the grooves of the wire on the horizontal plane after it has left the ears. Another cause contributing to the fracture of the trolley wire at the ear is that, in spite of the flexibility of bow-string suspension and span-wire

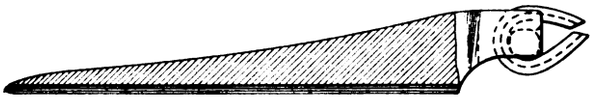

FIG. 1.—EAR USED FOR PRINGLE SUSPENSION. SCALE: ONE-THIRD FULL SIZE.

construction, there is still a certain amount of hinging action at the ends of the ears, so that the wire at this point is submitted to alternating stresses.

All these tendencies, Mr. Pringle claims, are eliminated by his new system of suspension, the main principle of which is the supporting of the trolley wire and its fittings by means of suspension wires approximately tangential to the natural curve of the trolley wire. Figs. 1, 2, and 3 show the method as applied to bracket-arm suspension. In Fig. 3 the ordinary bow-string and the Pringle suspension are illustrated side by side for the purposes of comparison, the former being to the front and the latter to the back. Instead of an ordinary ear, two 8-in. ears (Fig. 1), similar to those used for anchor ears in ordinary work, are employed. These are placed with their tips about 5 ft. from the centre of the suspension, on either side, and the trolley wire

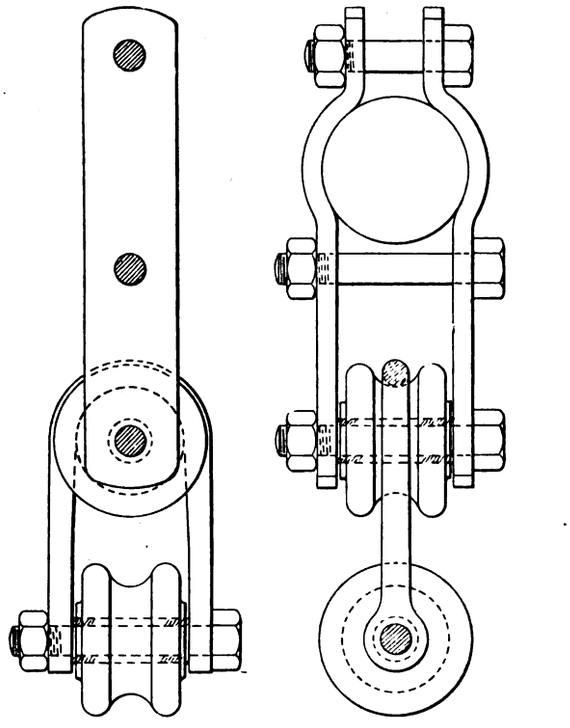

FIG. 2.—BRACKET ARM ATTACHMENT FOR PRINGLE SUSPENSION. SCALE: ONE-THIRD FULL SIZE.

is soldered into them in the usual way. A suspension wire, usually of 7/12 gauge, is fastened between these two ears, passing over the lower grooved insulator shown in Fig. 2, but not fixed to it except when anchoring is required. The construction of the fixture to the bracket arm is clearly shown in Fig. 2. Both the upper and lower insulators are of the brown-ware reel pattern.

The downward pull of a 000 trolley wire on an ordinary ear is about 60 lb. with the average distance between supports, and in the case of the Pringle suspension it is transferred to the insulator, while the force on the ears is purely tensile. There is sufficient flexibility to allow a vertical motion of the trolley wire of about 1¼ in. and a horizontal motion of about 3 in. Besides diminishing enormously the alternating stresses on the trolley wire at the ears, it is found in practice that the blow on the wire as the trolley passes on to it from the ear is greatly reduced. The form of ear is "non-fouling"; the ear is in soldered contact with only the top half of the wire, as owing to the stress being almost parallel to the wire there is little danger of peeling away, and consequently no necessity for a great depth of groove. The ears are milled out a few

Digitized by Google

mils larger than the actual diameter of the trolley wire, and the latter is tinned previously to applying the ears. Two small thumbscrew clamps are used for holding the trolley wire tight down in the groove of the ear during the soldering process.

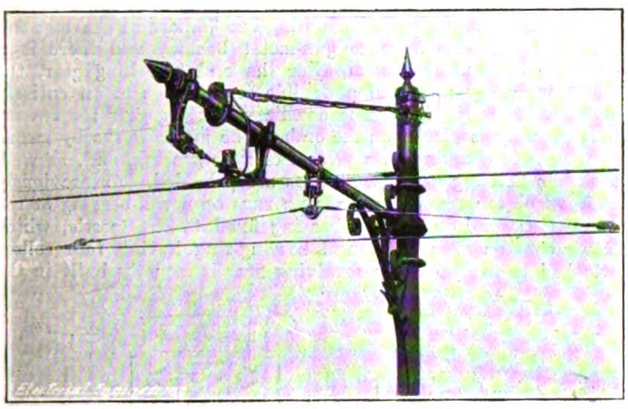

FIG. 3.—BRACKET ARM WITH ORDINARY BOW-STRING SUSPENSION AND PRINGLE TANGENTIAL SUSPENSION.

A number of tests have been made by Mr. Pringle, using 000 B. & S. trolley wire 0·409 in. diameter, and with the 8-in. ear used on straight line work, the ear casting has broken at stresses of 3,000 lb. without the ear attempting to leave the wire.

With the pull-off ears, which are about 12 in. long

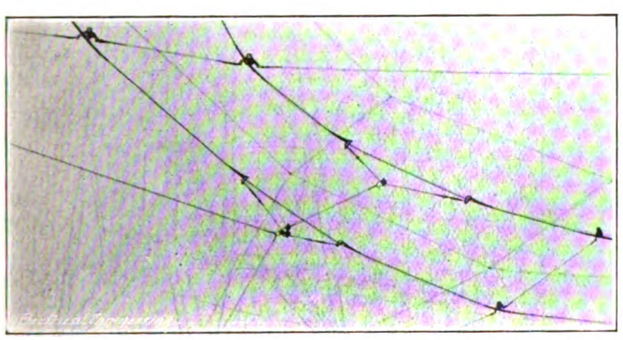

FIG. 4.—USE OF THE PRINGLE SUSPENSION ON A CURVE.

and of a stronger pattern, several tests have been made to prove that the trolley wire will fracture (requiring a stress of some 6,000 lb. to effect this) without any signs of the soldering giving way.

Mr. Pringle is now experimenting with malleable iron ears, which would not be feasible under ordinary

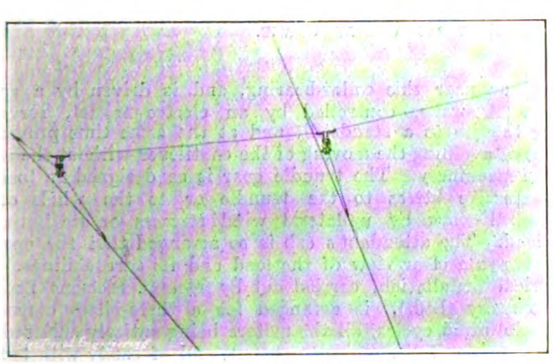

FIG. 5.—SPAN-WIRE SUSPENSION.

conditions, as malleable iron is unsuitable as a current-collecting surface. He informs us that the soldering with malleable iron ears has given just as reliable results as gun-metal, under stresses sufficient to fracture the trolley wire. It is anticipated that the use of malleable ears will tend to cheapen the cost of construction, which is already no greater than that of the ordinary suspension.

Previously to using the brown-ware reel insulator for both primary and secondary insulation, Mr. Pringle had fifty pairs of these under continuous test at 500 volts at his power station, where they were exposed to weather and any dirt or dust that might be about. Even in very heavy rain the leakage current from these insulators was only about 20 milli-amperes, and when the rain moderated the insulation at once rose. The same set of insulators were placed under test at 2,000 volts alternating for several months continuously with satisfactory results.

Fig. 4 shows the method of using the Pringle system on a curve. All bends in the line and pull-offs have

FIG. 6.—PRINGLE TRIPLE TANGENTIAL SUSPENSION.

the angle halved, so that much easier running is given, and high speeds are possible on bad pull-offs. It is also claimed that side wear on the wire is reduced.

On span-wire work (Fig. 5), the new suspension costs slightly more than ordinary span-wire work, but if all the advantages claimed are fully borne out in practice, it is evident that the saving in repairs and maintenance will far more than counterbalance the slight difference. Fig. 6 shows a modification, in the form of a triple tangential suspension, to reduce the sag in a trolley wire when higher speeds are required than those in ordinary tramway work. In this illustration one wire is supported on this system, and the other on the ordinary span-wire system, to show the difference in sag.

We are asked to state that Messrs. G. W. Green & Co., who are the sole licensees of the system, have assisted in working out the necessary details in its construction. The Consolidated Accessories Co. are the selling agents.

Franco-British Exhibition.—In connection with the movement to organise a co-operative electrical exhibit at the Franco-British Exhibition, by the electric supply companies of London and electrical manufacturing firms (ELECTRICAL ENGINEERING, Vol. II., p. 964), the following firms have now expressed their willingness to take part in the scheme. Full details of the scheme are being prepared, and in the meantime Mr. C. G. Northcote, the organising manager of the electrical section, will be pleased to hear from any other firms who are desirous of supporting the movement:—Armorduct Manufacturing Co., Ltd.; Berry Skinner & Co.; British Thomson-Houston, Ltd., British Prometheus Co., Ltd.; British Westinghouse Electric & Manufacturing Co., Ltd.; Bertram Thomas; Crompton & Co., Ltd.; Dowsing Radiant Heat Co., Ltd.; Edison & Swan United Electric Light Co., Ltd.; Foster Arc Lamp & Engineering Co., Ltd.; Huntalite Co.; Imperial Lighting Co.; Langdon, Davies Motor Co.; Linolite Co.; Marconi's Wireless Telegraph Co., Ltd.; Oliver Arc Lamp Co., Ltd.; Perfecta Seamless Tube Co., Ltd.; Robertson Electric Lamps, Ltd.; Simmonds Bros.; Sun Electrical Co., Ltd.; Union Electric Co.

A 100-TON ELECTRIC WHARF CRANE

A 100-TON electric wharf crane has been recently constructed and erected for the Dublin Port and Docks Board by the Vereinigte Maschinenfabrik Augsburg und Maschinenbaugesellschaft, of Nuremberg, Germany, and mechanical details are shown in Fig 1, and a general view of the crane is given in Fig. 2. The design is of a light and open type, and the two main girders of the jib are joined throughout their entire length by horizontal cantilevers, by means of which the jib has considerably more rigidity against the horizontal stresses. Above and on both sides of the crab-travelling track is a railed ladder, by means of which the crab is at all times accessible. Vertical crossbars take over the stresses caused by horizontal and wing pressure, and by means of these the stresses are transferred to the pillars or through the horizontal ring-girder on to the supporting frame. The scaffolding is connected by anchor-bolts to the foundation body, which is provided with an iron centre, are two brakes working quite independently of one another. One brake is worked by an electric brake magnet, and the other is a mechanical and automatically working Lamell brake of the builders' patent type, which ensures even lowering, independent of the attendant's skill. The important bearings are fitted with interchangeable gun-metal bushes, and there is a complete lubricating system. For the crab-travelling gear, the motor works by means of a flexible coupling on to an entirely enclosed worm gearing. The auxiliary hoisting gear for twenty tons capacity is placed on the crab. The motor works by means of a flexible coupling on a system of spur gearing, and, as with the main hoisting gear, two brakes are provided. As previously mentioned, the revolving crane-jib runs on a rail-bearing at the foundation, and in a collar-bearing fixed to the trestle, which latter consists of a horizontal bearing-ring having four rollers attached to the jib. The revolving gear is securely built in the

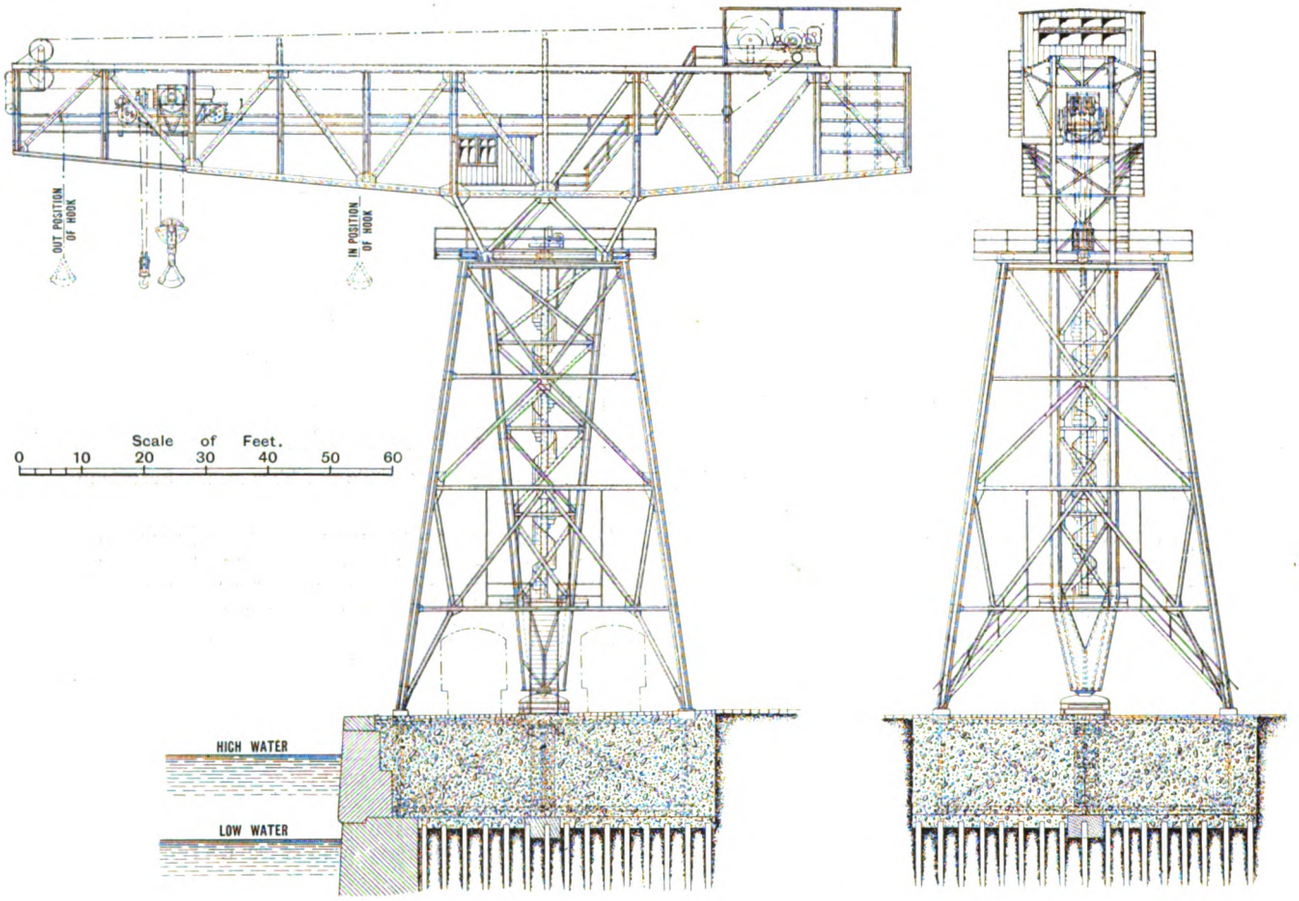

FIG. 1.—GENERAL ARRANGEMENT OF 100-TON ELECTRIC WHARF CRANE.

so that all vertical and horizontal stresses are sustained by the steel structure, that is to say, the concrete is not called upon to withstand any bending stresses. The revolving jib on which the crab runs is provided with a rear arm for the counterweight and with a vertical pillar. This revolving part runs on roller bearings at the base, whilst the horizontal stresses of the upper part are carried by the collar-bearing attached to the stationary trestle, and provided with rollers. The counterweight is placed at the back cantilever, and consists of a stiffened plate tank filled with concrete. A spiral railed staircase leads to the upper platform of the trestle, and easy access can thus be had to the attendant's cabin, and to the two stairways attached to the crane jib, as well as to the compartment containing the gear. The hoisting gear and the crab-travelling gear are both located in the house situated at the rear arm of the jib. The driving of the hoisting gear is by means of a flexible coupling, and an entirely enclosed system of spur gearing with cut teeth, which further operates by means of spur wheels on to two grooved rope drums. The rope is so led from the hook pulley on to these drums that any side tension or unevenness of the pulley—either to the highest or lowest position—is rendered impossible. There jib pillar near this collar-bearing, and is driven by a special motor. A brake, controlled by an electro-magnet, serves to bring the jib to a standstill, and at the same time provides a means of avoiding the moving of the cantilever without the action of the machinery. The trundle gear is so designed as to avoid an excessive stress to the trundle or to the whole of the structural work by unilateral wind stresses or oscillating of the load. The attendant's cab is so arranged that the operator has always a clear view of the load and its surroundings. The electrical installation, carried out by Messrs. Siemens Brothers & Company (Ltd.), is arranged for a three-phase current at 346 volts at 25 cycles, all the motors being entirely enclosed and fully capable of the requisite output, and of easily withstanding sudden rushes of current. The current is taken to the motors and electric magnet for the auxiliary hoisting gear situated on the crab by a sliding contact fixed on the inside of the jib. The following are the leading dimensions—Maximum radius, from the outer edge of the quay wall to the hoisting rope axis, with a 100 tons 45 ft., with 20 tons 50 ft. Minimum radius, from revolving axis to the hoisting rope axis, 100 tons, 30 ft. Revolving axis to outer edge of quay wall, 30 ft. Height of

Digitized by Google

lower edge of load hook, when at its highest position over the quay wall, with 100 tons 70 ft., with 20 tons 70ft. Greatest height of lift, for 100 tons 100 ft., and for 20 tons 100 ft. The working speeds are: lifting, 100 tons, 5 ft. per minute; 50 tons, 10 ft. per minute; 20 tons (auxiliary hoisting gear), 20 ft. per minute (with reversed wheel gearing); speed of crab, 28 ft. per minute; duration of a complete crane revolution, 8 to 10 minutes. Working at low speed, the lifts are, 100 tons, about 3 ft. per minute; 50 tons, about 6 ft. per minute (with reversed wheel gearing); speed of crab, 22 ft. per minute; and duration of a complete crane revolution, 10 to 12 minutes.

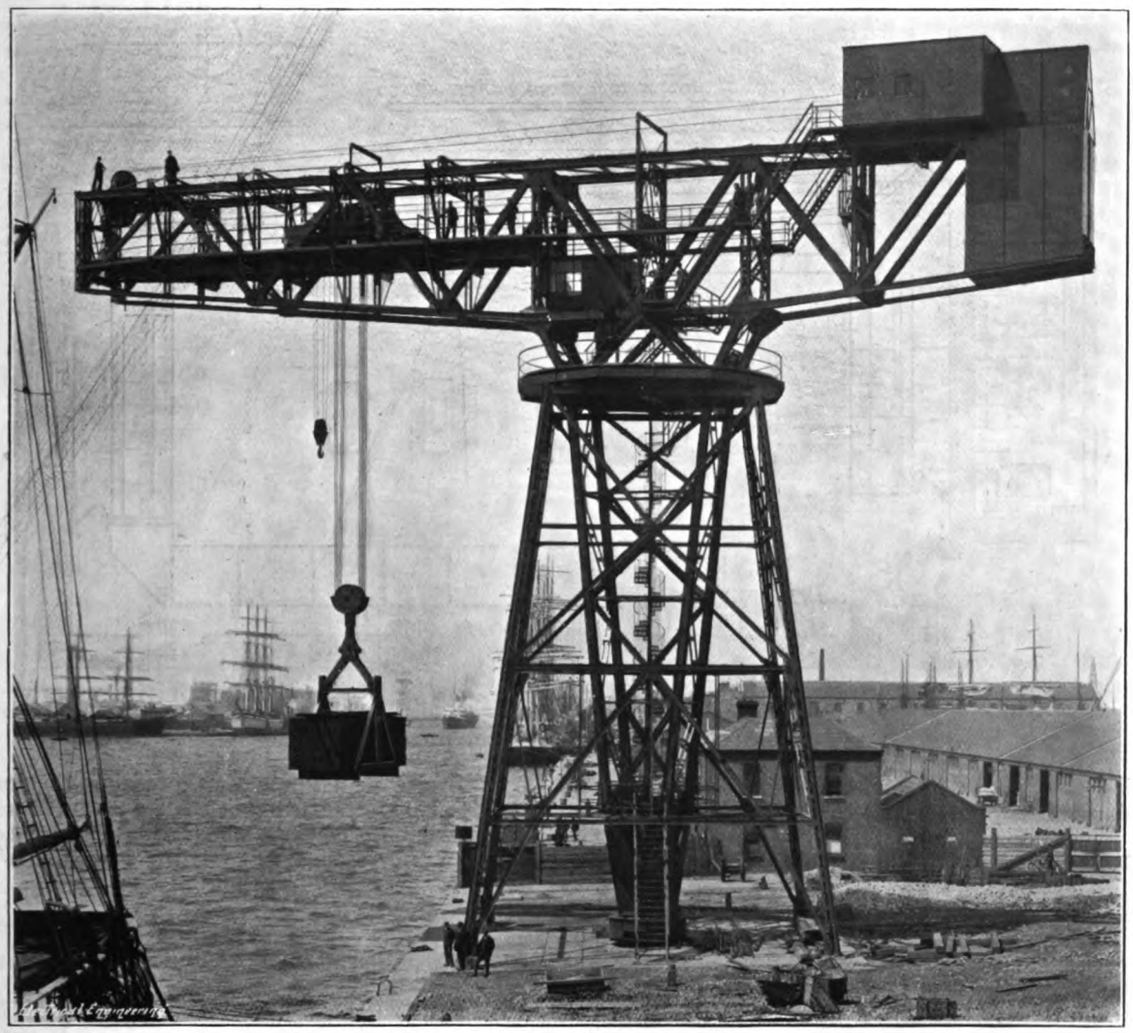

FIG. 2.—VIEW OF 100-TON ELECTRIC WHARF CRANE AT DUBLIN.

NEW TRUNK TELEPHONE EXCHANGE AT BRADFORD

ON November 9th the Trunk Exchange at Bradford was transferred from the north to the south end of the Post Office building, where a new room had been recently completed. The walls are of white-glazed bricks, the roof has both ceiling and lantern lights, there are windows on three sides, and the room is, in consequence, admirably suitable for the purpose. It is heated by hot-water radiators, whilst ceiling pipes on the same system are fixed to prevent cold air falling down upon the operators' heads from the roof windows. Fire buckets filled with sand, and iron cylinders containing asbestos cloths, are placed around the room in convenient and handy positions in case of emergency.

The new switchboard, constructed and wired by the British Insulated & Helsby Cables, Ltd., consists of 16 three-panel Trunk and Junction switch sections, as shown upon the plan in Fig. 1. Included in this number are the record and reserve sections, the latter being fully fitted for the purpose of transferring the trunks from those sections which are thrown out of use for their periodic overhaul. The first 11 trunk panels are fitted up for concentration purposes during slack periods, and in accordance with standard methods. Provision has been made for extending the switchboard, as shown by dotted lines, along the west side of the room.

In the design of the switchboard every effort has been made to reduce risk of fire to a minimum. Its framework of iron is rigid and strong, and has been painted to prevent rust, and it is earth connected. The cable-bearers and troughings are also of iron. The front of the board, which presents a handsome appearance, has its polished mahogany facings and continuous plug shelf, as well as the ebonised panels, backed with uralite. Above the panels and along the whole length of the suite adjustable reflectors with incandescent lamps serve to illuminate the board.

The three-panel sections are separated by an intermediate panel carrying the ticket racks and switches.

Fig. 2 has been taken to show the apparatus used in connection with the telegraph call wires. The trunk panels of two sections, Nos. 20 and 21, are shown. On

Digitized by Google

either side are the junction panels, No. J10 only being included on the illustration. Junction panel J11 is on the right of 21.

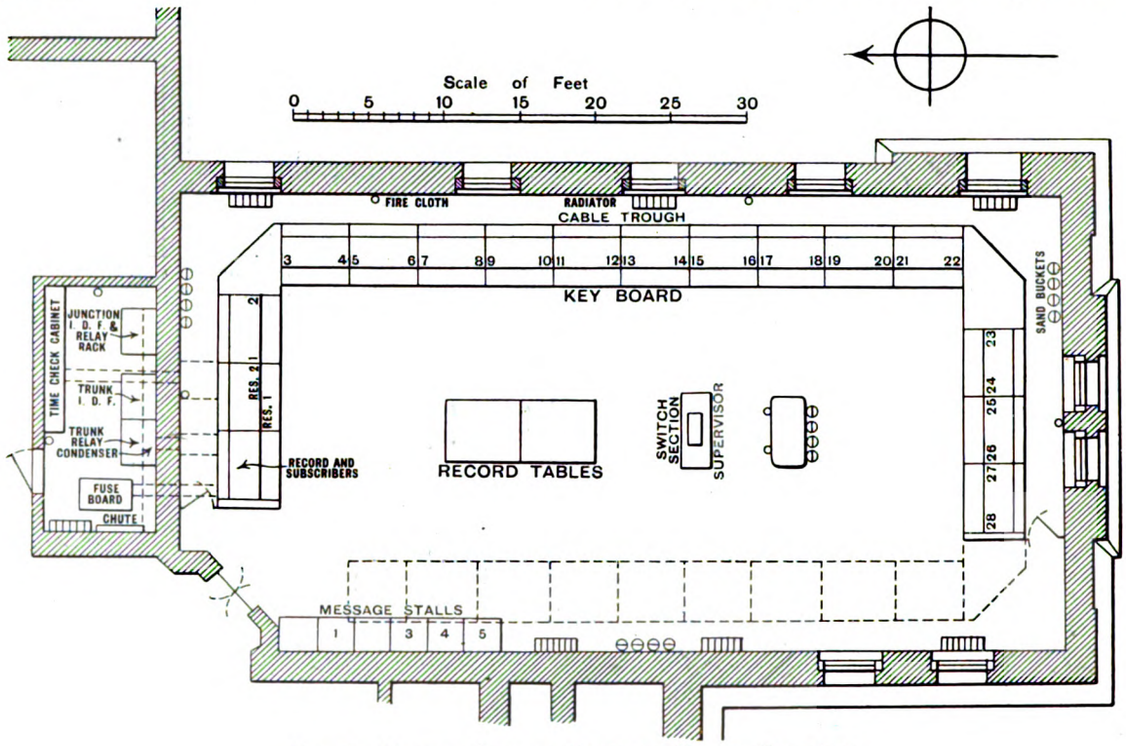

FIG. 1.—GROUND PLAN OF BRADFORD TRUNK EXCHANGE.

During the busy periods of the day the ordinary methods of transmitting the particulars of the calls over the trunk lines between Bradford and certain other trunk centres are rendered unnecessary by the use of the telegraph direct call wire system, resulting in an increased revenue of the earning capacity of the lines, and avoiding loss of time. The services of an additional operator are necessary. She is seated between the ordinary operators at the detachable desk fitted in the front of the keyboard opposite the intermediate panel. Her headgear sounder, with its perforated band, is shown against the sloping desk. The Morse key is immediately below. Upon one of the trunk lines an earthed telegraph circuit is superimposed, whose signals in no way interfere with the conversation taking place over that particular line. The trunks controlled by this call wire are divided into groups for incoming and outgoing traffic. By this method of working the trunk lines are exclusively devoted to conversations, whilst all messages and particulars of calls or complaints are passed over the call wire. To facilitate transmission of signals, certain phrases in frequent use are sent in code.

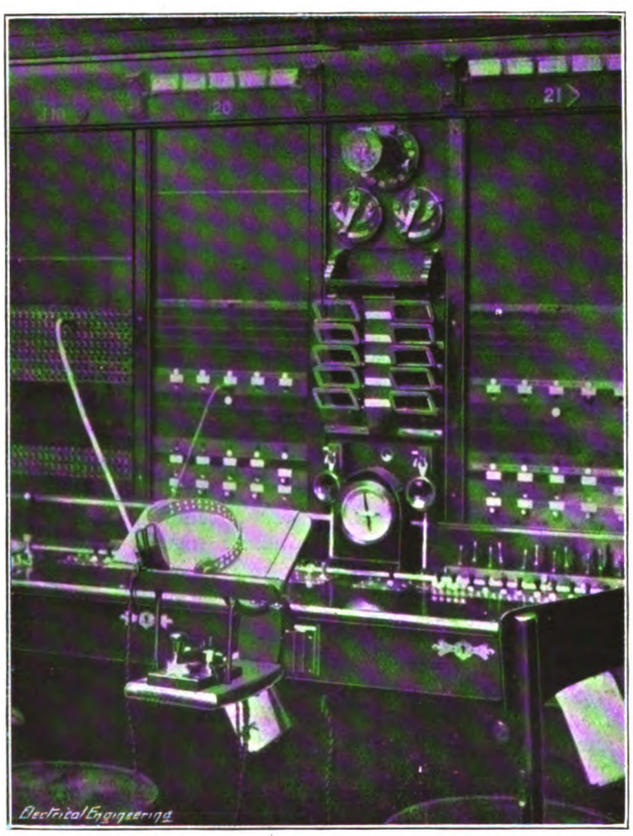

FIG. 2.—A PAIR OF TRUNK PANELS, WITH INTERMEDIATE TELEGRAPH CALL ARRANGEMENT.

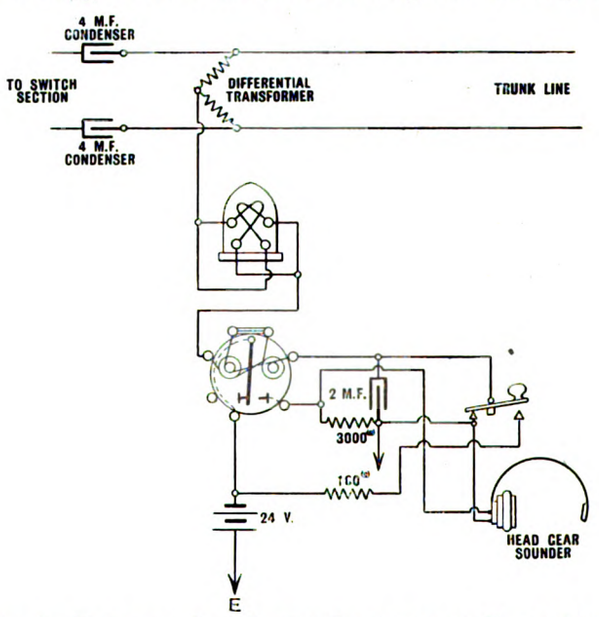

FIG. 3.—TELEGRAPH CALL CIRCUIT SUPERPOSED ON TRUNK LINE.

Digitized by Google

Fig. 3 is the skeleton diagram of the circuit. Each station is joined up alike. The currents from the sending station pass through its own relay in a "spacing" direction; the sending operator therefore does not hear her own signals. Her sounder is only actuated by the distant stations signals. The differential galvanometer and condenser are joined up in such a way as to retard the telegraph battery currents, and reduce the possibility of disturbance on the trunk line. The sounds are produced by the movements of a small plunger in the headgear sounder. This plunger is propelled from an iron tube, and attracted by an iron screw when the local circuit of the relay is closed, and it is brought back to normal at its cessation by means of an antagonistic spring. The volume of sound is small, and does not inconvenience the operator.

Each trunk operator is provided with an additional receiver, which, when out of use, hangs upon a lever rest under her set of ticket racks to the left or right as the case may be. This is for use in connection with long-distance calls.

The junction panel is reserved for junction multiples, and transfer multiples between section and section for through trunking. The former occupy the centre portion, the latter the lower portion. In Fig. 4 skeleton diagrams are given, including the junction side of the trunk cord circuit, where means are provided by which the operator obtains both audible and visual "engaged" signals. Should either junction or transfer line be engaged, there will be an earthed battery with its positive pole connected to the bush of each jack of the circuit, which will find a path *via* the tip of the red plug and the earthed relay R7, producing a click in the receiver, and causing the lamp to glow.

In the centre of the trunk panels in Fig. 2 is seen the red test lamp L3. Below this are five lamps and jacks in connection with the calling circuit of transfers from the local and trunk sections. The pilot lamp, common to the circuits on the board, follows. Below these are the time check keys, line lamps, trunk jacks, night concentration jacks with plugs inserted, and the wire links for cutting out the relays when cord testing takes place.

Six pairs of plugs and cords are fitted, and provision is made for a seventh pair. In each cord circuit are three lamps. These are protected by a guard against

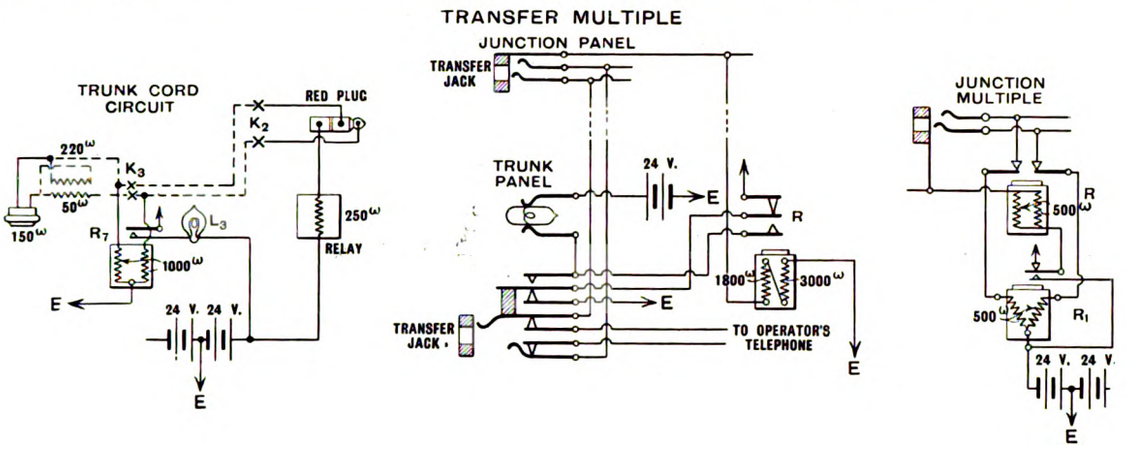

FIG. 4.—DIAGRAM OF TRUNK CORD CIRCUIT. TRANSFER MULTIPLE AND JUNCTION MULTIPLE.

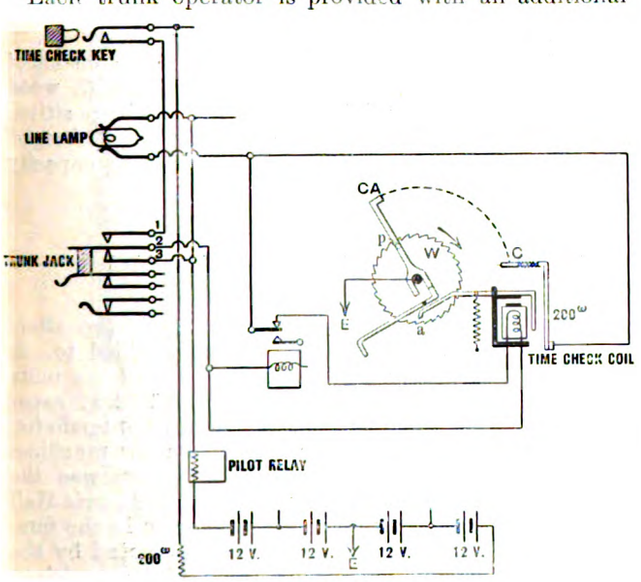

FIG. 5.—TIME CHECK.

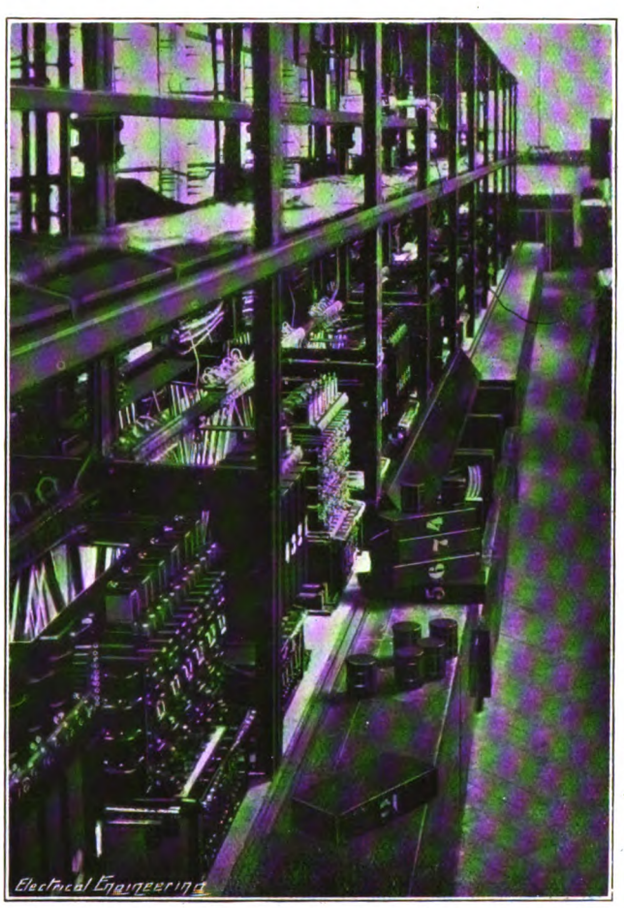

FIG. 6.—BACK OF SWITCHBOARD WITH ALL SLIDING PANELS REMOVED.

Digitized by Google

damage from falling plugs due to any slip on the part of an operator.

The keyboard has a capacity for 20 call-wire keys, but only five are fitted. By depressing one, the operator is in direct communication with one of the junction operators of the National Telephone Co.'s Exchange.

A calculagraph for recording the exact times of each conversation is placed on the keyboard in front of each junction panel for the joint use of two operators. A coupling key is also provided for each keyboard for connecting the adjacent sets together.

Below the keyboard are wire baskets for waste paper, removable panels lined with uralite, and a continuous foot rail for the comfort of the operator.

In this exchange the time check is fitted to assist the operator to control the duration of a conversation. An electrical seconds pendulum is adjusted to give second impulses through the relays controlling the driving gear, which revolves the spindle carrying the toothed wheels in connection with each time check coil. The skeleton diagram is shown in Fig. 5. It will be noticed that when a plug is inserted in the trunk jack, contacts 1 and 2 are made, while 2 and 3 are broken. At the commencement of a conversation on the trunk line the operator depresses the time check key, which thereby closes the battery circuit through the time check coil, lamp, and pilot relay. The coil becomes energised, the armature is actuated, its remote end, *a*, lifts the tumbler arm, C A, whose pin, P, engaging with the revolving toothed wheel, W, is carried round towards C.

At the expiration of three minutes the arm reaches the hinged platform contact, C, earthing the line lamp which now glows. The operator ascertains if an extension of time is required, and if so depresses the key twice. The armature is actuated, and brings into operation a curved resetting rod, not shown, which strikes the arm off the wheel. The arm then falls back to its normal position. The second current causes it to re-engage for a second period. Should the plug be withdrawn before the expiration of the three minutes the coil is energised immediately the tumbler arm reaches the platform C, and the arm struck off.

If the plug is not withdrawn, or the key depressed, the arm is carried further round, and pressing down upon the movable platform is pushed away so that its pin is disengaged from the wheel, and the arm is restored by gravity.

Fig. 6 shows the back of the switchboard with the iron sliding panels removed to show the relays, &c. The power cables are supported on iron brackets in the roof of the section, and their ends terminated at tags mounted on vulcanised fibre bases.

The record tables, supervisors switch sections, and telegram stalls are of the standard types.

The intermediate distributing frames call for no special mention. The usual switchboard cables (42 and 84 twin wire, 12½ lb.) were laid between these frames and the trunk test board tags on the instrument side.

The machinery has been installed in the basement. The motor-generator for charging the cells is a 5·8 b.h.p. motor, coupled to a 70-volt, 80-ampere generator at 950 revolutions per minute. These are of the standard four-pole enclosed type, with carbon brushes, ventilated by means of a fan on the end of the armatures. The coupled machine rests on a common bed plate, and is earthed by means of a carbon brush running on a coupling.

The motor-starting panel consists of an ironclad starting switch with overload and no-voltage release, protected by two ironclad S.P. cut-outs, and an ironclad D.P. switch, all mounted on an iron frame. The voltage of the generator is controlled by a rheostat on the power board, and can be varied between 50 and 70 volts.

The power board in the battery room is constructed of a slate slab enclosed in an iron cabinet and fitted with a Nalder automatic cut-out in the battery leads, an ammeter and voltmeter with their switches, two electrolytic meters, a generator field rheostat, and three throw-over switches, two of which are five-pole, and control the charge and discharge of each battery, whilst the third is a six-pole switch to cross over portions of the battery to equalise their working.

The battery, supplied by the Chloride Co., consists of two sets of 24 cells, type SG4, nine-plate, with wood board separators, supplying 24 and 12 volt positive, and 24 and 12 volt negative, each set being charged and discharged alternate days. Its ultimate capacity is 240 ampere hours at the nine-hour rate.

EXTENSIONS OF GENERATING PLANT AT EASTBOURNE

THE Eastbourne electricity undertaking, originally started by a company and now carried on by the Corporation, has a longer history to look back upon than most electric supply undertakings, and it is of some interest to note the various changes in the generating plant installed from time to time, presenting, as they do, typical examples of what has been considered the best practice at various periods. With the exception of the early arc lighting, the system of supply, single-phase, with transformers, has remained all through, but the generating sets have ranged, as we shall see hereafter, from the machines driven by belting from countershafts familiar in the early 'eighties to the fine turbo-alternator just erected.

Before describing this latest extension we will give a brief historical sketch of the development of the undertaking. Electric lighting in Eastbourne started in 1882, in which year the Eastbourne Electric Light Company obtained a concession from the Hammond Electric Light and Power Co., and carried out the lighting of the parade with Brush arc lamps. A limited amount of incandescent lighting was attempted in series with the arc circuits, but this was superseded in the following year by the inauguration of a single-phase system with transformers. The original arc lighting plant was at the old Water Works, but was moved to a site in Junction Road in 1884, where the alternating plant was installed and gradually added to. It is interesting to trace the increasing sizes of the units adopted. The oldest machines were of 25-kw. capacity, and were driven by belting from countershafts. A pair of 75-kw. belt-driven Ellwell-Parker machines were afterwards added, and the next step was the installation of a 100-kw. rope-driven Lowrie-Hall machine. Some of the machinery is shown in the foreground in Fig. 1. A new era was inaugurated by the subsequent introduction of direct coupled sets driven by high-speed engines.

The career of the company closed by the taking over of the undertaking by the Corporation at the beginning of 1900, when, acting on the report of Mr. Hawtayne, the Corporation decided upon the erection of the present station at the east end of the town. This station was completed and supply commenced early in 1902. At first both stations were kept running, but the old alternating plant was finally shut down in July, 1902, although the arc lighter continued to run for a few months longer. The three direct coupled sets and the boilers were then moved from the old works and the former placed in the engine-room of the new station alongside the two Ferranti sets, which formed its initial equipment. At this stage, there-

Digitized by Google

fore, the equipment was as follows:—Two 400-kw. Ferranti engines and alternators, one 200-kw. E.C.C. alternator driven by Willans engine, one 150-kw E.C.C. alternator driven by Davey Paxman high-speed engine, and the small 50-kw. set for taking the day load, also driven by a Willans engine. These machines are shown in Fig. 2, which depicts the appearance of

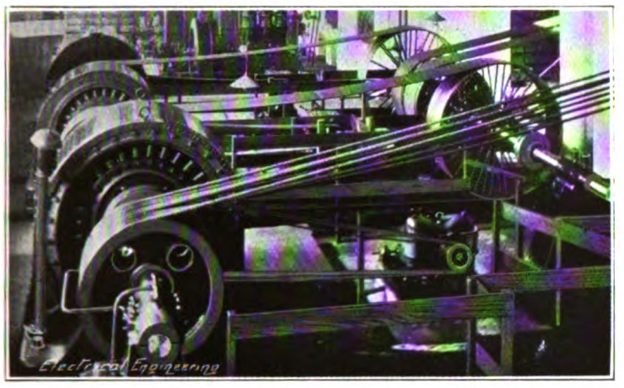

FIG. 1.—BELT AND ROPE DRIVEN PLANT IN OLD STATION.

the engine-room prior to the addition of the new turbo-alternator which has taken its place this winter.

We do not propose to give a full description of the whole of the station, as it is the purpose of this article briefly to recapitulate the different forms of generating sets which have been adopted from time to time, and to describe more particularly the very latest extension of plant which has been carried out.

The new set, which has been necessitated to keep pace with the rapidly growing load, consists of the 750-kw. Willans-Bruce Peebles turbo-alternator which is shown in Fig. 3. It has been possible to find room for this set and the extra boiler plant without any addition to the existing buildings, by a certain amount of rearrangement of the plant, both in the engine-room and the boiler-house. Another important feature introduced for the first time into the station is the provision of condensing plant, as all the older sets ran non-condensing. In this connection a large cooling pond, further details of which are given hereafter, had to be constructed.

The new set is placed across the east end of the engine-room in front of the switchboard, and the 50-kw. set partly shown on the extreme right in Fig. 2 has been moved to the other end of the room opposite one of the Ferranti sets. The generator is of Messrs. Bruce Peebles and Co.'s standard high-speed revolving field type with four poles. Its rated output is 940 k.v.a. at a power factor of 0·8 at 2,200 to 2,400 volts single phase, 50 cycles, and it runs at a speed of 1,500 r.p.m. The guaranteed overloads are 25 per cent. for two hours and 33 per cent. for half an hour, and the inherent regulation is specified to be such that the rise in voltage on switching off full non-inductive load shall not exceed 7 per cent., or, in the case of full inductive load, 17 per cent. The exciter is a four-pole machine rated at 15 kw., and coupled directly to the shaft. The maximum excitation required by the alternator, however, is stated not to exceed about 8 kw. The whole voltage regulation is carried out on the exciter shunt without any series rheostat. The exciter has, therefore, to work at times with a somewhat weak field, but is enabled to withstand these conditions without sparking by being provided with commutating poles. The outer end of the exciter shaft is provided with a ball bearing. The general construction of the alternator follows in most points the lines now becoming familiar with British high-speed designs. The frame is not of the entirely boxed-in type with a "chimney," favoured principally on the Continent. The casing is perforated with a number of holes which give ample access of air to the back of the stator core, and the general ventilation of the machine is assisted by a series of fan blades carried

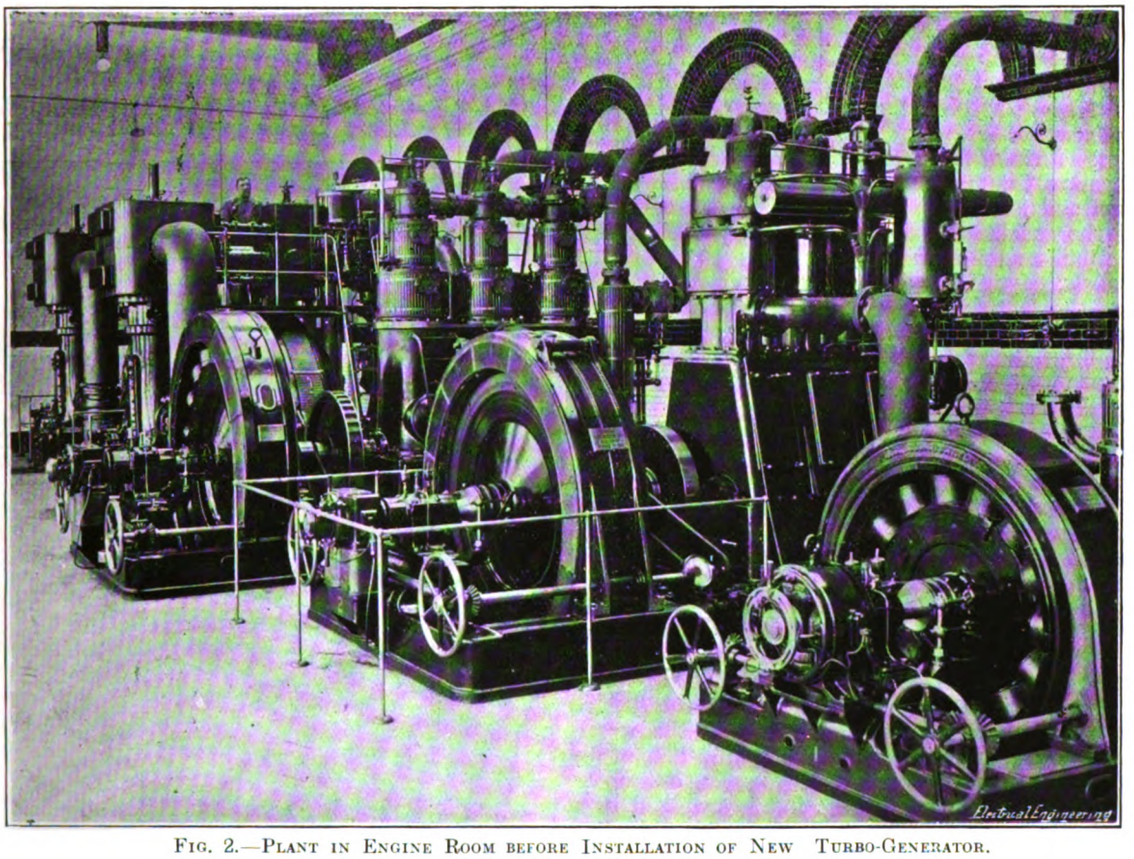

FIG. 2.—PLANT IN ENGINE ROOM BEFORE INSTALLATION OF NEW TURBO-GENERATOR.

Digitized by Google

on the rotor. The poles are of the salient type with the pole-shoes affixed after the bobbins have been slipped on. The construction is simple and substantial, particularly as regards the clamping of the coils. The asymmetrical appearance of the single-phase stator winding in comparison with that of a three or two-

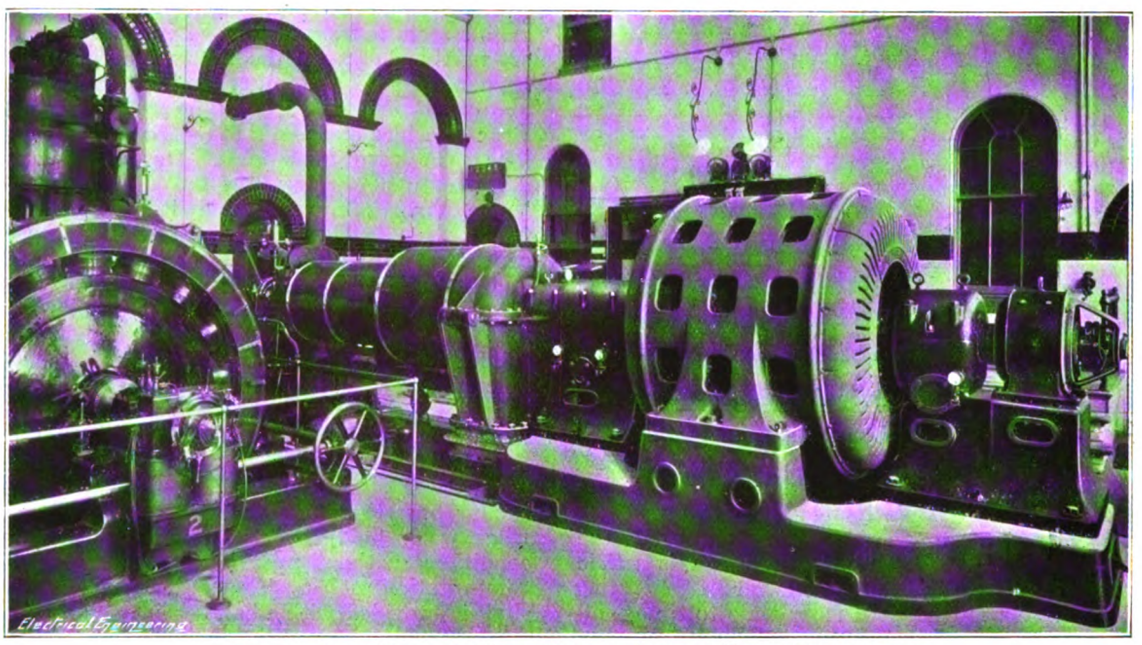

FIG. 3.—NEW WILLANS BRUCE PEEBLES 750 KW. TURBO-GENERATOR.

phase machine is at once apparent, and the somewhat large air-gap (about $\frac{5}{8}$ in.), necessitated in single-phase machines to obtain good inherent regulation, is also noticeable.

The turbine is of the standard Willans-Parsons type, with blading manufactured under the Willans and Robinson and Sankey patents. The general construction of the machine is similar to that of the turbine set described and illustrated in ELECTRICAL ENGINEERING, Vol. I., page 959, except for its somewhat smaller size, and the fact that the auxiliary motor for altering the speed by acting on the setting of the governor has not been thought necessary, as the set is placed so near the switchboard. Otherwise the governor gear is of similar design.

The condensing plant under the turbine, part of which is shown in Fig. 4, is of Messrs. Richardson, Westgarth, & Co.'s "contraflo" type. With this type of condenser it was not found convenient to bolt the condenser rigidly to the exhaust flange of the turbine and mount the condenser body on springs, as is often done in Messrs. Willans and Robinson's plants, so a flexible "concertina" joint has been inserted between the exhaust-valve and the condenser to make the necessary provision for expansion. The air-pump proper is of the familiar Edwards' three-throw type, driven through gearing by a 12 h.p. Rhodes single-phase commutator motor of the repulsion-induction type, running at 720 r.p.m. This type of motor is arranged to give a high starting torque as a repulsion motor when starting, but is switched over automatically so as to act practically as an induction motor when up to speed. Like all the other auxiliary motors it runs on a 200-volt circuit. A hot well pump and a force-pump are driven off the same shaft as the air-pump. The condenser is divided into several partitions, each drained separately; this drainage water is dealt with by the hot well pump, but the force-pump takes the water from steam not dealt with by the air-pump and the spray water. The circulating pump is of Messrs. Greenwood & Batley's centrifugal type, driven by a 12 h.p. slip-ring single-phase induction motor, manufactured by the Fuller Electrical Co. This set runs at 1,450 r.p.m., and can deal with 900 gallons per minute up to 25 ft. head. A Templer and Ranoe patent automatic atmospheric exhaust-valve is provided, which makes connection to the main exhaust-pipe of the other engines in the station when necessary.

The cooling water is taken to the new spray cooling-pond already mentioned. This is 89 ft. × 79 ft. 6 in. × 3 ft. 6 in. deep, and with a total capacity of 145,000 gallons. There are in all 80 spraying nozzles,

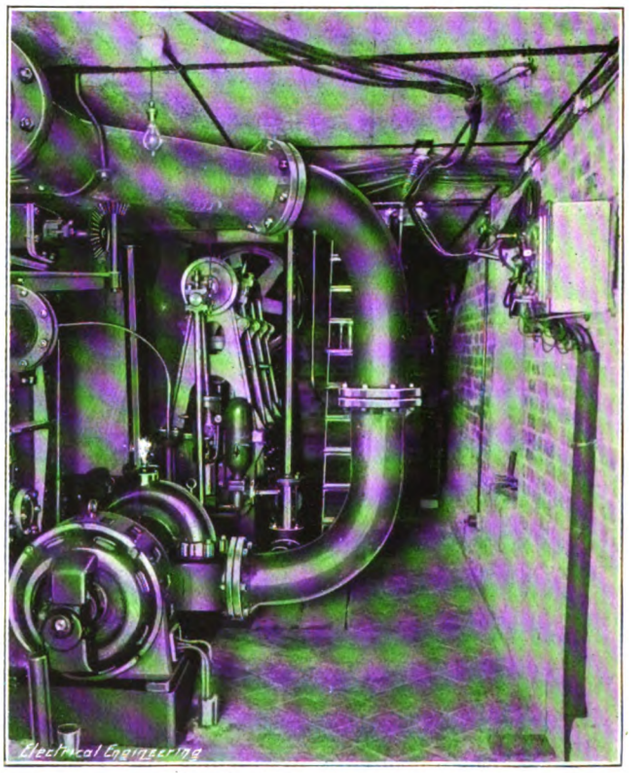

FIG. 4.—CONDENSING PLANT.

and from 70 to 75,000 gallons of water can be dealt with per hour. The pond itself was constructed by the Corporation by direct labour, and is lined with "Callendrite" bitumen sheeting, but the whole of the spraying equipment was supplied by Messrs. J. H.

Digitized by Google

Harrison, of Middlesbrough, whose "Simplex" type of nozzle shown in section in Fig. 5 is used. The nozzle itself is made of gun-metal, the central portion being in the form of an inverted hollow cone, having two holes through the sides set at such an angle with each other that water passing through them from the lower side forms two streams which strike each other, and are thus broken up into fine particles. In this form the water offers a very large surface in proportion to its bulk, which is freely acted upon by the atmosphere as it falls through it into the pond below.

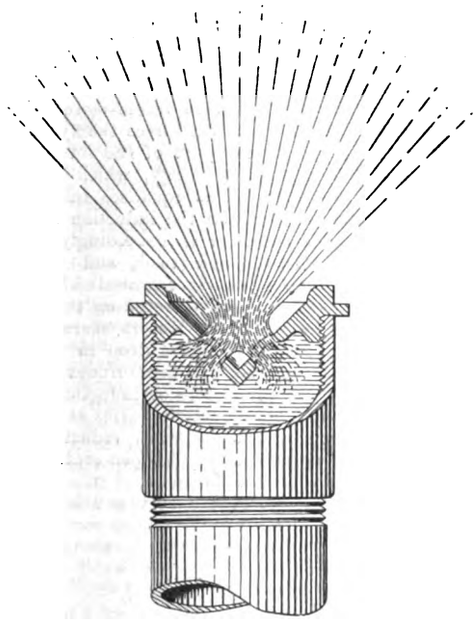

FIG. 5.—SECTION OF SPRAYING NOZZLE USED IN COOLING POND.

There is no doubt that the cooling obtained is quite as good, or, perhaps, even better than with the ordinary wooden cooling tower, but, of course, in cases where space is limited, the latter has to be used.

The switchboard extensions consist of a single machine panel and a spare panel mounted alongside and continuous with the old-fashioned Ferranti board. All the new switchgear is of Messrs. Cowan's, Ltd., manufacture, with Messrs. Everett & Edgcumbe's instruments. The main oil switch is provided with Mr. Leonard Andrew's patent discriminating reverse-current release, but not an overload attachment. The panel itself contains only the operating handle, relays, instruments, and exciter switchgear. The main oil switch is fitted in a separate room behind the wall, and the exciter field rheostat is placed below the floor. A single-pole field breaking switch with non-inductive resistance is provided. The spare panel, when complete, will carry a bus-bar recording voltmeter and a total output meter. No new synchronising gear has been provided beyond provision for plugging on to an extension of the existing Ferranti synchronising bar.

The room behind the switchboard, which now contains the new H.T. switchgear, was formerly a test-room before the new test-room upstairs was equipped. It also serves as a works sub-station, containing a pair of small transformers, stepping down to 100 and 200 volts respectively for station lighting and auxiliary motors respectively. These transformers are provided with connections from a series of tappings to regulating switches, by which the secondary voltage can be adjusted in six or seven steps of about 2 volts each. These transformers, switches, &c., are enclosed in a cage of wire netting, and replace smaller transformers formerly used.

The changes in the boiler-house consisted in the provision of a new double-drum Babcock and Wilcox hand-fired water-tube boiler of 16,000 lb. per hour evaporative capacity, fitted with integral superheater, and the moving of one of the existing "economic" boilers about 18 ft. to one side to find room for this. Here, as in the engine-room, no extensions to the buildings were necessary. The alterations to the steam piping were very simple, involving principally an extension of the existing main sectionalised header running behind the boilers parallel to the length of the engine-room. A new Wier steam feed-pump has also been put in. The new boiler arrangements entailed practically no alterations to the existing flues. Messrs. Babcock & Wilcox are the contractors responsible for the new steam and water pipework required.

The load at Eastbourne is, of course, principally lighting, although we understand that there is also a very appreciable load consisting of single-phase motors, to which current is supplied at prices ranging from 2½d. to 1d. per unit, according to the demand. Induction motors are principally used, and these are found to run quite satisfactorily on the 50-cycle circuit. Regarding the latest development in lighting, the Osram lamp, as in many places, is rapidly coming to the fore, and is being to some extent employed for public lighting. Six have been put up in one street, and seven arc lamp-posts have already been provided with 2-arm Osram lamp brackets, while a further 51 are to be similarly equipped. Extensions of business are, no doubt, facilitated by the well-equipped showroom maintained by the Corporation Electricity Department in the town, from which fittings, &c., may be chosen by any consumer, to whom they will be supplied through a wiring contractor.

We wish to express our indebtedness to Mr. J. K. Brydges, Borough Electrical Engineer, to whose specifications the new plant has been supplied and erected, for kindly allowing our representative to inspect the new plant, and putting the information upon which this article is based at our disposal.

ELECTRIC DRIVING IN IRON AND STEEL MILLS

IN a recent contribution to the *Electric Journal* (Pittsburg), Mr. W. Edgar Reed points out that heavy mill work requires a drive capable of standing intermittent and excessive loads, and it is of the greatest importance to have at the same time a very flexible coupling between prime mover and rolls in order to reduce the cost of repairs to a minimum. Electricity offers the most flexible connection known, and is the system best suited to the excessive variations in power required. The variations in power required for a two-high reversing mill may sometimes amount to as much as 3,500 h.p. in a few seconds.

Power for iron and steel mills may be purchased outside or generated at the mills, and is generally derived from water falls, steam, or gas engine-driven electric generators. The waste gases from blast furnaces, when close to the generating station, offer a comparatively cheap source of power. These waste gases are now utilised for this purpose, especially in countries where the cost of fuel is comparatively high. Even in Pennsylvania, where coal is very cheap, it has been found advantageous to use blast furnace gases for the generation of power.

When power for a mill is bought from an outside company, which also furnishes power from its system for other purposes requiring good voltage regulation, large fluctuating loads would be objectionable. The excessive intermittent loads common in mill work, especially if the driving motors in the mills are large compared with the capacity of the power station, may seriously affect the regulation. Under these circumstances the cost of power may be very high unless some method is used to equalise or smooth out the large variations in power. The maximum power required, although it may last for a short time only, determines the maximum size of the complete station and the cost of power. For this reason it is often sold on the basis of the maximum instead of the average or total power consumed. It is therefore very desirable to reduce the maximum

Digitized by Google

demands of peak loads as much as possible in order to secure improved regulation and reduce the cost. The smoothing down of the peak demands will at the same time improve the efficiency of the system by allowing a fairly constant load approximating full-load to be placed on the central station apparatus.

Methods of Equalising.—In the case of continuous mills, when the maximum load lasts but a few seconds, the peak overload may be reduced to satisfactory values by increasing the kinetic energy which the rotating parts give up as the heavy overload comes on. This is accomplished by increasing the flywheel effect by adding weight to the rotating elements or placing a flywheel on the motor shaft, and at the same time designing the motor or control so that the speed drops rapidly as the heavy overloads come on. Increasing the flywheel effect reduces the maximum overload on the motor and line, and by suitable design this overload can be made any desired amount.

When the rolls are to be reversed, the kinetic energy or flywheel effect of the reversing parts should be reduced to a minimum, instead of being increased, as was the case for continuous mills, in order to reduce the energy required in reversing. Some mills are reversed at three second intervals for several passes. The time then increases for succeeding passes. Another method of equalising loads is required for this kind of mill service. One form of equaliser that is suitable for these requirements consists of a motor generator flywheel set connected between the roll-driving motor and the source of power. The general arrangement and connections for such a set are shown in the figure. This system has been found to be very efficient in equalising the large variable and intermittent loads found in large reversing mill work. The system can also be used to good advantage in many cases for driving small mills.

This equaliser set consists of an induction motor with an external resistance in the secondary circuit, driving a flywheel and a direct-current generator. A direct-current motor having

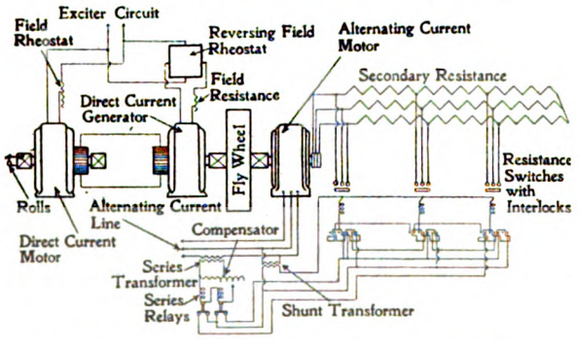

DIAGRAM OF CONNECTIONS, EQUALISER SYSTEM.

drooping speed characteristics could be used in place of the induction motor. The direct-current generator is electrically connected to the roll motor, whose speed and reversing are controlled by regulating or reversing the generator field current. In slowing down the field of the generator is weakened and the roll motor reverses the current through the generator, thus tending to operate the generator as a motor and act as a dynamic brake on the roll motor. Both motor and generator may have auxiliary poles to insure good commutation.

The alternating-current motor is of the wound rotor type, which permits the use of variable resistances in the rotor circuits and the use of a slip regulator for producing a variable speed motor. By the use of this equalising method a nearly constant supply of current may be taken from the line independent of the power being delivered by the roll motor. When the load comes on the direct-current generator, the flywheel gives up energy and supplies that portion of the power required in excess of the average.

In order that a flywheel may give up its kinetic energy when the excessive overloads come on, it is necessary that its speed decrease. The greater the decrease in speed (in a given time), the more energy will be given up, as the kinetic energy in a given wheel is proportional to the square of its speed. This is accomplished by making the speed of the motor automatically adjustable by inserting resistance in the rotor winding, and thus varying the slip. The slip of an induction motor increases with increase of load, but the normal slip is fairly low and the corresponding drop in speed small. The slip is also increased with the increase of rotor resistance.

The efficiency of the induction motor varies inversely as the slip, each per cent. increase in slip meaning approximately one per cent. decrease in efficiency. The slip required of these motors depends upon the value of the peak overload, its duration and interval between peaks, as well as upon the flywheel effect of the rotating parts. It can generally be adjusted for values up to approximately 20 per cent.; a motor having 16 per cent. slip at full load would have approximately 24 per cent. slip at 50 per cent. overload. This 20 per cent. decrease in speed would require the flywheel and all other rotating parts of the set to give up approximately 42 per cent. of their total kinetic energy

Two relays are placed in the circuit which supplies the induction motor. These relays are arranged to change the secondary resistance of the rotor so that the motor may drop in speed as the load increases without drawing a greater current from the line. Both relays are closed when starting or at light loads. As the speed increases the resistance switches are closed by the rotor current, first one, then two, three, four, &c., until the current in the induction motor reaches the desired maximum, when the first relay opens the auxiliary circuit so that no more switches can close. When a heavy load comes on the flywheel gives out energy and slows down, allowing more current to be taken from the line. This causes the second relay to operate and cause the resistance switches to insert more resistance in proper order again. This adjustment forces the flywheel instead of the motor to take the greater part of the intermittent load by giving up part of its kinetic energy, which was stored up before the overload came on. This equalises the irregularities and gives a fairly constant load on the induction motor and all other apparatus back of it; makes an exceedingly flexible connection between prime mover and load, and procures good voltage regulation of line. This is essential when light and some other kinds of apparatus are operated on the same circuit as the motors and the conditions of motors operating auxiliary apparatus is also much improved, as a drop in voltage means a reduction of the starting and pull-out torques of shunt and compound-wound direct-current motors or induction motors. The torque and output of an induction motor varies as the square of the applied voltage, hence a 10 per cent. reduction in voltage would therefore mean approximately 20 per cent. reduction in maximum starting and pull-out torque.

If power is bought outside, such a system would certainly be required, and it is also advantageous where power is generated by the mill company. Some idea of the importance of such a system can be seen from an installation which required 4,000 horse-power in driving motors and only 1,400 horse-power approximately in the motor of the equaliser set and all apparatus back of it, including the transmission line, switchboard, instruments, electric generator, engines, boilers, and fuel.

Continuous Mill.—Among the many installations that have been made recently is the following:—Two 1,500 horse-power, compound-wound, 220-volt, 100–125 r.p.m., direct-current motors at the Edgar Thomson Steel Works, for driving continuous rail mills. These motors are direct-connected to the rolls. Special attention has been given to the mechanical design. The bearings are of the oil ring and forced circulation babbit lined type, 25 in. in diameter and 62 in. long. They are also arranged for water cooling. The motor is also very liberally designed and commutation is exceedingly good. A 125,000 pound cast steel segmental flywheel, 18 ft. in diameter, is mounted on the motor shaft to assist in equalising the load on the motor and power house. The speed of the motor drops from approximately 125 to 90 r.p.m. in actual operation, which allows the flywheel to take care of the peak loads.

Reversing Mills.—Installation at the Hildegarde Works (Austrian Silesia).—This mill is for rolling two-ton ingots down to billets for making girders, rail, &c., and for the first passes should reverse every six to eight seconds. The mill is driven by a four bearing set of three direct-current motors. These motors are connected together by two rigid couplings and are divided into three units in order to keep the inertia of the rotating parts as low as possible as well as for manufacturing advantages. The normal rating of each motor is 1,200 horse-power at 330 volts, and speeds obtained are from 0 to 120 r.p.m. The maximum horse-power of each motor is 3,000, which makes 9,000 horse-power maximum for operating the ingot mill. The motors have series and shunt separately excited windings, and the armatures are connected in series.

The equaliser is a four bearing set consisting of an induction motor, two direct-current generators, and two flywheels, and runs at 375 to 310 r.p.m. The flywheels are made of cast steel, are 13 ft. in diameter, and each one weighs about 26 tons. Water-cooled brakes are mounted on the wheels for stopping the set quickly in case of necessity. The two direct-current generators and the three mill motors are connected permanently in series, the mill motors being controlled and reversed by the field current of the generators. This control is easily and quickly operated. When reversing the set acts as a brake for the mill motors, and energy is returned to the equaliser set. The speed of the induction motor is controlled automatically by inserting the resistance of a water rheostat in the rotor circuit.

The power taken from the generating station does not exceed

Digitized by Google

25 per cent. of the maximum power required for operating the mill.

Installation at the Illinois Steel Works.—This 30-in. two-high plate mill is driven by two 2,000 horse-power, 575 volt normal rating direct-current shunt-wound motors mounted on a common shaft. The speed varies from 0 to 150 r.p.m. The mill should be capable of reversing every four to six seconds. Good commutation is secured at low voltages, and heavy currents by the use of commutating poles and compensating coils wound in slots in the pole faces. The power taken from the generating station is approximately 30 per cent. of the maximum power taken by the mill motor.

ELECTROCHEMISTRY AND ELECTRO-METALLURGY

THE Norsk Hydroelektrisk Kvaelstof Co. of Notodden is now working in conjunction with the Badischen Anilin- und Soda-Fabrik, of Ludwigshafen, in connection with the manufacture of calcium nitrate from the atmosphere, by the Berkeland-Eyde system. They are now completing a new power station at Svaelgios, capable of delivering 47,000 h.p. The energy is obtained from water power, the water flowing from the dam through a canal and tunnel a distance of about 650 metres (715 yards), the rate of flow being about 100 cubic metres (3,530 cubic feet) per second. Owing to the turbine house being built in an exceedingly narrow, rocky gorge, the water is led to the turbines by means of perpendicular tunnels cut through the rocks, instead of, as is usual, by means of pipes. The turbines, which are from 10 to 12,000 h.p., are directly coupled with the dynamos. These turbines, which are said to be the largest and most powerful in Europe, have been built by J. M. Voith, of Heidenheim. It is hoped very shortly to have the plant in operation. Other works, to give even greater power for the fixation of atmosphere, are already projected, and in time it is expected that a great part of the water power of Norway will be utilised for the manufacture of artificial nitrogenous fertilisers.

An abstract of a Paper upon "Electric Zinc Smelting," by F. T. Snyder, is given in *Electrochemical and Metallurgical Industry* of December. The comparative cost of the smelting in two plants each of 25,000 tons annual capacity is given. The first cost for plant in each case is about the same, viz., rather over £100,000. The salaries and general operating costs, depreciation, and so on, are practically the same. The cost of working a modern retort plant in which coal is burnt is about 16s. per ton of raw material. The labour on an electric plant can be kept below 12s., because of the greater compactness of the plant. When retorts are employed it is necessary to give a very thorough previous roasting to remove the sulphur, with the electric stack furnace practically as good results are given with ores containing 6 per cent. of sulphur as with those containing only 1 per cent. A retort plant will consume 4,200 lb. of coal per ton of raw ore, 600 lb. being used in roasting. But with the electric stack furnace 1,200 electrical horse-power hours are required per ton, which represents a consumption of 1,800 lb. of coal; also the coal required for roasting is only about one-half. Consequently about one ton of coal per ton of ore is saved.

With the retort plant 800 lb. of reducing material will be used per ton of ore; with the electric stack furnace about 200 lb. The renewal of retorts is calculated by the author to be about 1s. 8d. per ton of ore; this is, of course, saved in the stack plant, but the consumption of electrodes will cost about 10d. per ton. A summing up of these differences shows a saving of about 10s. per ton of ore operated upon by the electrical method. But a further saving of over 15s. per ton is obtained by the increased recovery of zinc with the stack plant.

With the electric stack plant, a certain quantity of iron in the zinc ore is an advantage. Up to a point where the iron percentage is equal to one-half of the silica percentage, iron is not only required but must be added if not present in the ore. Lead in the ore is reduced, and can be separately collected, consequently it is not necessary to so thoroughly concentrate the ore as when the retorts are employed. With zinc concentrates containing 3 per cent. of lead, 50 lb. per ton of raw ore, or 2½ per cent. will be saved in the electric retort furnace, but lost in retort smelting. The author finally concludes that these and other savings will save practically £2 per ton upon the zinc produced if the electric furnace be employed.

L'Industrie Electrique of October 25th describes the method of Theirot and Nougier for obtaining tin from tin-scrap and tin residues. In the first place, the tin is heated with sodium hydroxide and converted into sodium stannate. Copper and lead and other impurities are then removed, and the pure sodium stannate solution is electrolysed with iron anodes and cathodes of tin. With a current density of 300 to 400 amperes per square meter, and at a temperature of 80 to 90° C., a solid and reguline deposit of tin is obtained. The electrical pressure at the electrodes is 2·4 volts. In order to obtain satisfactory results it is found advantageous to thoroughly circulate the electrolyte and to keep the solution at a definite concentration.

According to *Electrochemical and Metallurgical Industry* of December, the Norton Co., of Worcester, Mass., are manufacturing a new abrasive called alundum. This substance consists of purified bauxite, which is first heated in calciners, to drive off water, and is then melted in an electric furnace at a temperature of 2,700° to 3,300° C. The electric furnace plant employed is situated at Niagara Falls. The alundum is worked into grinding wheels, and various sharpening stones. It is claimed that alundum is an abrasive of great sharpness and of great hardness, and is absolutely uniform.

E. D. Chaplin, in his American Patent 871,161 (1907), describes a process for the electrolytic production of white lead. A cell with three compartments is used, a solution of sodium nitrate and sodium chlorate being supplied to the middle compartment. The solution in this compartment is kept a little above the level of the solution in the other two compartments, in order to prevent mixing of the anode and cathode solutions. The anode is of lead and the cathode of copper. At the anode lead nitrate is in the first place produced, and then this is supposed to be converted into lead oxychloride, which is soluble in the electrolyte, which is kept at an elevated temperature by means of steam coils. The sodium hydroxide produced at the cathode is converted into carbonate in a separate tank by passing carbon dioxide into it. The two solutions are then mixed and the precipitate white lead filtered off, the same electrolyte being used over again.

Mr. Chaplin also has a second Patent 871,162 (1907), dealing with the preparation of chrome yellow. In this case the first part of the proceeding, that is, the electrolysis, is the same as in the preceding case. But the sodium hydroxide is mixed with chrome alum in sufficient quantities to re-dissolve the chromic hydroxide, which is first precipitated. This solution is then mixed with sodium chloride, and electrolysed in an anode compartment. By this means the chromic solution is oxidised to chromate. On now mixing the lead oxychloride solution with the chromate, a precipitate of chrome yellow is obtained.

ELECTRIC TRACTION IN THE CASCADE TUNNEL

Three-phase Locomotives

THE announcement was made in ELECTRICAL ENGINEERING, Vol. I., page 945, that three-phase locomotives were to be adopted by the Great Northern Railway Co. of America for service in the Cascade Tunnel. Some further particulars of the locomotives in question, which are now under construction by the General Electric Co., are given in the *Street Railway Journal* (New York).

The tunnel is approximately 2¾ miles in length, with no ventilating shaft, and a uniform grade east of 1·6 per cent. in the tunnel section, making the difficulties of ventilation with steam locomotive operation very serious. Apart from danger of poisonous gases of combustion, the interior of the tunnel has become so fouled with soot as to reduce the tractive effort of the steam locomotives now used, by reason of the slippery condition of the rails.

The locomotives will weigh 100 tons each, with all the weight on the drivers. Each locomotive will be equipped with four three-phase induction motors of 325 h.p. capacity, mounted on two articulated bogie trucks, and each machine will have a capacity of hauling a 500-ton train load up a 2 per cent. grade at 15 miles per hour, and, as the motors are reversible, the speed of the train can be controlled down grade by regeneration. It is hoped by this means to introduce an additional feature of safety, and eliminate the possibility of breakdown due to overheated wheel tyres and brake shoes.

The locomotives will receive their supply from two 6,600-volt conductors fed from a step-down transformer station located at the entrance of the tunnel. The generating station will be located on the Wenatchee River, 30 miles from the tunnel, and power will be transmitted over duplicate transmission lines at thirty-three thousand volts. The generating station will contain two 2,000-kw. three-phase water-wheel-driven generators operating at 25 cycles, and arrangements are being made to take care of excess power of regeneration due to an unbalanced load up and down grade. The entire installation is expected to be ready in about one year, and work is already well under way on the water-power development, as well as the electrical apparatus.

Institution of Electrical Engineers: Manchester Section.—The meeting which was announced for Tuesday last, and at which Mr. G. W. Worrall's Paper on "Magnetic Oscillations in Alternators," was to have been read, was postponed, and will take place next Tuesday, January 14th, at 7.30 p.m., in the University (Physical Laboratory), Manchester.

ELECTRICAL SCIENCE

British and American

An Unknown Gas from Aluminium Electrodes.—When cathode rays are generated by an influence machine in a vacuum tube containing a pure gas, the relation between the pressure, p, of the gas and the discharge potential, V, can be represented by p^2V = constant. This relation is independent of the current, but does not hold at all in gaseous mixtures. During the passage of the discharge a gas is continuously evolved from the electrodes, if these are of aluminium, which gradually renders the original gas impure, so that the above relation ceases to hold. If the tube is kept on the pump so as to maintain the pressure within the range required for the production of cathode rays, then after the discharge has passed several hours, the value of p^2V again becomes a constant. But the value of this constant is the same whatever gas originally filled the tube, and is about one-quarter of the constant given by a new tube filled with hydrogen. In the December *Philosophical Magazine*, R. v. Hirsch and F. Soddy examine into the nature of the gas evolved from the electrodes. The known dependence of the constant value of p^2V on the molecular weight had already suggested that the gas has a molecular weight 4, so the observers carefully sought for helium spectroscopically and electrically. The only positive indication, reached after many experiments, was found in the fact that English bulbs showed a marked absorption under conditions in which German bulbs were generating the unknown gas. This difference was traced to the electrodes, and English electrodes in a German bulb gave off no gas. The authors suggest that the presence of sodium in the German aluminium may play an indirect part in the phenomenon. The presence of a trace of sodium in aluminium renders it, as is well known, capable of decomposing water, so that an electrode of such metal, by mere exposure to the air, may become charged with hydrogen probably chemically combined as hydride. The authors venture the opinion that the unknown gas may be a modification of hydrogen just as ozone is a modification of oxygen, and capable of withstanding the discharge of an influence machine. The discharge of an inductorium may decompose it, and thus can be explained the fact that the hydrogen spectrum always appears in the final stages.

Clark and Weston Standard Cells.—In the December issue of the *Bulletin* of the Washington Bureau of Standards, F. A. Wolff and C. E. Waters set out in full detail the results of a prolonged study of the Clark and the Weston cells. Their investigations relate principally to the effect on the E.M.F. of a cell, of the mode of preparation and purification of the materials. For example, the mercurous sulphate used in making the cells was prepared, severally, by electrolysis in two different types of apparatus, by the action of fuming sulphuric acid on mercury, by the reaction between sulphuric acid and mercurous nitrate, by the action on mercury of dilute solution of nitric acid in sudphuric acid, by the reduction of mercuric sulphate by mercury, by the reduction of mercuric sulphate by sulphurous acid, by the recrystallisation of commercial mercurous sulphate from sulphuric acid, and by various modes of digesting commercial mercurous sulphate in sulphuric acid. The most satisfactory cells were obtained when grey samples of mercurous sulphate prepared by the electrolytic process were used. Among the cells made with the chemically-prepared samples of sulphate, those containing the samples obtained by reducing mercuric sulphate with sulphurous acid were the worst. But practically any method of preparation can be made to yield good results in respect of final E.M.F. The remaining materials used in the construction of standard cells can, it is shown, easily be obtained exceedingly pure; and, besides, the usual impurities, even if present in relatively large quantity, exert practically no influence on the E.M.F., not more than two or three parts in 100,000. Moreover, the authors find that the size of grain of the constituents has no appreciable effect, and the tables they give prove that, once set up, the cells keep a very constant E.M.F. for at least a year. Since the labour of preparing the materials is much greater than the work of setting up the cells, the authors propose that materials of standard purity should be furnished by the various national physical laboratories, so that standard cells could be set up quickly by the private investigator, and used with confidence as a fundamental electrical standard. In the opinion of the authors, the standard cell is to be preferred to the silver voltameter (which they designate "coulometer"), not only because of the now undoubted reproducibility of the standard cell, but also because nearly all voltage and current measurements of precision are made by the potentiometer directly in terms of the E.M.F. of the standard cell, or in terms of that E.M.F. and a standard resistance.

Continental

Efficiency of the Telephone.—F. H. Abraham and Devaux Charbonnel give, in the *Comptes rendus* for December 23rd, some instructions concerning the most efficient arrangement of telephone lines. For a given sound, the microphone behaves as an alternator without inductance, having an internal resistance of about 10 ohms. If the line is very long, it may be regarded as an ohmic resistance R, of the order of 500 ohms, in series with a capacity C of a fraction of a microfarnd. At the receiver, the line acts as an alternator, having these same characteristic constants, R and C, and an E.M.F. amounting to a definite fraction of the E.M.F. supplied. These assumptions may be made the basis of a complete theory of the transmission of a musical note along a very long telephone line. The authors specify the conditions which make for the loudest rendering. For every type of receiver the diameter of the wire must be such that the resistance of each of the two receivers shall be a little higher than one-quarter of the apparent ohmic line resistance R. In practice, this means choosing receivers with a resistance of about 100 ohms. If M is the internal resistance of the microphone, the most favourable transforming ratio is a little higher than $\sqrt{R/2M}$.

In practice, this means a transforming ratio of 6 or 7. The impedance of the thin wire of the transformer must be decidedly greater than the apparent line resistance R. The above conditions are usually observed in good commercial circuits. As regards the efficiency of commercial telephone transformers, the authors find that to be less than 60 per cent. these are, in fact, too small. An efficiency of 90 per cent. should be easily attainable without making the transformers too costly or too cumbrous. The authors give the following dimensions as a model :—Length, 17 cm.; external diameter, 3 cm.; total section of iron wires, 0·3 sq. cm.; turns of thick wire, 550; turns of thin wire, 3,300; diameter of thick wire, 1·1 mm.; diameter of thin wire, 0·4 mm.; resistance of thick wire, 0·9 ohm; resistance of thin wire, 24 ohms.; and inductance of the same, 0·4 henry. Too much must not, however, be expected from this improvement, as the ear is not very sensitive to loudness, an increase of 50 per cent. being barely distinguishable. The improvement of the microphone offers a much more promising field, and the authors believe that all existing types are capable of great improvement.

X-ray Test for Death.—Charles Vaillant presented a note to the French Academy on November 18th last, announcing that the radiography of the stomach and the large intestine furnished a conclusive test for death. He alleged that these organs, being arrested in their otherwise incessant motion, and being also filled with gaseous sulphides, which become phosphorescent under the action of X-rays, become clearly visible in all their detail on the radiograph. Some additional material on this important subject is furnished in the *Comptes rendus* for December 23rd by M. Béclère, who, however, points out that such radiographs cannot be relied upon in every case. When the breathing action is suspended, for instance, it is quite possible to obtain sharp detail on radiographs of the lungs. The stomach may also be clearly delineated when it is filled with any kind of gas, as with carbonic acid evolved on swallowing bicarbonate of soda and tartaric acid. On the other hand, the perishable motions of the intestines often continue for some time after death. The distinction is not one between rest and motion. It is merely a distinction of degree. The alleged tests of death may be simulated by a comparative immobility of the intestines accompanying the cessation of breath, or even by its paralytic immobility.

The Electricity Supply Bill.—The Incorporated Municipal Electrical Association has sent a circular letter to various municipal bodies enclosing a copy of the following resolution, which has been adopted by the Association :—"That the Association urges the Board of Trade to reintroduce the Electricity Supply Bill during the coming Session, and exercise every means to have the same passed into law." The municipal bodies are requested to bring the matter under the notice of their local Parliamentary representatives with a view to obtaining their co-operation to bring about the desired result.

Electric Power Supply in Essex.—The Town Clerk of Colchester has sent a circular letter to the municipalities affected, calling attention to certain provisions in reference to the supply of electrical energy, sought to be obtained by the Great Eastern Railway Co. under the General Powers Bill they are promoting for the ensuing session of Parliament. The Electricity Supply Committee of Colchester are of opinion that the interests of authorities possessing powers of electrical supply may be seriously affected by the proposed measure, and the various Town Councils are urged to oppose the Bill. We give the clause objected to below :—"19.—(1) It shall be lawful for the company from their works at Parkeston or elsewhere to supply either in bulk or otherwise electrical energy not required for their own purposes to any tenants of the company or occupiers of premises connected by siding with any railways of or leased to or worked by the company and to any local or sanitary authority or to any company authorised to supply electrical energy and any such authority or company may take such electrical energy from the company notwithstanding anything in any Act or Order authorising such authority or company to supply electrical energy. (2) The company on the one hand and any such tenants occupiers authority or company on the other hand may enter into and carry into effect agreements with reference to any such supply of electrical energy by the company and the rents or sums of money to be paid or other consideration to be given in respect of such supply. (3) The company may recover any rents of sums of money from time to time payable in respect of any such supply of electrical energy summarily."

THE AMERICAN WESTINGHOUSE COMPANIES

ACCORDING to the *Electrical World* (New York), Messrs. Haskins & Sells, certified public accountants, in compliance with the request of the receivers, have made an audit of the books and accounts of the Westinghouse Electric & Manufacturing Co., which was made public after the meeting of the creditors. The consolidated and condensed statement of income of the Westinghouse Electric & Manufacturing Co., and subsidiary manufacturing companies in the United States, shows a balance available for the payment of interest and dividends for the seven financial years ended March 31st, 1907, and for the seven months ended October 31st, 1907, as follows :—

	7 mos. ended Oct. 31, 1907.	Total for 7 years and 7 mos. ended Oct. 31, 1907.	Average per annum for 7 years and 7 mos. ended Oct. 31, 1907.
Sales	$22,265,322	$181,723,643	$23,963,557
Cost of sales	19,334,540	154,411,675	20,361,979
Net earnings ...	$2,930,782	$27,311,968	$3,601,578
Other income	869,833	5,328,929	702,716
Total income	$3,800,615	$32,640,987	$4,304,294
Inventory adjustments, &c.	717,393	3,951,961	521,137
Net income applicable to int. and div'ds	$3,083,222	$28,688,936	$3,783,157

The credits made to the company's surplus account during the seven years and seven months ended October 31st, 1907, which are not included in the statement of earning and expenses, because they cannot be considered as income applicable to the payment of interest and dividends, being of an extraordinary and unusual nature, and not dependent upon the regular operations of the business, are as follows :—

Premium on capital stock sold during the period ...	$5,884,150
Profit on stocks and bonds sold during the period ...	1,465,890
Profit on real estate sold	84,200
Profit on exchange of assenting capital stock for non-assenting capital stock under terms of reorganisation of 1892	2,357
Unclaimed dividends	126
Profit through adjustment of Sawyer-Man Electric Co. accounts previously charged off (prior to the year 1901)	143,987
Miscellaneous	67,516
Total	$7,648,247

The charges made by the company against its surplus account for items of an extraordinary nature, which were not applicable to the income, prior to determining the amount available for interest and dividends, and which are not included in the income statement, have been as follows :—

Interest	$6,682,414
Dividends on stock	14,384,632
Depreciation of sundry stocks and bonds, consisting principally of stock of Consolidated Electric Light Co., U.S. Electric Lighting Co., Multiphase Motor Co., Electro Magnetic Traction Co., and Manhattan General Construction Co.	1,290,177
Amount charged off in connection with closing up the Walker Co. matters	981,056
Special charges for depreciation in addition to those included in the operating expenses	897,876
Premiums and commissions on debenture certificates purchased	45.535
Amount paid Westinghouse Glass Co. for purchase of lease of property required by Allegheny Foundry ...	12.234
Fire loss, Chicago stock	18.219
State tax on increase of capital stock	25,111
N.Y. Stock Exchange fee for increase capital stock ...	650
Services of Trust Co. in connection with capital stock Consolidated Electric Lighting Co.	500
Cost of moving lamp factory from Pittsburg to New York	100.161
Devising and installing accounting system	52.000
Commissions on issues of capital obligations	780,000
Legal services and expenses in connection with the issue of capital obligations	14.418
Discount on ten-year collateral note	202.703
Discount on convertible bonds charged off	158,333
Amount paid Geo. Westinghouse for payments made in the interest of the company to various officers, engineers, and other employees of Electric Company, in addition to their regular salaries paid by the company during last 10 or 12 years	400.000
Miscellaneous	45.058
Total	$26,091,079

The increase in the surplus account of the Westinghouse Electric & Manufacturing Co. and subsidiary manufacturing companies in the United States during the seven years and seven months ended October 31st, 1907, has amounted to $10,246,104, as follows :—

Net income available for interest and dividends ...	$28,688,936
Other profit and loss credits	7,648,247
Total credits	$36,337,183
Charges made against surplus account	26.091,079
Balance, being the increase in the surplus account ...	$10,246,104

The creditors and stockholders of the Westinghouse Electric & Manufacturing Co., who have been working out the details of the plan for raising new capital and restoring the company to its stockholders, after a long conference last week announced the organisation of a committee of creditors, of which James N. Jarvie, representing the National Bank of Commerce and other financial institutions, was made chairman. The committee comprises Richard Delafield, President of the National Park Bank; James N. Jarvie, representing the National Bank of Commerce and other financial institutions; Albert H. Wiggin, Vice-President Chase National Bank; F. H. Skelding, President of the First National Bank of Pittsburg; Charles A. Moore, of Manning, Maxwell & Moore; Neal Rantoul, of F. S. Moseley & Co., of Boston. A seventh member residing in Chicago is to be added.

CORRESPONDENCE

To the Editor of ELECTRICAL ENGINEERING.

SIR,—My attention has been called to some observations in the December issue of the *Engineering Review* on "Live Steam Feed Heating," by Mr. Wm. Paterson, in which he states that there "has been quite a resurrection of appliances for live steam heating," but he "is doubtful as to the economy resulting from such apparatus in every day working." Mr. Paterson then goes on to state that these appliances are not new, and states that a reference to the Patent Office records will prove this. Finally, he winds up by extolling the virtues of exhaust feed water heating and purifying plant.

That the latter class of plant is, under certain conditions, both useful and economical I can testify after long experience. When, however, he advocates this system at the expense of damning live steam heating, which, when properly applied, is capable of furnishing as great or greater economies than the former plant, I, as an interested party, am compelled to join issue with him. Further, live steam heating of the feed can and does furnish an economy which is superimposed upon economies capable of attainment either by Mr. Paterson's apparatus or by improved combustion, or by both.

None of the obsolete forms of live steam heaters, and very few of the modern types of live steam heaters furnish to the boilers water which is hot enough to give good economy. This economy goes up with great rapidity with the last few degrees increment of heat, bringing the feed water quite up to the temperature of the steam, hence the importance of employing an internal heater, which will give full steam temperature to the feed water, and at the same time furnish drier steam from the boiler.

There is no subject in connection with boiler-house plant upon which there are wider or more emphatic differences of opinion between engineers than as to the economy or otherwise of using live steam-heated feed water for boiler feeding purposes, the reason being that the subject is very imperfectly understood, and there are numbers of manufacturers selling live steam heaters who are evidently not conversant with the conditions necessary to produce economical results. In numbers of cases live steam heaters are at work ostensibly for the purpose of economising coal, but as a matter of fact they are entailing a heavier consumption of fuel than would be required were the boilers minus the live steam heaters.

Live steam heating under certain circumstances substantially economises coal and greatly increases the output of steam for the boilers, but there are distinct limitations to the economy which can be obtained, and it is important that all steam users contemplating the adoption of such apparatus should seek competent advice on the matter, otherwise after having spent their money they may find that their consumption of coal, instead of decreasing, has increased. In view of the present high prices and prospective increasing cost of fuel, it is a matter of considerable importance that manufacturers and steam users who are wise enough to avail themselves of every economy, should be carefully advised in this matter, or they may increase their coal bill and entirely miss the substantial economies and lessened fuel cost which live steam heaters are capable of producing.

Believe me,
Yours faithfully,
G. WILKINSON.

HARROGATE, *Jan. 4th*, 1908.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 27th

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

1906 Patents

28,793, BABB, CHAPMAN & COCKSHOTT. An improved method of braking on electric railways, tramways, or other machinery driven by electric motors to get rid of the uncertainty of action due to dirty commutators and faulty contacts and connections with the ordinary rheostatic methods. An additional circuit, either electrically distinct from, or in connection with, the ordinary braking circuit, or with a re-arranged braking circuit is provided, which derives its current from the same source as the driving motor or some auxiliary force. The additional circuits are arranged so that the current from this source shall pass through the fields of the motors, or through the whole motors acting as generators, in the same direction as the current would flow in ordinary braking motors, and by providing auxiliary windings on the fields of the motors. The current may be allowed to continue flowing in the circuit throughout the whole range of the braking operations, or can be discontinued at any point by temporarily connecting up the motor fields, and passing through them a current of suitable value. The necessary connections are made on the existing controllers, so arranged that the necessary contacts are made by means of switches, quite apart from the ordinary controller, but operated by movements of it. Three claims, three figures.

1907 Patents

316, A. L. RHODES & RHODES ELECTRICAL MANUFACTURING CO., LTD. Instead of using solid, wedge-shaped rings for holding commutator segments in their positions, the present patent, a ring of bent sheet steel, is used, so that the weight of these parts is considerably reduced. The ring may or may not be in two or more pieces, and is fitted with back plates, which lie against the two free edges of the ring, and receive pressure from annular nuts, which are screwed upon the main casting of the commutator. Two claims, one figure.

2,227, SIEMENS BROS. DYNAMO WORKS, LTD. A time-limit device for circuit-breakers, in which a train of wheels governed by a fly regulator is connected with the plunger of the circuit-breaker, so that if it commences to move under the action of an ordinary overload, it will throw the train of wheels into motion, and will not be released, and allowed to complete its motion, and work the main switch until the wheels have completed a certain number of revolutions, and the interval in which they do this will be shorter as the overload is greater. The connection of the train of wheels is made through a suitable friction coupling device, capable of being regulated to slip more or less easily, and is set so that if the overload should be excessive, the pull of the plunger will be so sudden that it will slip at once, and allow the circuit-breaker to act instantaneously. Four claims, five figures.

16,514, P. MACGAHAN. This invention provides a device for automatically connecting an alternating current dynamo to an alternating current supply circuit when the electro-motive forces of the two circuits agree in phase and frequency. The connection of the machine circuit is effected by means of two electro-magnets, each provided with two windings, adapted to be connected respectively to the alternating circuit, and the machine, the windings of one electro-magnet being arranged to act in conjunction with one another, and those of the other electro-magnet to act in opposition to one another when the currents in the windings agree in phase. The circuits of the actuating windings are so arranged and simplified that auxiliary transformers are dispensed with, and no direct connection exists between the machine and the circuit to which it is to be connected. Two claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-morrow, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

22,500, COLLYER. Earthing and protecting electric conductors.
25,009, BRITISH THOMSON-HOUSTON CO. & DALTON. Arc Lamps.
26,066, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Trucks for electrically-propelled vehicles.
27,520, KANDO. Control of multiphase motors.
28,559, LOCKETT. Tramcar brakes.
28,503, BONINE. Method of controlling dynamo-electric machines and apparatus therefor.
28,579, CHLORIDE ELECTRICAL STORAGE CO. & HEAP. Lid bolt for storage battery boxes and the like.
28,634, COLLIE. Apparatus for indicating the magnitude of torque or turning effort in shafting.
28,830, HAYWOOD, & MCKENZIE & HOLLAND, LTD. Electric treadles or rail deflection contact makers for railway signalling and the like.
29,019, GRÖNDAL KJELLIN CO. & HÄRDÉN. Induction furnaces.
29,072, BROWN. Electrically-operated railway and like signals.
29,120, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric heaters for fluids.
29,300, COWPER-COLES. Electro-deposition of iron.

1907 Patents

97, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Protective devices for electric transmission systems.
829, MORISON. Apparatus for separating oil from feed-water.
1,197A, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Treatment of refractory materials by electricity.
1,348, ELECTRIC IGNITION CO. & HALL. Insulation of dynamo armatures.
1,587, LAKE (*Kellogg Switchboard Supply Co.*). Party line telephone systems and apparatus therefor.
3,078, NOBBS & NOBBS. Electric steam radiator for heating buildings or the like.
3,214, HOOKHAM & SPRAGUE. Counting trains for electricity meters and the like.
3,278, BARNETT. Electric distributors for use in internal-combustion engines.
4,338, AUSTIN. Receivers for wireless and other telegraphy.
4,801, POULSEN. Receivers for wireless signalling.
5,155, ALBION MOTOR CAR CO. & MURRAY. Magneto-electric generators.
5,574, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Insulating material and processes for making the same.
5,904, FOSTER. Electric measuring and recording instruments of the thermal type.
7,800, GOODMAN & ACKLAND. Conduits for electrical cables and wires.
9,463, NORTH & POHL. Electrolytic electricity meters.
10,369, ATELIERS THOMSON-HOUSTON. Commutation of dynamo-electric machines.
12,860, RIVERS-MOORE & DONALD. Contact or commutator for dynamo-electric machines.
13,021, WOODHOUSE. Brush-holders and carriers for electric generators and motors.
13,259, HICKLEY. Brush holders for dynamos and motors.
15,017, KUZEL. Metallic filament lamps.
15,769, BEECHER. Electrical railway systems.
16,098, COWPER-COLES. Apparatus for electro-plating.
17,492, FINLAY. Anode for electrolysis.
18,020, LUNDBERG, LUNDBERG, & LUNDBERG. Electrical switches.
18,082, SZEK. Carbon-electrodes.
18,398, BIEWEND. Manufacture of steel and electro-metallurgical induction furnaces for use therein.
22,612, KJELLBERG. Electric switches.

The following complete Specifications are open to Public Inspection at the Patent Office, but are not yet published for sale.

1907 Patents

11,594A, ALLGEMEINE ELEKTRICITÄTS-GES. Electric motors specially adapted for rolling mills.
19,340, SIEMENS & HALSKE AKT.-GES. Signalling telegraphs.
27,744, ALLGEMEINE ELEKTRICITÄTS-GES. Signalling systems and control systems for mines and the like.

Amended Patent

8,680. 1904. THE BRITISH THOMSON-HOUSTON CO. have obtained leave to amend this specification, by the addition of the following paragraph: "It has hitherto been proposed to electrically work reciprocating machines by apparatus consisting of a reversing switch, and starting switch, operated from reciprocating mechanism, and circuits controlled by the switches by which the motor is worked at suitable speeds on the cutting stroke of the tool, in such machines, as planes, &c., and retarded and reversed, worked at a maximum speed on the return stroke of the tool, retarded and again reversed, the reversal and restarting in each case being made in a strong magnetic field, and the speed acceleration on the return stroke effected by weakening the shunt field of the motor by the introduction of resistances in the field circuit."

LOCAL NOTES

ARBROATH: *Electric Lighting Station.*—The plans presented by Mr. G. Balfour, electrical engineer, of London, for the erection of the electric lighting station, were formally passed by the Dean of Guild Court on the 6th inst. The scheme is for electric lighting and power for the town. The station will be built at South Grimsby.

BELFAST: *Cavehill and Whitewell Tramways.*—At the monthly meeting of the Council on Wednesday, January 1st, when the resolutions passed at the meeting of December 2nd were confirmed "That a Bill to confirm the agreement, dated May 1st, 1907, and made between the Cavehill and Whitewell Tramway Company of the one part, and the Lord Mayor, aldermen, and citizens of the city of Belfast of the other part, for the purchase of the tramway of the company and their lands of Drumnadrough, County Antrim, also to wind up the said company, be promoted in the ensuing Session of Parliament, and that the expenses attending the promotion of such Bill shall be defrayed out of the General Purposes Fund or rate." The resolution was put to the meeting and carried.

The Electricity Accounts Audit.—At the weekly meeting of the Tramways and Electrical Committee on the 6th inst.—Sir Robert Anderson presiding—the City Surveyor, Mr. Cutler, submitted a voluminous report dealing with the alleged inaccuracies brought forward by the Citizens' Association in connection with the conversion of the tramway system, and the alleged overpayment of sums of £661 11s., £5,670, £277 7s. 4d., £2,218 10s., £1,417 13s. 3d., £7,390, £5,518, £2,931, and £12,000, in connection with various parts of the work. The committee decided to postpone the consideration of the matter for a fortnight. It may be recalled that the Corporation expressed itself confident in Mr. Cutler's figures when the matter was brought before it.

BIRMINGHAM: *Tramway Receipts.*—The traffic returns of the public tramways for the week ending December 28th, as compared with those for the preceding week, are as follows:—December 28th, receipts, £6,172; passengers, 1,547,991; December 21st. receipts, £6,099; passengers, 1,587,905; or an increase of £73 and a decrease of 39,944 passengers. The figures for the whole year of working are not yet entire, as the tramways only passed into the control of the Corporation a year ago from the British Electric Traction Co. In 51 weeks and five days covered by the returns to hand, 71,645,112 passengers have been carried, and the receipts amount to nearly £284,000, giving a weekly average of 1,400,000, and receipts of over £5,000. Taking the working costs at 6½d. per car mile, and the earning at 9d. per car mile, which figure has been exceeded on several weeks of the year, the profits earned should be well over £50,000 for the twelve months.

BLACKBURN: *Light Railway Order.*—The Blackburn Town Council, on January 3rd, instructed their Town Clerk to take necessary proceedings to oppose the application of the promoters of the Blackburn, Whalley, and Padiham Light Railways for a revival and extension of time of their order.

BURY: *Electricity Station Extensions.*—The Bury Town Council, at a meeting held on January 2nd, decided that the Electricity Committee should be empowered to proceed with the preliminary arrangements for carrying out the necessary extensions at Chamber Hall, including provisional acquisition of land and railway siding accommodation, and for application to the Local Government Board for sanction to borrow the necessary money to carry out the extensions. The proposal is to build a new generating station on the high-tension alternating system. This has been necessitated by the large demands made locally for power to drive the textile factories. As the plant at the existing station is now worked at its full capacity, it has been decided that instead of extending the present station, which does not provide sufficient facilities for coaling, and for condensing water, a new site with a railway siding and adequate provision for condensing water has been obtained at Chamber Hall from the Earl of Derby.

COBHAM: *Proposed Electricity Supply.*—Owing to the gas in Cobham being 5s. per 1,000 ft., the Parish Council has never adopted the Public Lighting Act, and the streets have never been lighted by artificial means. The Woking Electric Supply Co. is seeking a Provisional Order to install electric light in the village, and is prepared to tender for the lighting of the streets, and to supply light for other purposes at 6d. per unit.

DUBLIN: *Electricity Accounts.*—The Lighting Committee of the Dublin Corporation have issued a report of the progress of their undertaking for the year ended March 31st, 1907. The gross amount received was £44,225, of which £10,736 was credited to the electricity accounts for the cost of public lighting, and the balance of £33,849 was from private consumers, rentals of meters, and work done for the Corporation, &c. The total expenditure chargeable against the gross income was £22,029, leaving a gross profit of £22,196. £216 is to be deducted from this, being amounts written off accounts and interest paid on consumers' deposits. The balance was devoted to the repayment of principal of loans and the payment of interest. Progress has been so rapid that the estimated output of 1,520,000 units, given when the station was extended, and which it was thought would take years to reach, has already been exceeded by 700,000 units.

HALIFAX: *Insurance Scheme.*—The Halifax Tramways Committee on January 3rd unanimously adopted a suggested scheme for the formation by municipalities and tramway companies of a fund for mutual insurance against tramway accidents. It was resolved to ask the Town Council to take the initial steps for convening a conference of representatives of corporations and tramway companies at which the matter might be considered. The proposed scheme is to cover the total liabilities incurred from any accident during a whole year. At present the Halifax Corporation have their liability covered only to the extent of £1,000 on a single accident, and up to a total of £4,500 for one year.

HULL: *Explosions in Electric Cable Manholes.*—Considerable damage has been done to several of the manhole covers due to an accumulation of gas in the cable ducts, which became ignited. A considerable portion of the pavement was blown up in one case. Eight manhole covers in all were blown off in the district. The windows of the surrounding property suffered severely, and Trinity House and the Inland Revenue offices had scarcely an unbroken pane of glass left in the front of the buildings.

LONDON: *Battersea: Electricity Undertaking Progress.*—The number of consumers on the books of the electricity undertaking on December 17th was 1,065, against 1,015 at the end of the previous quarter. Energy was supplied for private lighting on December 17th equivalent to 73,170 8-c.p. lamps, an increase during the quarter of 4,578 lamps, and motive power was being supplied equivalent in h.p. to 1,706, an increase during the three months of 316. The public lamps only increased during the quarter by eight 8-c.p.'s to 6,272. The Finance Committee has approved of a contribution out of the Borough funds of one-third of the cost of the improvements in connection with the electrification of the tramways on Lavender Hill and St. John's Hill.

Hackney: Electricity Sales Department.—The Electric Lighting Committee of the Hackney Borough Council has decided to found an advisory and sales department in connection with their undertaking, and to appoint a sales engineer at a salary of £120 a year, increasing by £10 a year to a maximum of £150; the permanency of the appointment will depend on the success of the department. In order to encourage the accession of consumers, it is desirable that a showroom should be equipped for the exhibition of various kinds of fittings, lamps, radiators, motors, and other apparatus, can be shown in operation, and where clients could get all the information they required. It is proposed to commence the initial scheme from the existing offices. It will be the sales engineer's duty to take charge of the Council's sales department, and canvass for orders under the direction of the borough electrical engineer. The committee have drawn up a scheme for providing consumers with electrical installations:—(1) (*a*) A cash purchase system; (*b*) a hire purchase system, including inspection, insurance, and maintenance of wiring, switches, and fuses during the hiring period, with payments by instalments spread over a term agreed upon with the consumer (not in any case to exceed five years), after which the installation is completely the property of the consumer. The charge to the consumer to be made up of (i.) the capital outlay on the installation, *i.e.*, the net cost to the Council; (ii.) percentage additions thereto for administration, supervision, inspection, maintenance, insurance, and profit; (iii.) interest on outstanding instalments. (2) The installation work to be carried out by approved contractors. (3) Arrangements to be made for the maintenance of consumers' apparatus by the Council as occasion requires. The committee will submit a report as to the financial arrangements which may be necessary and a scale of charges for the services of the department.

The Electrification of the Tramways.—An intimation was received from Hackney Borough Council that they have decided to withdraw their objection to the adoption by the L.C.C. of the overhead system of electric traction in Lea Bridge Road. Mr. Heather (Chairman of the Committee) said he hoped the L.C.C. would now proceed with the scheme.

Hammersmith: New Sub-Station.—The Electricity Committee of the Borough Council has decided to erect a standard sub-station at the corner of King Street and Down Place, with permanent switchgear at a cost of £365.

The Law and Parliamentary Committee has decided in favour of opposing the Bill to be presented in the forthcoming session of Parliament to incorporate the West London, Barnes & Richmond Tramways Co., and to empower the company to make and maintain tramways and other works in the counties of London and Surrey, to confer further powers in respect of the Richmond (Surrey) electric light undertaking, and for other purposes.

Franco-British Exhibition Electric Supply.—A draft agreement has been arrived at between the directors of the Franco-British Exhibition and the Law and Parliamentary Committee of the Borough Council to the effect that if there is a total failure

Digitized by Google

of the supply for 24 hours consecutively, the consumers will be entitled to a proportionate reduction in their liability for the guaranteed minimum payment.

Islington: North London Trams.—The Town Clerk of Islington has received a letter from the London County Council intimating that they propose to proceed at an early date with the reconstruction for electric traction on the conduit system of the tramways from King's Cross, via Caledonian Road, and Camden Road to Holloway Road, and thence, via Seven Sisters Road, to Finsbury Park.

Paddington: Electric Tramways Control.—The Works Committee of the Council, after an interview with the Improvements Committee of the London County Council, recommend that, subject to the Metropolitan Electric Tramways (Limited) agreeing with the Paddington Council with regard to widening Harrow Road, no opposition be offered the company's Bill for extending their lines within the borough. Further, the Works Committee recommend that such representations be made to the Board of Trade as may appear necessary concerning "the inconvenience which would result in the event of there being dual control of the tramway lines in Paddington."

The company called attention to the inconvenience which would be caused to residents in Paddington if the service of cars between Willesden and Lock Bridge had to be stopped at the county boundary. Representatives of the Borough Council waited upon the Improvements Committee of the L.C.C., and informed them that if the tramways were extended through Paddington the local authority would not bear any portion of the expense of street widenings. They would also expect recoupment of the expense incurred in carrying out the improvement at Pickford's. The chairman of the Improvements Committee of the L.C.C. stated that the County Council were not proposing to put forward a Bill this year, but they would consider the clauses of the Tramways Company's Bill, and try to bring about an agreement between the parties concerned.

Woolwich: Rates for Lighting and Power.—At the meeting of the Borough Council on January 2nd the Council came to the following decision:—(*a*) That when the load factor of any consumer taking a supply of energy for power purposes upon which the actual maximum demand exceeds 15 per cent., or the supply is for heating purposes, no time switches shall be installed, and the supply shall be given at a flat rate of 1d. per unit net, provided that such consumer undertakes to restrict the demand for power purposes on peak load to a minimum. (*b*) That when the load factor of any consumer taking a supply of electrical energy for power purposes exceeds 15 per cent., calculated as above, such consumer shall have the option to use not more than 7 per cent. of the total energy demanded for lighting purposes. The acting engineer also made a report with reference to the price of supply to illuminated signs, shop facias, &c. The Electricity Committee, when the question of price was before them some months ago, were reluctant to grant power rates for this purpose, on the ground that it was a matter of lighting, not power, and fixed the price at 2d. per unit. The engineer desired to have authority to quote power rates when any demand was made by a consumer whose load factor exceeds 15 per cent., equivalent to 1,312 hours of steady use per annum. The Council decided to continue the rate of 2d. per unit for current for electric signs and illuminated facias in cases where the load factor was less than 15 per cent., and at the rate of 1d. per unit net when the load factor exceeded 15 per cent. The Council's costs in opposing the London County Council (Electric Supply) Bill, the Administrative County of London and District Electric Power Bill, and the London Electric Supply Bill, last Session, amounted to £284 13s. 9d., and this sum will be made a general charge upon the borough funds.

LONGTON: *Electric Tramways.*—A report has been received by the Town Council with regard to the inspection of the tramway lines by Colonel Druitt, and it was intimated that the Board of Trade had consented to the continuance of the use of electricity on the lines generally.

OXFORD: *Dolter Surface Contact System.*—In connection with our reference to this matter last week, we are now able to give the report of Mr. Stephen Sellon to the Oxford Corporation upon the visit of a delegation from the Corporation to Hastings, and the working of the Dolter system there. The report, which is addressed to the Town Clerk, reads as follows:—"In accordance with your instructions, I accompanied the members of your Corporation to Hastings on December 16th, for the purpose of inspecting the tramway system installed there by the Dolter Company. By section 62 (2) of the Oxford and District Tramways Act, 1907, it is provided that the City of Oxford Electric Tramways, Ltd., may instal the Dolter surface-contact system in Oxford if it can be proved that such system has been working satisfactorily for six months in any place in Great Britain, and I understand that the visit to Hastings was made with the object of deciding whether your Corporation would be justified in permitting the adoption of this system at Oxford. As requested, I now give my views in writing:—Your Corporation will bear in mind that on September 25th, 1906, I reported upon various surface-contact systems which had been inspected by them, and in dealing with the Dolter system I expressed the opinion that the experimental stage had not yet been passed. I am still of that opinion. No system can be said to be in any other than an experimental stage if, in addition to the ordinary working expenses and staff required on a tramway system, the services of a patrol, numbering about four men to the mile, is necessary for the purpose of locating and dealing with live studs; neither is the possibility of live studs permissible in the streets of Oxford. The natural advantages which were secured by the Dolter Company at Hastings for a working example of their system are obvious—a level line, wood pavement, comparatively light vehicular traffic, further assisted by being laid on the side of the road. These exceptionally favourable circumstances are not present in Oxford, and therefore any failures in Hastings will be accentuated in Oxford. A perfected system is one that is not only satisfactory in respect to mechanical efficiency, but also in respect to economical working. A system which requires upon a level road 25 per cent. more current than the average electrical undertaking, besides the addition in staff above referred to, cannot be deemed satisfactory. Section 6 (2) of the above-mentioned Act also provides that should the Oxford and District Tramways fail to meet their obligations in the way of rent, the Corporation shall be entitled to take possession of the tramways on the terms of purchase provided by section 43 of the Tramways Act, 1870, which, in other words, represents the then structural value of the undertaking, less depreciation, irrespective of whether the line pays or not. Under those circumstances, therefore, it is to the Corporation's interest that the line should be capable of being worked at a profit, and it is essential that the system selected should ensure this. There have been no reliable figures of working expenses presented up to the present by the Dolter Company, so I am of opinion that your Corporation should hesitate before coming to a decision, especially having regard to the fact that the tramway company cannot possibly commence any construction for at least six months. Another reason I suggest for delay is that the Hastings Tramway Company are under an agreement with the Dolter Company whereby the former are bound to take over the system on January 12th next, should the system comply with the terms of the Dolter Company's guarantee. It would appear wise, therefore, if your Corporation would await the decision of the Hastings Tramway Company, who have been carefully watching the working of the system for the last twelve months, and have collected information (impossible to obtain by a casual inspection) as to whether or not they consider the Dolter Company have carried out their obligations. It cannot be expected, nor do I consider it would be reasonable to suggest, that your Corporation should be called upon to give a decision on an important matter of this sort without first receiving the best technical advice; neither would it be reasonable for them to be asked to bear the burden of a decision which might result in Oxford possessing permanently an unsatisfactory system of tramways. I therefore strongly advise that advantage be taken of the protective clause afforded by the Act of 1907, and to say that on the advice of their consulting engineer the Corporation are of opinion the line at Hastings has not worked satisfactorily for the last six months. This is no injustice to the Oxford Tramways Company, as obviously they are as much interested in obtaining the best possible system as the Corporation. Upon the Corporation taking up this attitude the onus is then on the Dolter Company to show that the line has been working satisfactorily in Great Britain for the last six months, and they are entitled to ask for the appointment of an arbitrator to decide this question. If your technical adviser is wrong they have nothing to fear. I advise your Corporation to adopt this course, thus placing the responsibility of choice of system upon the arbitrator and thereby obtaining relief from a responsibility of a highly technical character, which I do not think they ought to be subject to criticism for hereafter."

SPALDING: *Urban Council Surcharge.*—The surcharge of £66 upon the members of the Urban Council (see ELECTRICAL ENGINEERING, January 2nd, 1908, p. 28), has now been withdrawn.

SUNDERLAND: *Electricity Station Extensions.*—On Monday afternoon last, the new turbo-generator and boilers and stoking equipment were put into use for the first time. The turbo-generator has cost £10,551, and is of 2,000 kilowatts capacity, and works at 1,500 revs. per min. The boiler and plant have cost £15,708, and the total extensions, including switchboards, &c., have cost £41,600.

SWANSEA: *Demand for Electricity.*—At the ordinary meeting of the Swansea Electricity Committee on Thursday the engineer reported an increase in the consumption of electricity, and the Chairman (Colonel Sinclair) said if the same rate of progress was made next quarter the annual results should be most satisfactory, notwithstanding that the newer pattern lamps reduced the consumption by one-third. The London & North-Western Railway Co. asked for terms for electrically lighting its sidings. It was said the mains would cost from £425 to £570, while the number of lamps required would only be eight, but as these would be burning all night they would give an excellent total. The engineer said he hoped soon to obtain an order for electrically lighting the Midland Station. The committee decided to have further information.

Digitized by Google

TUNBRIDGE WELLS: *Municipal Electric Lighting.*—The Tunbridge Wells Town Council, at its meeting yesterday, took the control of public lighting from the Electric Lighting Committee and placed it with the Watch Committee. It was contended that the former committee, being in the position of buyers and sellers, had carried on an extravagant system of public lighting, which had increased the cost to the ratepayers by £2,000 per annum, as compared with twelve years ago, when gas was exclusively used. It was declared that the Electric Lighting Committee had bolstered up the "profits" of the municipal undertaking by this policy.

YORK: *Corporation Electricity Show-rooms.*—The Electricity Committee have decided to open premises in the city for the exhibition of electric light fittings, &c. This course has been adopted in spite of a protest from the electric contracting firms of the city.

TENDERS INVITED AND PROSPECTIVE BUSINESS

AUSTRALIA.—In reference to the notice on page 953 of our issue for December 12th, Mr. J. Cresswell, the Board of Trade correspondent at Adelaide, has forwarded a copy of the specification and conditions relating to the supply and delivery to the Municipal Tramways Trust, Adelaide, of special work, points and crossings for tramways. Sealed tenders, endorsed "Tender for Special Work," must reach the Chairman, Municipal Tramways Trust, 8 King William Street, Adelaide, by noon on February 11th, 1908. Tenders must be accompanied by a preliminary deposit equal to one per cent. of the total amount of the tender. The specification and conditions may be examined by British manufacturers at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, E.C.

The Victorian Postmaster-General's department invites tenders by May 26th, 1908, for the supply of one common battery switchboard of thirty sections, complete with frames, racks, power plant, and parts; also for 3,000 telephone wall sets; 1,000 telephone table sets; 150 extension switches, complete; 10 switchboards, for 2 and 6 lines; 50 switchboards, for 3 and 10 lines; 10 switchboards, for 6 and 20 lines; 10 switchboards, for 8 and 50 lines; 200 telephone wall sets, for party lines; and 100 telephone wall sets, for party lines. A copy of the specification may be seen at the Commercial Intelligence Department of the Board of Trade, 73 Basinghall Street, London, E.C.

News received by the Australian mail, which arrived in London on Monday, states that the Postmaster-General has been authorised by the Commonwealth Cabinet to call for tenders at once for the installation of wireless telegraphy on several places round the coast of Australia. The places to be linked up are King's Island and Tasmania, Rottnest and some convenient centre on the North-West coast, and Port Moresby and Yorke's Peninsula. The tenderers will be required to sell the Australian rights of their system right out to the Commonwealth Government.

BANGOR.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £1,000 for the purposes of the electrical undertaking.

BARNES.—The Council invite tenders for the delivery and erection at the Council's depôt, High Street, Mortlake, London, S.W., of a two-ton electric locomotive crane. Full particulars from the Engineer's and Surveyor's office, High Street, Mortlake, to whom tenders should be sent by January 13th.

BEDFORD.—Some extensions to the mains are to be carried out.

BUENOS AYRES.—The *Review of the River Plate* states that the Buenos Ayres Municipality are calling for tenders for a period of six months—May 1st, 1908—for the construction of two tube railways, and also for the renting and working of same when built. Full particulars can be obtained in the Argentine Legation in the following cities:—London, Paris, Berlin, Brussels, Rome, and New York.

BURY.—On Friday the Town Council adopted a resolution of the General Purposes Committee that a scheme be carried out for the laying down of electricity generating plant at Chamber Hall for giving a supply on the alternating current system. The immediate estimated capital expenditure will be £70,000, with a possible subsequent expenditure of £15,000.

EDINBURGH SCHOOL BOARD.—The Board are prepared to receive estimates for an electric light installation at Portobello Higher Grade School. Specifications may be obtained at the office of Mr. George Thompson, 11 Randolph Place, and tenders to the Clerk, School Board Offices, Castle Terrace, Edinburgh, by January 11th.

FINCHLEY.—Tenders are invited for the supply and erection of a 350 kw. high speed engine and dynamo combined, together with spare parts. Particulars from the Electrical Engineer (Mr. E. Calvert), Electricity Works, Squire's Lane, Finchley, N. (fee £2 2s., returnable), and tenders to the Town Clerk by January 20th.

GLASGOW.—The Corporation invite tenders for the supply of a 4,000 kw. turbo-alternator running at 750 r.p.m. Copies of the specification and form of tender may be obtained on application to Mr. W. W. Lackie, engineer, 75, Waterloo Street, Glasgow (fee two guineas, returnable), and tenders to the Town Clerk by January 14th. (See advertisement last week.)

ILFORD.—Tenders are required for the supply of feeder cable. Specifications, conditions, &c., from Mr. A. H. Shaw, Electrical Engineer to the Council, and tenders to the Town Clerk by January 14th.

INDIA.—Tenders are invited by the Bengal and North-Western Railway Co. for 15,000 incandescent lamps. Specifications may be obtained at the company's London offices, price 10s. (not returnable), and tenders should be addressed to the Managing Director, 257 Gresham House, Old Broad Street, E.C.

KILKENNY.—The Joint Committee of Management of the Kilkenny and District Lunatic Asylum invite tenders for (1) suction gas plant, gas engines, and generators; (2) accumulators, switchboard, mains, &c. Plans may be inspected by appointment at the Asylum or at the office of the consulting engineer, Mr. L. J. Lawless, 27 Castlewood Avenue, Rathmines, Dublin, from whom copies of the general conditions, &c. may be obtained (fee, three guineas, returnable). Tenders to the Resident Medical Superintendent by January 18th.

LEYTON.—The Urban District Council, at their last meeting, decided to fix three arc lamps in Church Lane, Leytonstone. The annual cost will be £21 each. These will replace five electric incandescent lamps costing £4 3s. 6d. each. The additional premises recently acquired in connection with the electricity undertaking are to be fitted up at a cost, including telephones, of £138 and £126. In reference to the decision of the Council some time ago to convert the arc lamps in High Road, Leyton, into flame arc lamps, the Engineer was empowered to acept offers of flame arc lamp manufacturers to erect three lamps on trial. The lamps must be capable of burning 37 hours with one trimming, to take nine amperes, and, if possible, to burn four in series on 150 volts.

LIMERICK.—The Board of Guardians is considering the advisability of erecting a sanatorium for consumptives, which will be electrically lighted.

LONDON: *London County Council.*—Tenders are invited for the supply and delivery of about 500 tons of steel slot rails and about 190 tons of conductor rails, required for the reconstruction on the underground conduit system of electric traction of certain sections of the Council's tramways. The rails must be of British manufacture. Full particulars, forms of tenders, &c., from the Chief Engineer to the Council, Mr. Maurice Fitzmaurice (fee £2, returnable), and tenders to the Clerk to the Council by January 21st.

Camberwell.—Tenders are invited by the Borough Council for electric lamps, among other stores; also the maintenance of private telephones and electric bells. Particulars, forms of tender, &c., from Mr. William Oxtoby, Borough Engineer, Town Hall, Camberwell, S.E., by specifying sections desired. Tenders to the Town Clerk by January 20th.

MANCHESTER.—The Corporation Tramways Department invite tenders for the following machine tools: car wheel turning lathe, self-acting and screw-cutting lathe, and high-speed vertical drilling machine. Particulars from the General Manager, 55 Piccadilly, to whom tenders by January 14th.

MARSEILLES EXHIBITION.—A Paris firm, contractors for luminous decorations and art lighting, who are concerned in work of this character to be done at the Electrical Exhibition at Marseilles next year, are desirous of obtaining novelties of all kinds in connection with their industry in the way of lamps, lamp stands, conductors, reflectors, decorative shades, &c. They will be glad to receive samples, catalogues, or descriptive notices from British makers, and to be informed what quantities of the goods named makers would be prepared to place gratuitously at their disposal during the exhibition in exchange for the advertisement which the makers would have from the display of their wares. For further particulars manufacturers should apply to the Secretary of the British Chamber of Commerce, 17 Boulevard de la Madeleine, Paris.

PLYMOUTH.—The Plymouth Corporation is prepared to receive tenders for the supply of the undermentioned stores during the twelve months ending March 31st, 1909:—Arc lamp carbons, electricity meters, transformers, cables (paper insulated), lubricating oils, &c., engine waste, &c. Full particulars from Mr. E. G. Okell, Borough Electrical Engineer (fee, ten shillings for each specification, returnable), to whom tenders by January 23rd.

ROTHERHAM.—The Corporation invite tenders for the supply of tramway rails, fish-plates, tie-bars, bolts and nuts, and special trackwork, to be delivered in Rotherham. Speci-

Digitized by Google

fications, &c. (fee one guinea, returnable), from the Borough Engineer, and tenders to the Town Clerk by January 17th.

SOUTH AFRICA: *Kroonstad.*—Tenders will shortly be invited for generating plant by the municipality.

VIENNA.—Preparations are being made for the issue of a loan of from £10,000,000 to £12,000,000 for the extension of the tramways and electric lighting system, in addition to a large number of other public works.

TENDERS RECEIVED AND ACCEPTED

CARDIFF.—Messrs. Bruce Peebles & Co., Ltd., have received from the Cardiff Corporation an order for a 250 kw. Peebles La Cour motor converter, this being a duplicate of the unit previously ordered.

DARWEN.—The Electrical Engineer having tested coal required for the local electricity works, the Town Council on Monday decided to accept the tender of the Clifton & Kearsley Coal Co. for a period of six months for the supply of coal to these works.

LEYTON.—The Urban District Council has received the following tenders for the supply of cables for extensions to mains:—Lahmeyer Electrical Co., Ltd. (accepted), £1,785 10s.; Western Electric Co., £1,872 10s. 3d.; British Insulated and Helsby Cables, Ltd., Lancs, £1,904 13s. 4d.; Johnson and Phillips, £1,909 10s.; Siemens Bros. & Co., Ltd., £1,910 11s. 6d.; W. T. Henley's Telegraph Works Co., £1,924; St. Helens Cable & Rubber Co., £1,947; Callender's Cable & Construction Co., Ltd., £1,955 10s.

The tender of Mountain & Gibson, Ltd., has been accepted for the supply of car wheels at £3 17s. 6d. each, wheel tyres at £1 17s. 6d., and wheel centres at £2 each, a reduction of 1s. per tyre being made for 2-in. tyres.

The following tenders have also been received for the supply of 100 public lighting lanterns:—W. Edgar, £2 9s. 5d. per lamp, or £246 5s. per hundred; Electrical Co., Ltd., £525 per hundred; W. Lucy & Co., Ltd., £240 16s. per hundred; General Electric Co., Ltd., £250 per hundred; Crown Lamp Works, £360 per hundred. The tenders were referred to the Electric Lighting Committee for consideration.

LONDON: *Stepney.*—Messrs. Bruce Peebles & Co., Ltd., have secured, through Messrs. Willans and Robinson, the Stepney Borough Council's order for a 200 kw. 6,000-volt 50-cycle three-phase turbo-alternator, to be driven at 500 r.p.m. by Messrs. Willans & Robinson's steam turbine.

Woolwich.—The Borough Council has decided to purchase a spare set of links for the chain grates of the boilers at Plumstead works from Messrs. Babcock & Wilcox for £27. The quotation of the Oliver Arc Lamp Co., Ltd., for the annual supply of 35,000 pairs of "Oriflame" arc lamp carbons for continuous current supply at £96 5s., and 10,000 pairs for alternating current supply, at £28 10s., has been accepted.

METROPOLITAN ASYLUMS BOARD.—An agreement has been entered into with the Electrical Power Storage Co., Ltd., to maintain the storage battery at Brook Hospital, Woolwich, for seven years from September 29th, 1907, at an annual sum of £70.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net c.i.f. port of arrival, quoted on Tuesday night, was £64 10s. to £65 10s. per ton (last week, £63 10s. to £64 10s. per ton).

LIQUIDATIONS, BANKRUPTCIES, &c.—The Electric Power Development Co., Ltd., is to be wound up voluntarily. Claims to Mr. G. R. Bostock, 21 Ironmonger Lane, London, E.C., by February 29th.

A meeting of the Phodene Electrical Co., Ltd., will be held at 66 Victoria Street, London, S.W., on February 4th, at 12 noon, for the purpose of hearing the liquidator's account of the winding up.

A meeting of Electrical Improvements, Ltd., will be held at 44 Parliament Street, Nottingham, on February 17th, at 11 a.m., to hear the liquidator's account of the winding-up.

The discharge of Thomas Edward Morgan, electrical engineer, 367 Eccleshall Road, Sheffield, has been suspended for two years, as from December 5th, 1909.

THE WILKINSON FEED WATER HEATER.—From the commencement of this year the London and district agency for the above apparatus has been transferred from Messrs. Hall & Co. to Messrs. J. L. Cateaux & Co., of 10 Bush Lane, Cannon Street, E.C. Although these heaters are of recent design, we understand that a large and rapidly increasing business is now being done, both at home and abroad. Amongst the recent orders received may be mentioned the following:—Messrs. Pilkington Bros., St. Helens; The Hucknall Torkard Collieries Co., nr. Nottingham; The Calico Printers' Association; The Associated Portland Cement Co.; Messrs. Pease & Partners, Stockton; Messrs. Clarke, Chapman & Co., Messrs. Goodwin & Co. (the two latter being repeat orders); the electricity works of Blackpool, Blackburn, Londonderry, Bedford, Ashton-under-Lyne, and repeat orders from Luton and Wakefield electricity works.

COMPANIES' MEETINGS AND REPORTS

BURMAH ELECTRIC TRAMWAYS AND LIGHTING.—The report for the year ended July 31st last states that the receipts have barely covered the expenditure, in spite of the fact that the outgoings for current expenses have not appreciably increased. The great exodus of population due to the continuance of the plague is stated to be responsible for a decrease in the receipts of about £1,000. Nevertheless, the directors think that this is less than might reasonably have been expected, and that it indicates the usefulness of the undertaking, which may be expected to develop with a return to normal conditions. This view is upheld by the fact that since August last, when the plague was reported to have ceased, an improvement in the receipts has been manifested. The difficulty of the coal problem still continues. No coal has yet made its appearance in Mandalay, and the company has still to rely upon wood for their heating power, and for this reason it has been impossible to effect any reduction in the charges for power, which continue abnormally high. In other directions some economies have been made. Notwithstanding the unlooked for check due to the plague from February, 1906, until August, 1907, a very large number of riders, about 50,000 per week, continued to use the tramways, so that the report states it is evident that the want of expansion was not due to any hostility to the tramways, but to circumstances entirely apart.

At the meeting on Tuesday last week, the report and accounts were adopted.

LONDON SOUTHERN TRAMWAYS.—At an extraordinary general meeting on Friday, the secretary was authorised to distribute the balance of the funds available to the shareholders in connection with the sale of the undertaking to the London County Council. Mr. W. M. Murphy presided. The accounts showed that, after paying the debenture holders and the creditors, there was a balance remaining of £10,162 for division among the shareholders, or £1 2s. 7d. per share. We gave a full statement of the position of the company's affairs in our issue for December 19th.

SOUTH LONDON ELECTRIC SUPPLY CORPORATION.—At an extraordinary general meeting on Tuesday, the following resolutions, already passed by the shareholders, were confirmed:—"(1) That by virtue of the powers contained in the Companies Acts 1867 and 1877 and the company's regulations, the conditions contained in the memorandum of association be modified by the reduction of the existing nominal capital of the company from the sum of £325,000 to the sum of £260,000, thus reducing the capital of the company by £65,000, and that such reduction be carried into effect by the alteration of the 65,000 shares of £5 each now forming the capital of the company into 65,000 shares of £4 each. (2) That in accordance with the above resolution the capital of the company shall henceforth stand as follows, namely, the nominal capital of the company shall be £260,000, divided into 65,000 shares of £4 each." During the course of a short discussion it was stated that the refuse destructor has been dismantled.

POCKET-BOOKS, CALENDARS, Etc.

Copies of a pocket diary for 1908, with a full page for each day, in addition to space for memoranda, are being distributed by Messrs. Mountain and Gibson, Ltd., of Bury. A number of interesting illustrations of different types of tramway and railway trucks of the firm's manufacture are included, together with views of complete cars to which these are fitted.

The Consolidated Accessories Co. send out a card with the season's greetings, giving figures showing the increasing sales of their "Peacock" tramway brake outfits. The design of the card includes three black and white drawings, showing the action of the brake gear and with a spirited representative of the bird from which the apparatus takes its name, perched upon the brake handle. This is repeated three times in varying sizes, and is decoratively most effective.

The Western Electric Co. have issued a wall calendar embellished with illustrations of various forms of telephone apparatus, sections of cables, and other articles of their manufacture.

Telegraph Traffic.—The past week has been rather full of incidents in the telegraphic world, there being several interruptions to record. The Ceuta-Tangier cable was put into working order again on the 3rd inst., it having ceased working on December 6th last. Trouble has occurred between Rome and Constantinople; this land-line route gave out on the 1st inst. The "Via Fao" route was interrupted on the 3rd inst., and there is also an interruption between Bagdad and Bassorah. The cables between Scotland and the Orkney Islands, and Scotland and the Shetland Islands, ceased working on the 2nd inst., and, as these cables form part of the means of communication with Iceland, it now becomes necessary to post messages for the Orkney, Shetland, Faroe Islands, and Iceland, from Scotland to the Orkney Islands, and messages are consequently subject to delay.

APPOINTMENTS AND PERSONAL NOTES

Mr. Keats, Acting Electrical Engineer to the Woolwich Borough Council, has been appointed Electrical Engineer at a commencing salary of £325 per annum, rising by annual increments of £25 to £400.

The Darwen Electricity Committee decided on Monday to give the electrical engineer, Mr. C. Fawcett, an increase of salary from £250 to £275 from New Year's Day, 1908, and a further increase to £300 per year from January 1st, 1910.

Mr. Harry Heys, assistant clerk at the Burnley Electricity Works, has been appointed chief clerk at the Mansfield Electricity Works.

The Nelson Electricity Committee has decided that the salary of Mr. Nayler, Assistant Electrical Engineer, be increased from 45s. to 50s. per week.

Mr. J. D. Caird, of Aberdeen, was on Friday appointed Traffic Superintendent of the Halifax Co.'s Tramways at a salary of £250, rising to £350 per annum.

The Electricity Committee of the Manchester Corporation have recommended that Mr. S. L. Pearce, Chief Electrical Engineer, be reappointed for four years, the salary for the first two years to be £1,100 per annum, and for the last two years £1,200 per annum, Mr. Pearce to devote the whole of his time to the duties of the position.

On his transfer to the Newcastle district, Mr. Callaghan, Assistant Engineer in the Darlington postal district, has been presented with a gold ring and a silver mounted pipe by the Darlington telegraph staff.

No less than 200 applications were made for the post of City Electrical Engineer at Carlisle, the salary being £300 a year, with annual increases of £20 to a maximum of £400. The following have been selected to appear before the committee:—Mr. T. S. Allen, Plymouth; Mr. W. W. Alston, West Bromwich; Mr. O. F. Francis, Kirkcaldy; Mr. C. F. McTomes, Gravesend; Mr. B. S. Hornby, Bolton; and Mr. C. L. E. Stewart, Rochdale. At the meeting on Tuesday, Mr. Francis was unanimously elected to the appointment.

We learn that Mr. F. J. Moffett and Mr. N. B. Rosher, who have until recently been engineers on the staff of Messrs. Preece & Cardew, have commenced to practice as consulting and inspecting engineers at Union Chambers, Temple Row, Birmingham. They intend to devote special attention to the electrical equipment of works and factories, and also to the inspection and testing of all kinds of engineering plant and material, several of the leading London consultants having already appointed them as their inspecting engineers in the Midlands and Lancashire. Mr. Rosher held the post of resident engineer for the building and equipment of Messrs. Siemens' Dynamo Works, Stafford, and, under Messrs. Preece & Cardew, for the electrical equipment of H.M. Dockyards at Chatham and Simon's Bay, S. Africa. Mr. Moffett has had a long and varied experience of Colonial work.

NEW COMPANIES

BRITISH ELECTRICS (MOSELEY'S PATENTS).—This company was registered on December 31st, 1907, with a capital of £10,000 in £1 shares, to acquire and turn to account inventions relating to the manufacture of electric, magnetic, telegraphic, telephonic, and other appliances, and certain patent rights and other property referred to in an agreement dated November 19th, 1907, between W. Moseley and F. de H. Larpent, and with a view thereto to adopt an agreement with the said F. de H. Larpent. The subscribers are:—J. J. Ireland, A. G. Hastings, A. Klein, C. D. Moggridge, R. H. Peren, H. E. Luker, J. H. East. No initial public issue. The number of directors is not to be less than three nor more than five: the first is W. Moseley and others to be appointed by the subscribers. Remuneration, £100 each per annum (chairman, £150), and 10 per cent. of the profits remaining in any year after 10 per cent. dividend has been paid.

CHECKOGRAM (1908).—This company was registered on January 3rd, with a capital of £51,000 in £1 shares, to acquire the undertaking of Checkogram, Ltd. (incorporated in 1904), to adopt an agreement with the said company and its liquidator, and to carry on the business of manufacturers of and dealers in mechanical and electrical appliances for delivering, receiving, counting, checking, or other operations and mechanical and electrical indicators, turnstiles, gates, tickets, checks, perforating and stamping presses, lamps, alarms, contact makers, boxes, frames, cases, fibre, vulcanised fibre, vulcanite and the like, electricians, suppliers of electric or other power, engineers, &c. The subscribers are:—W. B. Purefoy, W. Leon, Col. C. W. Cox, Capt. H. F. Darell, W. Slark, J. M. Cobban, P. H. Edwards. No initial public issue. The number of directors is not to be less than three, nor more than seven; the first are W. B. Purefoy, W. M. Leon, C. W. Cox, and Capt. H. F. Darell. Qualification, £500 shares or stock. Remuneration, £400 per annum, and not more than £600 out of the surplus profits remaining in any year after providing for reserve fund and for 20 per cent. on the ordinary shares, dividend. Registered office, 150 Oxford Street, W.

I. HARRIS & SONS.—This company was registered on December 28th, with a capital of £1,000 in £1 shares, to acquire the business of a dealer in talking machines and electrical and optical goods carried on by B. Harris at 4 Blue Boar Court, Manchester, as I. Harris & Sons, and to carry on the same and the business of manufacturers of and dealers in lubricating and other oils, indiarubber, &c. No initial public issue. Table "A" applies. The first directors are B. Harris and A. Harris. Registered office: 4 Blue Boar Court, Manchester.

MISCELLANEOUS CITY NOTES

CHILI TELEPHONE CO.—The usual interim dividend for the half-year ended September 30th, at the rate of six per cent. per annum free of income tax, has been declared.

CITY OF LONDON ELECTRIC LIGHTING CO.—Warrants in payment of the interest on this company's £400,000 5 per cent. and £300,000 4½ per cent. second debenture stock for the half-year to December 31st, 1907, have been duly posted.

CITY OF WELLINGTON ELECTRIC LIGHT & POWER CO.—As a consequence of the purchase of the undertaking of this company by the municipality, subscriptions are being invited at par for four per cent. debentures to the amount of £147,500 through the Union Bank of Australia. The list closes on Saturday. Although issued on behalf of the company, the issue is secured upon the city rateable value.

NEW PUBLICATIONS

"Science Abstracts." December, 1907. Section A, Physics; Section B, Electrical Engineering. (London: E. & F. Spon, Ltd.) 1s. 6d. each.

"The Mechanical World" Pocket Diary and Year Book for 1908. (Manchester: Emmott & Co., Ltd.) 6d. net.

"The Mechanical World" Electrical Pocket Book for 1908. (Manchester: Emmott & Co., Ltd.) 6d.

Large Gas Engines in Germany.—We have received from Mr. Leonard Andrews, of The Key Engineering Co. a large framed copy of the group that was taken at the works of Messrs. Ehrhardt and Sehmer at Saarbrucken, on the occasion of the visit of a party of English engineers to the Continent in October last, to inspect some notable installations of large gas engines and electrical plant. An accompanying picture represents the largest of the gas engines inspected during the tour.

New York Traction Companies Receivership.—The receivers for the Metropolitan Street Railway Co. and New York City Railway Co., who were appointed in August, have applied to the United States Circuit Court for instruction regarding the operation of the Third Avenue Railway Co., one of the affiliated undertakings. In a report to Judge Lacombe, which is given in the *Street Railway Journal*, it is stated that the Third Avenue Railroad was leased in April, 1900, to the Metropolitan Company for a term of 999 years. The latter corporation was thereby obliged to pay a quarterly dividend upon the Third Avenue capital stock of 6 per cent. from 1906 to 1910. The quarterly dividend due October, 1907, amounting to $239,937, was, by order of Judge Lacombe, defaulted. The lease also stated that the Third Avenue had executed, or was about to execute to the Morton Trust Company, as trustee, a "first consolidated mortgage" to secure payment of bonds amounting to $35,000,000, and that the Metropolitan Company guaranteed the prompt payment of interest and principal. There is now outstanding $37,560,000 of the bonds referred to, with a semi-annual interest at the rate of 4 per cent. and that on January 1st the sum of $751,200 will be due. Having no money to pay such interest, the receivers ask the court for instructions. There is also outstanding a prior issue of bonds by the Third Avenue, amounting to $5,000,000, bearing 5 per cent. interest, which constitutes a prior lien upon the property to the first consolidated mortgage, the petition says. At present the operation of the Third Avenue Railroad costs about $1,300,000 more than its receipts from all sources. Further, the receivers think there is no reason to expect an increase in the gross earnings sufficient to offset the increase in operating expenses which may reasonably be anticipated owing to the tendency toward higher prices for material and labour. Figures are also given showing a decrease in the gross earnings between 1896 and 1907 from $2,628,628 to $2,098,705. This result is mainly attributed to fraudulent use of the system of transfers, which is regarded as inevitable in the present state of the law on this point. With the operation of the Third Avenue Railroad as a separate system, the receivers believe that the earnings would show a substantial gain. At present, however, the receivers are absolutely without means to pay rent and interest, the large proportion of which has not been paid since 1900, and amounts to $330,000 per annum. As the result of the working of the line since the date of the appointment of the receivers until November 30th, 1907, there is a cash balance of $257,188, but this would barely suffice to meet the indispensable requirements for December, especially in view of the fact that with the advance of the winter months the daily earnings show material diminution.

SUMMARY

The trial of the signalman, for manslaughter, in connection with the accident on the Metropolitan Railway at West Hampstead station last October, took place on Friday. The prisoner was acquitted. (Page 70.)

The cruiser *Kleber*, stationed at Casa Blanca, has succeeded in transmitting wireless telegraph messages to the Paris Eiffel Tower, a distance of 1,200 miles. (Page 71.)

Reviews of the following books appear in this issue:—"The Patents and Designs Act, 1907," by J. Roberts and H. Fletcher Moulton; "The *Mechanical World* Pocket Diary and Year-book," "The *Mechanical World* Electrical Pocket Book," Fowler's "Mechanical Engineers' Pocket Book," "The Science Year-Book." (Page 71.)

A correspondent makes some inquiries relating to the use of Osram lamps for street lighting. (Page 72.)

A Paper by Mr. J. F. C. Snell, read before the Institution of Electrical Engineers last week, reviewed the whole question of the cost of electric power supply. The first part of the Paper gave results of a large number of independent plants, and included many useful tables and data, some of which showed that in many cases it would be useless to attempt to supply from a central station at as low a price as the works could reach with their own generating plant. Most discussion was directed, however, to the latter part, in which a formidable array of figures were marshalled in support of the contention that a large number of electricity works were charging a lower price for electric power supply than that at which it could be generated and distributed, when due account was taken of the capital charges. He concluded with the recommendation that the expenditure on extensions to many smaller electricity works should be stopped, and that power should be supplied from large central stations owned either by power companies, county councils, or jointly by municipal authorities. In the course of the Paper, the author expressed himself strongly in favour of supply of alternating current to works, and emphasised the saving in having static transformer sub-stations instead of A.C.: D.C. sub-stations, and in this he was strongly supported by Mr. J. Rider, who opened the discussion, and expressed himself generally in accordance with the author's views on other points also. Mr. A. M. Taylor complained that no account was taken of the cost of distribution from the sub-stations, and that consequently the Paper was not applicable to the case of the small power user. Mr. A. H. Seabrook criticised several figures in the Paper, more particularly those relating to the capital cost of sub-stations and the cost of transforming the energy in them, both of which, he considered, were over-estimated. Mr. J. H. Jeckell also characterised as too

Digitized by Google

high the cost given for transformer sub-stations, and he did not think it correct to debit the power consumer with the capital costs of the lighting station. Mr. W. H. PATCHELL added some useful information with regard to the power consumption of private plants, and incidentally pointed out that much capital in mains would be saved when the use of metallic filament lamps would render it no longer necessary to regulate the pressure for lighting within the present close Board of Trade limits. The discussion was adjourned, and will be continued to-night in the meeting hall of the Institution of Mechanical Engineers. At the Dublin Local Section the Paper was also discussed. Mr. TOMLINSON gave the estimated costs in the case of a peat utilisation scheme he was engaged upon; Mr. RUDDLE, Mr. KETTLE, and Mr. SHEARDOWN criticised Mr. Snell's figures, and, together with Mr. Tomlinson, asked for further information as to the precise process by which he obtained them. (Page 73.)

A NEW petrol-electric omnibus has been put into service in London by Messrs. T. Tilling & Co., Ltd., and a trial trip was made from London to Dartford to the works of the makers, Messrs. J. & E. Hall & Co., last Thursday. The electrical equipment is on the Stevens' system. A 30-h.p. "Hallford" engine drives an interpolar dynamo, which supplies current to two motors, one of which drives each back wheel through worm gearing. A controller enables the motors to be connected in series or parallel. No series resistances are used, but the field of the generator can be varied. (Page 83.)

A DEMONSTRATION of the action of the Warner non-parallel axle tramcar truck was given on Friday last at the West Ham Corporation Tramway Depôt. (Page 88.)

AT the meeting of the Institution of Electrical Engineers on Thursday, it was announced that the Council had unanimously elected Col. R. E. B. CROMPTON (a Past President) as President for the remainder of the session. Col. Crompton took the chair after this announcement by Mr. C. P. SPARKS, the senior Vice-President, and in a short speech referred to the great loss which not only the institution, but the whole of the electrical industry, had sustained in the death of LORD KELVIN. He thanked the institution for electing him to fill the gap, and said he would do his best to make the session a success, although he was an old man and not so vigorous as he had been. (Page 89.)

AN electrically propelled fire escape of large size, with a telescopic ladder extending to about 90 ft., has recently been put into service at Liverpool. Two motors driving the front wheels are employed, and the battery is mounted directly over the fore carriage. Electrical power is used for erecting the ladder. (Page 89.)

MR. H. HENDERSON, in his Paper read before the Newcastle Local Section of the Institution of Electrical Engineers last Monday, described the equipment of the North-Eastern Railway Co.'s new goods warehouse at New Bridge Street, Newcastle, which utilises to the full the advantages obtainable, especially in the way of compactness of arrangement, by the use of electrically driven apparatus, and described some interesting forms of overhead revolving jib and other cranes, capstans, and wagon hoists. A number of speakers took part in the discussion, and a good deal of interest was shown, especially in the design of the capstan gear. (Page 91.)

MR. G. W. WORRALL read a paper on Tuesday last, at the Manchester Local Section of the Institution of Electrical Engineers, on magnetic oscillations in alternators, in which an account was given of the continuation of a series of experiments described in a previous Paper. A distinction was made between magnetic oscillations due to a pulsation in the magnitude of the flux and "to and fro" movements of the flux, and the conditions under which each in a maximum were investigated. Several oscillograms showing ripples in the P.D. wave, due to these causes, were shown. (Page 95.)

MR. S. W. BAYNES, the Electrical Engineer to the Borough of St. Pancras, has reported to his Council, advising opposition to the London Electric Power Bills, especially on the ground that the passing of either of the Bills would put the companies in a position to supply power in the St. Pancras area. (Page 98.)

ON Wednesday night of last week a Paper on "Electrical Measuring Instruments, and Some of their Weaknesses," was read before the Association of Engineers-in-Charge, by Mr. K. EDGCUMBE, in which the author pointed out that purchasers often did not state the most suitable range, when ordering instruments. He also then dealt with instruments with hold-back springs and a false zero, and remarked that in the testing of glow lamps, it was a waste of time to measure input correctly to 1 per cent. when determinations of candle-power cannot be relied on to about 5 per cent. The moving coil pattern of instrument was recommended for continuous currents, and the moving iron type for alternating currents. A list was given of the accuracies that could be legitimately demanded in the case of various types of switchboard instruments. (Page 99.)

UNDER "Electrical Science, British and American," appear notes on a platinum thermometer for measuring gas-engine temperatures, and on certain properties of selenium. In the Papers abstracted in the Continental section, KURZ discusses the effect of radioactive matter in the atmosphere upon measuring instruments; BLONDIN summarises the present state of the question of nitrogen fixation; and CHAUMAT describes a process for the electrical reduction of indigo. (Page 100.)

UNDER "Electrochemistry" reference is made to methods of electro-plating for obtaining firm and adherent deposits, also special methods in connection with nickel, brass, gold and silver. Experiments with the electrolysis of lead sulphide and a fused lead electrolyte are described, the current efficiency, however, hardly seems sufficiently high for the process to be a success. (Page 101.)

AMONG the specifications published by the Patent Office on Thursday last is one by the BRITISH THOMSON-HOUSTON CO. & DALTON, relating to improvements in the method of control of the electrodes of arc lamps of the converging carbon, or the parallel electrode type. Another specification by KANDO relates to the control of electric motors, or a number of motors, by a specially arranged resistance. C. G. NOBBS and C. G. NOBBS, Jun., have patented a radiator in which the water is boiled by the use of electric iron coil resistances, in the water chamber. Messrs. HOOKHAM & SPRAGUE have an improved method of regulating the train wheels for electricity meters, which ensures correctness of reading of the dials. A patent by POULSEN covers a system of receiving wireless signals. The ATELIERS-THOMSON-HOUSTON have improvements in the commutation of dynamo electric machines. Among the patents which expire during the current week are two of electrical interest, one by THWAITES & CAWLEY relates to a system of electric haulage for use on canals and other waterways, and which expires on January 18th; the other by G. H. WHITTINGHAM relates to an automatic device for removing resistance when starting motors, and replacing when the current is shut off the motor. (Page 102.)

THE Adelaide Electric Supply Co. are to supply the power for the working of the municipal tramways. The Bournemouth Corporation have appealed at the Quarter Sessions against the assessment of the poor

Digitized by Google

rate on their tramways system in Poole; the Recorder dismissed the appeal with costs. Brentford Council are not to oppose the Bill for running electric cars across the bridge. At Burton-on-Trent, the advantages of supplying power on the restricted hours principle has been shown in the electricity accounts, as many more units have been sold, although the peak load has practically remained stationary. The Camberwell Borough Council have sent a deputation to the Board of Trade complaining that the County of London Electric Supply Co. did not produce accounts showing the true position with regard to the Camberwell portion of the undertaking. Liverpool has constituted a record for the traffic receipts of its electric tramways. The Hackney Borough Council are inviting tenders for the loan of £34,265, of which £31,815 is required for electricity purposes. At Melbourne, by a fire at the post office stores, the department has lost £20,000 in copper wire and telephone apparatus. The Board of Trade have allowed overhead mains to be used in Merthyr for street lighting purposes. A town meeting of ratepayers of Morecambe have decided against purchasing the tramways in the town, and a poll will also be taken in Belfast with regard to the Bill for purchasing the Cavehill and Whitewell tramway system, to which there is much opposition. (Pages 103 to 105.)

TENDERS are invited by the Australian Postmaster-General's Department for a considerable quantity of telephone material, and also for wireless telegraph apparatus. The Cardiff Corporation requires a 500 kw. motor-generator, the Wimbledon Corporation a 1,000 kw. turbo-alternator, and the Yarmouth Corporation a 400 kw. continuous current traction generator. The East Ham tramways manager is to obtain quotations for top covers to five tramcars, and the London County Council invite tenders for the roadwork in connection with the reconstruction of the Caledonian Road and Seven Sisters Road horse tramways. New telegraph lines are to be constructed in Spain, and further extensions to electrical works are to be carried out in South Africa. Mr. O. F. Francis, of Kirkcaldy, who had been appointed electrical engineer to the Carlisle Corporation, has decided not to accept the appointment in view of an offer from the Kirkcaldy Corporation. The Carlisle appointment is to be offered to Mr. Allen, of Plymouth, who was second on the list of selected candidates. A circular has been issued to the shareholders of the British Westinghouse Electric and Manufacturing Co. dealing with the financial position. It is stated that the eleven months of 1907 to November show a trading profit of £76,000, and a net profit of £17,780, after meeting interest on loans and debenture interest. (Pages 105 to 108.)

IT is to-day almost a truism that the chief engineer and the successful consulting engineer must be able to view every problem, not only from the engineering, but also from the commercial aspect; yet there are constant examples of mistakes—sometimes of a serious nature—due to insufficient importance being attached to one or other of these two points of view. Mr. J. F. C. SNELL'S Paper, read at the Institution of Electrical Engineers last Thursday, is a veritable lesson in modern-day commercial electrical engineering. It deals with matters of a purely technical character, and attaches to each its due importance as an item in a revenue-earning undertaking. The folly of taking for granted that economies are necessarily effected in a manufacturing works by the substitution of power from the mains for independent generating plant, is made as apparent as the necessity for centralisation in general power supply, and the impossibility of approaching the most economical results with a multiplicity of small public generating stations. Mr. Snell's arguments are based on sound and logical reasoning, but, while agreeing with the majority of his conclusions, we feel bound to express the opinion that in one respect his deductions need correction. He gives a timely word of warning against the tendency of reducing to too low a point the prices charged by electricity works for power supply, but he forgets that if the prices charged by existing electricity works were consistently worked out on the basis he gives as correct, the growth of the power load would be so slow a process that the modification of existing generating stations to the most economical working conditions would, in some cases, be indefinitely deferred. If an electricity works manager had only to look forward to, say, a 10 per cent. increase in his output, there is no doubt that, in many of the cases in which Mr. Snell's "correct" charges for power are higher than the actual tariff, the result of the power load increasing more rapidly than the lighting load would mean a decrease in the percentage profit of the undertaking. But those who are responsible for the management of the undertaking must look further forward than this. As Mr. Snell himself points out, a works designed to furnish power on a large scale can supply at much lower prices than those which he characterises as too low. Where, therefore, there is a clear prospect of acquiring a load of such a nature as to enable this ideal to be attained, and to justify the equipment of the works being modified to supply the increased demand on the most economical basis, it would be wrong policy to keep prices up to a value that would be an effectual bar to the desired result. To this extent Mr. Snell's conclusions are at fault.

THE snowstorm last week was not heavy, but unfortunately the air at the time was at that particular temperature which causes the snow to cling to the wires, and to weight them to such an extent as to pull them down, and a large number of interrupted circuits was the result. The south of England was the chief sufferer; many telegraph and trunk telephone wires were interrupted, and the Kent district of the Metropolitan telephone area was also so badly affected that many of the subscribers' lines have not yet been restored. Another serious result was that several overhead fire-alarm wires in the metropolis were pulled down, and a number of false calls were received by the Fire Brigade, who turned out several times to no purpose. This last-mentioned inconvenience, however, is difficult to explain, for every modern and properly constructed fire-alarm system should be so arranged that the signal representing a fire call and that due to earthed wires are perfectly distinguishable. The case is one calling for investigation. As to the telegraph and trunk telephone lines, the delay in traffic that was caused will doubtless result in a resumption of the campaign for additional underground lines, in which the various Chambers of Commerce are usually particularly active. Now that the use of distributed inductance has been proved an effective means of neutralising the effect of capacity on long distance lines, and of rendering possible the use of a smaller conductor than would otherwise have been necessary, we trust that there will soon be a great extension of underground main telegraph and telephone lines. The extra first cost of these has, of course, still to be taken into account, as the large

Digitized by Google

majority of new lines can simply be added on existing poles. On the other hand, there should be a substantial saving in maintenance with underground lines, and they need not always be laid in quite such an expensive manner as the present underground trunk cables. The method now employed is so perfectly reliable that, of course, there must be some disinclination to modify it, but still it is quite probable that a less costly and equally efficient system could now be evolved, with the experience which the Post Office engineers must now possess.

THE story of the collision at West Hampstead station of the Metropolitan Railway last October, which was told by those concerned in the working of the trains at the inquest, at the Board of Trade inquiry, and again before a police magistrate, was once more repeated in the Central Criminal Court on Friday, when the signalman at West Hampstead was on his trial for manslaughter. Although the question of whether the unfortunate man actually tampered with the release box of the signalling instruments was never satisfactorily settled, it was admitted on both sides that the death of the three men in the train was due to the signalman's negligence, and that he had broken rules which, if kept, would have prevented the catastrophe; and even the prisoner's counsel virtually admitted that the man had told a lying story in the witness box. The "seventeen movements" which, it was said by his counsel, the prisoner had to perform "between each train," were given an exaggerated importance. It was not possible by performing one of these seventeen "movements" incorrectly to cause any more serious result than the stopping of a train, and such a mistake could not have caused the disaster. The fine point to be settled by the jury was whether the negligence could be described as "gross and culpable," and the result was that they gave the man the benefit of some doubt which appears to have arisen in their minds. They were doubtless considerably influenced in their decision by the judge, who almost directed them to return a verdict of not guilty; in doing so he was assuming a grave responsibility, for the fact that the signalman will not have to take the full consequences of his serious negligence cannot but have a bad moral effect on others in whose hands the safety of the travelling public may rest. The verdict comes as a strange contrast to a sentence passed by the same judge, in a case heard the previous day. He imposed a heavy sentence of imprisonment on a motor-car driver who had been unsuccessful in avoiding an old woman wandering about in the public road.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 16TH.

Royal Society.

4.30 p.m. Meeting at Burlington House, Piccadilly. Among the Papers down for reading are the following:—(1) "Alternate Current Measurement," by Dr. W. E. Sumpner, communicated by Prof. John Perry, F.R.S.; (2) "The Conversion of Diamond into Coke in High Vacuum by Cathode Rays," by Hon. C. A. Parsons, F.R.S., and A. A. Campbell Swinton; (3) "Preliminary Note on Certain Phenomena of the Electric Discharge through Rarefied Nitrogen," by Dr. G. J. Burch, F.R.S., J. E. Marsh, F.R.S., and R. de J. F. Struthers.

Union Electric Co.

7 p.m. Staff dinner at the Café Royal, Regent Street, London.

Rugby Engineering Society.

8 p.m. Ordinary meeting. Paper to be read:—"The British Locomotive," by A. W. S. Graeme.

Institution of Electrical Engineers.

8 p.m. Extra meeting at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, S.W. The discussion upon Mr. J. F. C. Snell's Paper, "Cost of Electrical Power for Industrial Purposes," will be continued.

FRIDAY, JANUARY 17TH.

Royal Institution.

9 p.m. Evening Discourse by Prof. T. E. Thorpe, F.R.S., on "The Centenary of Davy's Discovery of the Metals of the Alkalis."

SATURDAY, JANUARY 18TH.

Institution of Electrical Engineers: Students' Section.

10 a.m. Visit to the works of Messrs. Elliott Bros. & Co., Lewisham.

Royal Institution.

3 p.m. Afternoon Lecture I., on "The Electrification of Railways," by Prof. Gisbert Kapp.

THURSDAY, JANUARY 23RD.

Institution of Electrical Engineers: Leeds Local Section.

7.15 p.m. Meeting at the University, Leeds. Paper to be read:—"Notes on the Development of Turbo-Alternators, by Dr. Pohl.

Institution of Electrical Engineers.

8 p.m. Meeting at the Institution of Civil Engineers, 25 Great George Street, London, S.W. Paper to be read:—"Standard Performances of Electrical Machinery," by Rudolph Goldschmidt.

FRIDAY, JANUARY 24TH.

Physical Society.

5 p.m. Ordinary meeting.

SATURDAY, JANUARY 25TH.

Royal Institution.

3 p.m. Afternoon Lecture II., on "The Electrification of Railways," by Prof. Gisbert Kapp.

THE WEST HAMPSTEAD ACCIDENT

THE trial of William John Hollis, signalman on the Metropolitan Railway, for manslaughter of the three men who lost their lives owing to the collision between two electric trains at West Hampstead on the morning of October 26th last, came on at the Central Criminal Court on Friday before Mr. Justice Bigham.

Mr. R. D. Muir, for the Public Prosecutor, with whom was Mr. Arthur Gill, opened the case and submitted that there had been a wholesale neglect of rules on the part of the prisoner, and that if these rules had been obeyed the accident would not have happened. The prisoner had attempted to account for his negligence by declaring that a certain electrical instrument had failed to work, but there were inconsistencies in his attempts to substantiate the statement, and the prosecution alleged that there were three distinct untruths in his account of how the accident had taken place. Counsel then detailed the circumstances of the accident, which were fully reported in ELECTRICAL ENGINEERING, Vol. II., pages 672 and 685, pointing out particularly how Hollis, according to his own account, had thought he had heard the train in question pass in the fog, and had "offered" it to Boggis, the signalman at Kilburn, who had accepted it, whereas Boggis had sworn that it had never been offered to him. The incorrect method of entering the times of the trains in the book was also mentioned. Evidence was then called, and E. Boggis, signalman at Kilburn, deposed as to not having been offered the Willesden Green train of Hollis. J. Spittle, driver of the Willesden train, said that the starting signal had not been lowered until after the collision; and Benjamin Smith, driver of the oncoming train, gave his account of what had occurred. Edward Lyon, chief traffic inspector, and William Fitch, station foreman at West Hampstead, also gave evidence; and William Shepherd, the signalman who relieved Hollis after the accident, said that although the prisoner had told him that the disc instrument had broken down, it had worked quite well when he had tested it. Edward Phillips, engineer to the Metropolitan Railway, also said that there was nothing in the instrument to account for any failure; he considered that the release box must have been used. His theory was that Hollis had forgotten the train, and thought he had started it off, because the disc still indicated "train on line." He thought that he must have pulled back the lever prematurely. Then by some means he got to the release box and released the instrument. In reply to the Judge, witness said that in his opinion the negligence lay in not ascertaining whether the line was clear by personal observation.

The prisoner gave evidence on his behalf. He said that he had accepted the Willesden Green train, and it came into the station. He then offered it to Boggis, by whom it was accepted. He pulled off the starting signal, and immediately the disc

Digitized by Google

showed line clear. He then accepted the Neasden train from Finchley Road. Witness denied having in any way tampered with the release box. Mr. Jenkins, for the defence, in addressing the jury, said that the fact the prisoner was lying did not prove the case against him. Having regard to the numerous duties he had to perform, a signalman might well make a mistake. He had three or four discs to look after, and no less than seventeen movements to perform between each train.

Mr. Justice Bigham, in summing up, said that what the jury had to determine was whether the deaths of these people were due to the gross and culpable negligence of the defendant. His own opinion was that Hollis was careless, that he ought to have known, and if he had taken proper precautions he would have known that the Willesden train was in the station at the time he permitted the Neasden train to come into the station, and that the story he had told that day was a story of made-up excuses. Nevertheless, the best of us made mistakes and were negligent at times, but an occasional act of negligence, even though it resulted in death, ought not to bring upon a man the terrible consequences of a conviction for manslaughter.

The jury found the prisoner not guilty, and he was discharged.

Institution Glasgow Local Section.—The annual smoking concert takes place on Saturday, February 1st. Tickets (1s. each) can be obtained from the hon. local secretary, Mr. J. E. Sayers, 157 West George Street, Glasgow.

Paris-Morocco Wireless Telegraphy.—Wireless telegraphy has been established between Casa Blanca and Paris. On January 12th, at midnight, a telegram was received for the first time at the Eiffel Tower from Casa Blanca. The telegram was sent from the armoured cruiser *Kleber*, and announced the arrival of the vessel and the landing of the engineers. Henceforth there will be direct communication between Casa Blanca and Paris. The distance between the two places in a straight line is 1,900 kilometres, or 1,200 miles.

The Glasgow Tramway Accident.—Colonel Yorke, of the Board of Trade, held an inquiry at Glasgow, on Tuesday, into the cause of the runaway tramcar accident which took place on January 3rd, and which has resulted in the death of two persons and serious injuries to twelve other people. It was stated that the cars were inspected carefully every third night, and that this particular car was inspected on January 1st, and was found to be in perfect order. The conductor of the car said that he and the deceased driver took over the car at 5 p.m. on the afternoon of the accident, and had done three journeys previous to the car running away, and everything was in order. When they were about to commence the down-hill journey, they found the reversing handle would not come off. A timekeeper, another driver, and a motor inspector all tried it, but it remained fast. At the top of the steep hill in Hill Street, the car was under control, but a moment or two later the driver lost control. The conductor did not apply the hand brake, as he thought it might prevent the working of the magnetic brake, and he was not supposed to apply the brakes without instructions from his driver. He applied the brakes at Glasgow Cross, and managed to stop the car. It was afterwards demonstrated that the car was under complete braking control except for the reversing handle, and there was nothing in the condition of the car to account for the accident. The inquiry was closed, and Colonel Yorke will issue his report in due course.

Claim Against the London United Tramways, Ltd.—In the King's Bench Division on Monday, Mr. Justice Jelf delivered considered judgment in the case of Zick *v.* the London United Tramways Co., Ltd. This was an action by the plaintiff, a furniture dealer, of 84 Merton High Street, Wimbledon, for damages for trespass. On behalf of the Tramway Company it was maintained that they were authorised under an Act of Parliament to acquire the forecourt of the plaintiff's premises for the widening of the roadway. On May 25th, 1905, they served notice upon the mortgagees, who were in possession of the forecourt, for the purpose of their interest. On the date the plaintiff was not the occupier, and had no interest in the premises, but notwithstanding the service of this notice, the mortgagees purported to grant an interest to the plaintiff by means of an agreement of tenancy. Plaintiff contended that the defendants were liable to him for damages for trespass, and that he was entitled, under the Lands Clauses Act, to compensation for the compulsory taking of the forecourt as regarded his interest in the premises down to March 14th, 1903; and, on the other hand, the defendants submitted that after the date of the service of the notice to treat for the purchase of the forecourt the landlord could not create any fresh tenancy, and that the original tenancy had been surrendered by the operation of the law on the ground of the new tenancy. On the date of the alleged trespass, therefore, the plaintiff had no interest. The plaintiff did not hold under the original tenancy, and this new tenancy was invalid against the defendants. His Lordship held that the plaintiff had a *prima facie* title, and that the defendants had failed to displace it. He therefore gave judgment for the plaintiff for 40s. damages and costs, and declared that he was entitled to benefit under the Lands Clauses Act for his interest for the period ending March 14th, 1908.

REVIEWS OF BOOKS

The Patents and Designs Act, 1907. By James Roberts and H. Fletcher Moulton. 128 pp. 9½ in. by 6 in. (London: Butterworth & Co.). 4s.

IT is often said that an Act of Parliament can never be rightly interpreted until a few actions under its provisions have been decided in the law courts, and until one or two important cases at least have been the subject of appeal to the House of Lords. In the interval that must of necessity precede this complete interpretation, such books as the one under review are of extreme utility. Generally speaking, the Patents Act of 1907, which came into force on January 1st, 1908, is clearly drafted, but the authors of the present treatise point out some pitfalls by which the unwary may be entrapped, and some short clauses which it is of considerable importance not to overlook. Among these may be mentioned No. 33, which provides that although a patentee can always obtain an injunction against an infringer of his patent, he is not entitled to recover damages from any defendant who proves that he was not aware, and had not reasonable means of making himself aware of the existence of the patent. The remainder of this clause *may* be taken to imply that marking the patented article with the word patented or patent, together with the number and date of the patent, is sufficient notice to any potential "innocent" infringer; but the authors are not quite satisfied that this is the proper construction to be placed upon it. Moreover, this marking will obviously not enable the patentee to obtain damages for infringement which takes place before he has himself started the manufacture of the article in question, and it will thus be to his advantage to publish a notice announcing his invention in his technical journal, as the printed specification obtainable at the Patent Office will not necessarily be seen by all who are at work in the same direction. Fortunately, as the authors point out, the onus of proving absence of "reasonable means" of knowledge will rest with the defendant, who can be cross-examined if the case comes before the court.

On the question of compulsory licences, the authors point out that the provisions for these in the Act of 1902 proved to be practically a "dead letter." They do not commit themselves to any definite opinions as to whether the new Act will be more workable in this respect. Their comment on the section which provides for the revocation of a patent worked exclusively outside the United Kingdom is also guarded, but the meaning of the section is clearly explained, and, in the note to it, the interesting fact is stated that, out of 14,700 patents issued in 1906, 6,500 were granted to foreigners.

Those who are entering into agreements for the sale of patents or issue of licences should read the note in this book to Section 38, the section which makes it unlawful to make certain restrictions a condition of the sale or licence. It is pointed out that an extremely broad interpretation could be placed upon this, and, as it is an entirely new clause, particular attention should be directed to it.

We have said enough to show that Messrs. Roberts and Fletcher Moulton's book will be of great assistance to all who have to do with matters concerning patents. The book was published before the end of last year, and before the issue of the Patent Office rules under the new Act, and thus it happens, unfortunately, that the forms which the patentee and others have to make use of are all referred to by their old reference letters. This can, however, easily be corrected in the second edition of the work, which will doubtless soon become necessary.

Digitized by Google

"The Mechanical World" Pocket Diary and Year Book for 1908. 295 pp. 6¼ ins. by 4 ins. 60 illustrations. (Manchester: Emmott & Co.) 6d.

OWING to the introduction this year of a separate pocket-book dealing with electrical matters, it has been possible to omit the notes on electrical transmission of power, which formed a feature of previous editions of *The Mechanical World* Pocket Diary, and therefore to find room for a certain amount of fresh matter. This has enabled new sections to be added dealing with condensing plant, superheating, and friction clutches, while the information relating to reverberatory and reheating furnaces has been rewritten and extended. A few new tables have also been added. About half of the 130 pages of engineering information is devoted to matters connected with steam and steam engines, and the remainder, after short sections on gas and oil engines, relates to strength of materials, gearing, and other matters of general interest to engineers. Altogether the book, which for its size contains a good deal of useful matter, is an excellent sixpennyworth.

The Mechanical World Electrical Pocket Book for 1908. 176 pp. 6¼ in. by 4 in. 50 illustrations. (Manchester: Emmott & Co.) 6d.

THIS new addition to the many portable storehouses of information is a companion volume to the "Mechanical World Pocket Diary and Year Book," and is arranged in similar form, with engineering information at the earlier part of the book, while the latter portion forms a diary. The purely electrical section is mainly of a practical nature, and, on the whole, the proportion between the tabular, the obvious, and the descriptive has been well maintained, and the compilation being a new one does not suffer as many do from lack of courage on the part of the reviser as regards replacing the historical by the up to date. After the preliminary dealing with C.G.S. units, grouping of battery cells, the dynamo and motor are rapidly introduced, and a section deals with alternating currents in a brief way. Matter of a more practical nature follows, including a useful table of the approximate horse-power required to drive various classes of machinery, and hints on the management of dynamos and motors, with table of dynamo and motor defects and remedies; sections on wiring and instruments follow. Among the pages on electric lamps and lighting, various typical forms of arc lamp are described. Short sections deal with electric welding, electric cranes, and electric pumping. Following the electrical section are some notes of motive power and gearing, and some general tables.

Fowler's Mechanical Engineers' Pocket Book, 1908. Tenth edition. 675 pp. 6¼ by 3¾ in. (Manchester: Scientific Publishing Co.). Cloth 1s. 6d., leather 2s. 6d.

IN the latest edition of this popular annual for engineers, both general and electrical, the contents have been thoroughly revised, and it has been found necessary to leave out a good deal of matter connected with machine tools and processes, and buildings and materials, to make room for a much more extensive and comprehensive section on steam boilers and engines. A new section on pumps and pumping machinery has also been added. The volume exceeds previous editions by over 100 pages. The new section dealing with steam turbines forms a complete classification of all the principal types now in use, and a general description is given of the peculiarities of construction, the different effects of the vacuum, superheat, of initial steam pressure, and effects of load. This section will be of interest to engineers in charge of large lighting plants, where these types of plant have been installed. In addition to its utility as a general book of reference it is invaluable, treating, as it does, on almost every kind and detail of general engineering.

The Science Year Book, 1908: Diary, Directory, and Scientific Summary. 500 pp. 9¼ in. by 6 in. (London: King, Sell & Olding.) 5s.

THE 1908 issue of the "Science Year Book," edited by Major B. F. S. Baden-Powell, repeats the useful features of its predecessors, including the convenient form of calendar, directory of public institutions, scientific societies, &c. A quantity of useful tables and information are given, dealing to a large extent with astronomy, and this section has been revised and brought up to date. A brief summary of scientific progress during 1907 is included, but the wide field covered in a small space prevents this being more than very superficial. The list of technical journals contains several mistakes. Some additional notices have been added to the biographical directory. The latter part of the volume forms a diary with a whole page for each day.

Institution Manchester Local Section.—The meeting announced on the syllabus for January 21st, when Mr. C. H. K. Chamen was to have read a Paper on "High Voltage Transmission and Distribution," has, owing to unforeseen circumstances, been cancelled, and consequently no meeting will now be held on that date.

CORRESPONDENCE

OSRAM LAMPS FOR STREET LIGHTING.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to the description of Eastbourne Electricity Works appearing in your current issue, it is stated, on page 55, that Osram lamps are being used to replace alternating current arc lamps for street lighting. I believe this plan will be largely followed in the near future, so it would be very interesting, if you could give particulars and illustrations of the arc lamp-posts fitted with Osram lamps, and the precise reasons that brought about this change.

I look forward to doing the same here, because Osram lamps throw the light in a horizontal direction, so lend themselves with more advantage to outdoor lighting than interior lighting. Again, when made in 100 or 200 c.p. sizes the filaments will not be so fragile, and their cost ought to be comparatively less than that for the smaller sizes, as their manufacture would involve less delicate work.

Jan. 10th, 1908. MANAGER.

[Our correspondent has slightly misunderstood the arrangement for the addition of brackets to the arc lamp-posts at Eastbourne. The Osram lamps are merely used as half-night lamps, and do not replace the arcs. Osram lamps alone are, however, being increasingly used in the 100 c.p. size for street lighting. A notable example is Exeter, where this has been done for nearly two years, and the average life has been found to be about 1,200 hours. The 100 c.p. Osram lamp is now made up to 130 volts, and consumes 105 watts. A 200-volt 100-c.p. lamp will be on the market in a month or two. There is a little difficulty in obtaining quick deliveries of large quantities of 100 c.p. lamps, but this will disappear as soon as the arrangements for manufacture in this country are completed. We believe the 100 c.p. lamp is listed at 8s.—ED. E.E.]

German Government Wireless Telegraph Monopoly.—A Bill was introduced last week into the Reichstag amending the Telegraph Law of 1892. It provides that plant for the transmission of messages without the use of wires shall not be erected or worked except with the consent of the Government.

Faraday House.—The following special courses of lectures have been arranged:—"Electrical Legislation," by Mr. Robert Hammond; commenced January 15th; "Dynamo Design," by Professor C. A. Carus-Wilson, commencing January 20th; and "Secondary Batteries," by Mr. W. R. Cooper; commenced January 14th.

Telefunken System of Wireless Telegraphy.—A Reuter telegram from Nauen states that great improvements have been made in the station there. The experiments already made this year show quite exceptionally good results. Telegrams have been received at Nauen from a small portable military station at Kornenburg, near Vienna, whilst the steamship *Cap Blanco*, of the Hamburg South American line, on the voyage from Hamburg to Buenos Ayres daily received telegraphic news from Nauen. The last telegram reached her at Teneriffe, when she was eight days out from Hamburg. The distance to Teneriffe is about 2,300 miles.

Disregard of Tramway Regulations.—A sequel to the tramway accident at the junction of City Road and Old Street on December 28th (ELECTRICAL ENGINEERING, January 2nd, p. 18) was the appearance before the magistrate at Old Street police court on Saturday, of the driver of the electric car which smashed into a horse-drawn car. The charge preferred against him was that he crossed the City Road at this point at a speed of about 10 miles per hour, whereas the Board of Trade Regulations stipulate a compulsory stop there. The defendant, in giving evidence on his own behalf, said he applied the magnetic brake according to directions when approaching the crossing in question, but the brake failed to act. Before he could apply the hand brake he had collided with the horse car. The magistrate came to the conclusion that there had been some carelessness on the part of the driver, and fined him ten shillings and two shillings costs.

Telegraph Traffic.—The West India and Panama Telegraph Company have again been unfortunate, as we have to record the interruption of their cable between Trinidad and Demerara on the 8th instant. This will be repaired by their own steamer, the *Henry Holmes*. The French company owning the cables between Paramaribo and Cayenne and San Domingo and Curacao also have to undertake repairs, as the latter cable failed on the 11th, but was again carrying traffic on the 15th. Since the Venezuelan Government closed their Curacao-Coro and Curacao Le Guayra sections, they have had to transmit telegrams to Curacao, and there post them to addresses in Venezuela, telegrams having to be fully addressed for this purpose. The Paramaribo-Cayenne cable, like its sister the Cayenne-Salinas cable, is sometimes interrupted for a year or more at a time. The French company also have their own repairing vessel on the spot. No news has yet come to hand of the repair of the Brest-Dakar cable, in connection with the repair of which great difficulties are being experienced. The *via* Fao route has also again been in difficulties, and was inoperative on the 11th inst.

COST OF ELECTRICAL POWER FOR INDUSTRIAL PURPOSES

A PAPER read by Mr. John F. C. Snell before the Institution of Electrical Engineers last Thursday dealt with the commercial aspects of electric power supply from the engineer's point of view. In introducing the subject, the author enunciated four axioms :—

1. There is generally a critical load factor and size of plant within which no outside supply can hope to compete with a user's local plant; *i.e.*, at and beyond this critical point a user can produce more cheaply from his own plant.
2. Whatever the pressure of transmission, or whether by underground cables or overhead lines, there is a real limit to the economical radius of distribution from any power station, which is much less than is usually advanced by power company promoters.
3. Minimum outlay of capital, which is indispensable in power supply, can only be obtained in the power house by the centralisation of large units. But this can be neutralised in any particular case, and the capital per kilowatt raised beyond the critical value, by attempting tranmission over too great a distance.
4. Successful power supply depends upon—(*a*) the geographical positions of the user and supplier, because the capital cost of the supplier's plant, *plus* transmission and transformation, may exceed the capital cost of the user's own plant; and (*b*) the resultant diversity factor arising from multiplicity of industries. Arising from this latter point, great care has to be exercised in the districts where the industries are all practically of one nature, for the diversity factor will be almost *nil* in such cases.

Referring briefly to lighting, Mr. Snell pointed out that the effect of power supply super-added to lighting supply must of necessity reduce the general cost of production, because of the greater resultant diversity factor and consequent improved load factor. In this country he estimated that 2d. per unit may eventually be reached, as an average cost of lighting units. This reduction of price, he added, cannot be compared with the importance of a probable reduction of energy per candle-power from 4 watts to, say, 1·5 watts. Moreover, the price of lighting must always be considerably in excess of average power prices, both because of its lower load factor and also of the greater cost of low-tension distribution systems and requisite service connections

In the first part of his Paper the author examined the alternative sources of power supply to that furnished by an electric power company or other large central electricity supply authority. Table I. sets forth the cost at various load factors of gas engines supplied with town gas, suction gas engines, oil engines, and small local steam plants of from 20 to 100 h.p. with generators and auxiliaries. These figures have been obtained from actual users; they are not merely test figures, which afford no real criteria of the commercial working of such plants, nor are they figures of obsolete engines, which would be unfair to take as a basis.

TABLE I.

Ascertained Cost of Power per Unit Generated for Independent Installations up to 100 H.P.

Annual Load Factor	Equivalent Hours per Annum.	Town Gas at 2s. per 1,000 cub. ft.	Suction or Producer Gas.	Oil.	Steam.	Average Costs.
Per cent.		d.	d.	d.	d.	d.
10	876	1·423	1·520	1·286	1·322	1·388
15	1,314	1·210	1·270	0·972	1·031	1·121
20	1,752	1·090	1·040	0·813	0·876	0·954
25	2,190	1·007	0·904	0·715	0·806	0·879
30	2,628	0·944	0·812	0·650	0·705	0·778
35	3,066	0·892	0·744	0·600	0·646	0·720
40	3,504	0·844	0·694	0·563	0·598	0·675
50	4,380	0·791	0·625	0·511	0·542	0·617
60	5,256	0·745	0·576	0·475	0·498	0·574
70	6,132	0·706	0·540	0·448	0·460	0·538
80	7,008	0·670	0·514	0·426	0·429	0·500

Town gas is taken at an average price of 2s. per 1,000 cub. ft. In the case of suction or producer gas engines, anthracite coal, it is assumed, costs 22s. per ton, or small peas 10s. per ton; the price of oil is taken at 42s. 6d. per ton. For water an average price of 6d. per 1,000 gallons is reckoned; repairs and lubricating oils are taken from actual figures. The depreciation and interest on capital outlay are taken throughout at 10 per cent. These are the real figures with which manufacturers debit themselves, but it is pointed out that in nearly every case there is no proportionate charge for supervision or general establishment charges, or for rating. Attendance is frequently not debited to the cost of power, and, therefore, on all points the figures given are decidedly fair to these sources of power, and are even somewhat unfair to electricity supply.

Table II. sets out comparative figures for larger and less frequent installations of 100 to 500 h.p.

TABLE II.

Ascertained Cost of Power per Unit Generated for Independent Plant from 100 to 500 H.P. Installed.

Annual Load Factor.	Equivalent Hours per Annum.	Suction or Producer Gas.	Oil.	Steam.	Average Costs.
Per cent.		d.	d.	d.	d.
10	876	1·273	1·007	1·086	1·122
15	1,314	0·944	0·778	0·811	0·844
20	1,752	0·760	0·656	0·673	0·690
25	2,190	0·670	0·584	0·590	0·615
30	2,628	0·596	0·536	0·534	0·555

80	7,008	0·358	0·366	0·357	0·360

In the second part of the Paper are given actual statistics of independent tests (mostly by the author himself) of different industrial plants, and a comparison shows that the figures in Tables I and II are, if anything, on the low side.

Graving Docks.—In a certain electrically driven pontoon, which is capable of berthing vessels up to nearly 4,000 tons displacement, the pumps are four in number, and are electrically driven centrifugal pumps, each 18 in. diameter. The following are official figures obtained when actually docking a vessel of 2,600 tons :—

Tons of water pumped	3,875
Maximum head on pumps	27 ft.
Average head on pumps	16 ft.
Time taken to empty	25 minutes
Cost of power supply (outside source) ...	1·375d. per unit
Number of units consumed	123

The actual total cost per ton of vessel docked was :—

Power	0·064d.
Wages, &c.	0·100d.
Interest and depreciation at 10 per cent.	0·159d.
	0·323d.

Another case taken for comparison was that of a graving dock driven by two gas engines, 40 h.p. each, each driving horizontal centrifugal pumps, each 21 in. diameter, with a capacity of 9,320 gallons per minute, with a maximum head of 28 ft. and an average head of 17 ft. The following are the data when docking a vessel of 1,760 tons :—

Tons of water emptied	10,632
Time taken to empty	128 minutes
Cost of gas per 1,000 cub. ft.	1s. 6d.
Gas consumption	4,600 cub. ft.

The actual cost per ton of vessel docked was :—

Power	0·046d.
Wages, &c.	0·412d.
Interest and depreciation at 10 per cent.	0·587d.
	1·045d.

The Paper continued : It will be observed in this comparison that the graving dock represented a much longer run and a better load factor, and yet the cost of docking by gas-driven plant was three times that of electrically driven plant. It is fair to say, however, that the electrically driven plant is of recent design, whereas the gas plant cannot be said to be modern. The author stipulated that during "peak" loads in the restricted winter months, only one-half of the pumps should be worked, the docking on these occasions, therefore, taking approximately twice the usual time. The occasions when this restriction had to be enforced were few.

In the above-cited gas installation, the price being so low per 1,000 cub. ft., it is improbable that any great economy would have been gained from an independent suction or gas-producer plant.

Dock installations require an extensive system of jib and other cranes, capstans, and other auxiliaries. These, however, are so demonstrably better than hydraulic cranes and capstans, both in speed of working and annual cost, that it is unnecessary to dwell upon them The author has been associated with an exten-

Digitized by Google

sive application of 3-phase power to travelling jib cranes and capstans, which have been both successful and economical. It it found that plant of this description has a very low annual load factor, consumes but few units, and brings in a very small revenue. Care has, therefore, to be exercised in fixing prices for such a supply.

Shipyards.—A comparison was next made by the author of the actual costs of gas-driven and steam-driven local plant of two neighbouring shipyards. Both the yards were electrically equipped, the local generating plant in the one case being driven by gas engines supplied from the town mains and in the other by modern steam engines.

In the gas-driven plant the following data were given by the authorities themselves, and carefully checked by the author :—

Duration of test, 4 months; ordinary working conditions.
Number of gas engines, 3.
Total b.h.p., 360.
Total kilowatts, 225.
Belt-driven shunt-wound dynamos, 230 volts.
Maximum load recorded on switchboard, 207 kw.
Total units generated, 83,125.
Load factor, 14 per cent.
Cost of gas, 1s. 6d. per 1,000 cub. ft.

The cost of power actually ascertained (but excluding any item of supervision, general establishment charges, or rating of machinery) was as follows :—

	£	s.	d.
Gas, 3,000,828 cub. ft.	225	0	10
Engine and dynamo oils	24	1	7
Water at 6d. per 1,000 gallons	2	0	0
Waste and stores	5	9	10
Repairs (material	5	16	8
Attendance and repairs (labour)	84	12	1
Interest and depreciation at 10 per cent.	60	0	0
Total cost for 4 months	£407	1	0

representing a total cost per unit of 1·173d. It is only fair to point out that the item "attendence and repairs (labour)" is an excessive one, but the figures are, nevertheless, a statement of fact.

Attention is also called to the large gas consumption, which amounted to 36 cub. ft. per kilowatt-hour, a large figure, even on so low an annual load factor as 14 per cent. The plant load factor was 48 per cent.

In the case of the neighbouring independent steam-driven plant in a combined shipyard and engine works, the following figures were obtained :—

Duration of test, 1 year; ordinary working conditions.
Four triple expansion condensing steam engines, high speed, enclosed, each 250 h.p. Total, 1,000 h.p., 672 kw.
Cooling towers.
Boiler pressure, 160 lb. No superheat. Marine boilers, close to engines.
Maximum load observed, 504 kw.
Total units metered at switchboard, 891,655
Load-factor, 22 per cent.
Class of coal used, small at 11s. per ton.
Lb. of coal per unit generated, 7·3.

Cost of generation :—

	£	s.	d.
Labour	665	0	0
Coal, 2,924 tons at 11s.	1,608	11	11
Feed water	59	0	6
Circulating water and make-up	31	19	6
Lubricating oils	58	8	5
Repairs and general stores	141	2	10
Interest and depreciation at 10 per cent.	1,042	6	4
	£3,606	9	6

representing a total of 0·97d. per unit generated.

A shilling per ton rise or fall in the price of coal per ton would have raised or lowered the price per unit by 0·39d., or 4 per cent. The condensing appliances were somewhat faulty, and better figures would have been obtained with an improved vacuum, and with superheat.

In another case of an engine works driven by modern enclosed engines, representing a total of 1,000 h.p. with a load factor of 24 per cent., and where there were both superheat and a good vacuum, the author obtained the total figure of 0·71d. per unit metered at the switchboard.

In the above case 0·97 per unit generated, even with small coal, is admittedly a high figure, and could be reduced on test. The author's experience, however, leads him to think that whatever may be the results obtained on test—whether with gas or oil engines or steam—the consumers do not give that attention to the upkeep of their plant which might be expected, and the figures quoted are really reasonable average figures obtained in practice, and this is an argument in favour of generating plant being in expert hands in a centralised power station.

Paper Mills.—The following are particulars of a paper mill which came under the author's notice. He points out that the figures could undoubtedly have been improved upon, as some of the boilers were low pressure (80 lb.), and could have been replaced with advantage by high-pressure boilers. On the other hand, this paper mill is a successful one, and typical, the author believes, of very many throughout the country which offer a field to electrical enterprise :—

Duration of test, one year; ordinary working conditions.
Number of engines, 25. Total b.h.p., 1,820.
Total cost consumed for power driving, 17,680 tons.
Average horse-power, 1,760.
Running hours per annum, 7,000.
Total h.p.-hours, 12,320,000.
Annual load factor, 79 per cent.

The cost of power was as follows :—

	£
Coal	9,724
Oils and stores	156
Wages	1,524
Repairs	700
Interest and depreciation at 10 per cent.	2,730
	£14,834

representing 0·29d. per h.p.-hour, or an equivalent of 0·41d. per unit generated. In paper mills, boilers have to be installed in any case, and much coal used, for boiling the esparto grass, heating and drying the pulp, and heating the calenders. In this case, out of a total of 26,000 tons used per annum, no less than 8,320 tons were used for heating and drying purposes, the balance being required for power.

The works in question have in addition to the grass boilers, washers, and calendering machines, all of which require live steam, paper-making machinery, half-strip machines for straining, beaters, cutting and rolling machines. There are thus a number of machines which are usually at some distance from the main drive. These auxiliaries, which represent from 10 to 15 per cent. of the total power, and are usually from 10 to 30 h.p. each, could certainly be driven more economically by electrical means, either from generators driven from the main mill engines, or supplied independently from an outside source.

Works of this class have so high an annual load factor, and, in the author's opinion, are of such a size and nature that it becomes a difficult problem for a central power supply (unless of very large dimensions) to compete successfully with the manufacturer's own plant, more especially as the very nature of this day-and-night load does not permit of any improvement of the general diversity factor at the power station.

The author calculated that this consumer could have reduced the annual cost by 20 per cent. by installing high-pressure boilers, and by substituting motors for the wasteful steam engines situated at the outskirts of the mill. This would have reduced the cost of the manufacturer's own power from his own plant to an equivalent of 0·33d. per unit.

Jute Mills and Cotton Mills.—A jute mill is another difficult class of factory for the successful competition of electricity, and is very similar to cotton and other textile mills. The running hours are usually about 2,750 per annum, and the load is practically constant. This represents an annual load factor of 32 per cent., but a plant load factor of 92 per cent.—thus the cost of power is exceedingly low.

In an actual modern mill having a total horse-power of 990, the annual costs were as follows :—

	£
Coal	1,444
Water	124
Wages and repairs	720
Interest and depreciation at 10 per cent.	1,350
	£3,638

which is equivalent to 0·37d. per h.p.-hour. On an annual output of 2,284,500 h.p.-hours, this is equivalent to a price of 0·48d. per unit.

In this class of mill the main engines represent about 83 per cent. of the total power installed, the remaining 17 per cent. being made up of auxiliaries scattered about the place, which it would certainly repay to equip with motors, not only because of their isolation from the main drive, but also because the auxiliaries generally require to run for longer periods than the main engines in order to keep pace with the output from the spindles, spinning frames, and general machinery. It is interesting to know that in a mill of this description the shafting losses represent 25 per cent. of the total power. Regularity of

Digitized by Google

speed is absolutely essential, and a 3-phase motor is the most beautiful application possible, not only giving regular speed, but also freedom from fire risk, which is important in this class of works.

Mr. Wilson,* in 1905, quoted some figures of a new mill engine, whose full-load diagram was 738 i.h.p., and the light-load friction diagram 300 i.h.p., showing an apparent efficiency of only 59 per cent. In such a case there must obviously be a good opportunity for electrical driving. He went on to say that the total cost per i.h.p.-year comes out to something of the order of £2 5s. to £2 10s. for large mills, *i.e.*, equivalent to £3 to £3 7s. per kilowatt-year, and in the case of small mills from £3 7s. to £4 7s. per kilowatt-year. Although he does not give the figure, this really means that, based upon the usual running hours of 2,700 per annum, the cost per unit ranges from 0·257d. to 0·287d. for large mills, and from 0·287d. to 0·375d. for smaller mills. These figures appear to the author to be too low. It is obvious, therefore, that only by the greater efficiency of electrical driving, *i.e.*, by competing with the cost per useful horse-power at the spindles, &c., can these mills be successfully dealt with by electrical power. If the 59 per cent. efficiency mentioned above is, however, a usual figure, there can be no question that the cost of providing motors could be successfully met.

In the investigations of jute mills the author has not been able to make the friction losses greater than 30 per cent., and information on this point from engineers who have to deal with mills will be of value.

Collieries.—Several figures have been quoted recently as to the cost of independent plants at collieries, but the author may be excused for quoting the following figures again in order to complete this list of possible large power users.

In a Paper† read before this Institution, Mr. C. P. Sparks quoted the following figures for the installation at the Powell Duffryn Collieries :—

Power house, 3,000 kw. installed.

Average horse-power of motors at work—

Haulage	2,900	h.p.
Winding	180	,,
Fans	380	,,
Pumps	340	,,
Screens	240	,,
Auxiliary motors	480	,,
	4,500	

Total cost—

Power house	£11·5
Distribution and sub-stations	2·6
	£14·1 per kw. installed.

Annual output in units, 4,800,000.
Average load factor, 36 per cent.
Coal consumption per unit, 3·7 lb.
Cost of coal, 5s. per ton.

The cost of power was as follows :—

Running cost	0·18d
Interest and depreciation, 10 per cent. on £34,000	0·17d.
Total cost	0·35d.

In such a case, Mr. Snell continued, it would appear to be impossible for an outside power supply to compete successfully with the colliery's own plant; for reference to the schedule of charges in Table XIII. will show that for an annual load factor of 36 per cent. a price of 0·47d. should be obtained for transformed alternating current as against 0·35d. obtained by the local plant. It is estimated that this local cost will be reduced to below 0·3d. as the installation becomes completed, and as the load factor rises to 46 per cent., which then will make competition from outside quite impossible. While this is true, however, of so large a local plant as 3,000 kw., it would not, of course, apply to smaller collieries involving an installation of, say, 1,000 kw., in which case the power station would no doubt successfully compete as the capital and standing charges would raise the cost materially.

Steel and Other Large Works.—The remarks that have been previously made upon the cost of supply to engine works apply generally to works of this description. Annual load factors of from 20 to 25 per cent. are obtained, and the prices are found to range between 0·7d. and 0·6d. per unit. Therefore, on referring to the schedule of charges, it will be seen that a large power company could compete successfully with works of this description. Of course, some deduction must be made in certain cases for the utilisation by steel works of their blast furnace gases, which are utilisable in gas engines. The load factor of such works can be improved by the adoption of some such system as the Ilgner and by kinetic storage, and thus prevent the abnormal fluctuations in the loads of the rolling mills. Although this system is costly to instal, it considerably reduces the amount of generating plant which would otherwise be required to meet the "peak" loads, and the additional cost of such a levelling-out system will be more than repaid.

Rope-Making Works.—In the case of a rope-making works which the author investigated it was found that the cost represented practically 0·5d. per h.p.-hour, equivalent to 0·67d. per unit, the running hours being 2,700 per annum, and the load being practically constant. The annual load factor being 30 per cent., and the equivalent price in the schedule quoted by the author being a little over 0·5d. per unit supplied, it would obviously be possible to supply such works from an outside source.

Breweries.—The author investigated the driving of a brewery equipped with modern plant. The prime movers were gas engines, developing in all 194 h.p.

The following were the annual costs :—

	£	s.	d.
Gas at 1s. 6d. per 1,000 cub. ft.	338	14	9
Wages and repairs	516	12	4
Oils and stores	111	4	0
	£966	11	1

Interest and depreciation not given.

The cost of driving the shafting amounted to no less than £270 per annum : thus the net cost of useful power amounted to £696 11s. 1d. The shafting was very lengthy, but owing to the positions of the various machines this was unavoidable, and explains the reason of so great an annual loss. The wages and repairs are certainly very high indeed, but, nevertheless, the figures are the real figures given to the author by the authorities of the brewery.

The electrical cost after conversion was as follows :—

	£
66,550 units at 1·5d.	416
Oils and stores	20
Wages and repairs	78
Interest and depreciation on new plant	112
	£626

or 2·25d. per unit.

In addition there was a great deal of saving of room by clearing out much of the shafting, and absence of vibration and noise and of dirt from the oil cups of the shafting.

Saw Mills.—The author was responsible for the electrification of a small saw mill which had been driven by steam engines at a cost of over 2d. per h.p.-hour, or, say, 2·6d. per unit. Seven motors were installed, ranging from 4 to 50 h.p. each, with a total horse-power of 179. After one year's run it was ascertained that the total consumption was 50,785 units. The suppliers found the static transformers and high-tension switchboard, but the low-tension switchgear and fireproof transformer chamber were found by the user. The cost to the consumer was as follows :—

	£	s.	d.
Electricity	264	10	2
Oils and stores	9	3	4
Interest on sub-station building	12	0	0
	£285	13	6

or 1·35d. per unit, exclusive of capital charges on motors and wiring.

Miscellaneous Works.—Turning now to the general smaller power users within towns, Mr. Snell continued, there is no question that it is possible to supply these successfully from a central source, as none of these works are likely to exceed the running hours of, or the load factor from, a saw mill and joinery works when the annual hours are 2,700 and the load fairly constant; and it has been demonstrated that the latter works can be supplied economically from a central source, and at a cheaper rate than it can be generated by local plant. In each case of small power supply the author has found it quite easy to compete successfully with local plant, whether steam or gas driven, when each case is carefully tested and dealt with. Moreover, in works of this nature, space is of the utmost importance, and the ability to switch the outside supply on or off at will constitutes a very great boon to the user.

* *Journal of the Institution of Electrical Engineers*, p. 757, vol. 34, 1905.
† *Ibid*., p. 477, vol. 36, 1906.

Digitized by Google

In Sunderland, at the time of the last census for which the author was responsible, and omitting the large engine works and shipyards, there were 587 motors, representing a total horse-power of 1,634, or an equivalent to 1,220 kw. The maximum demand on the station plant was only about 500 kw. There was thus a diversity factor of 2·4, the total units for the year being 404.999, or 332 per kilowatt installed. This represented a consumption of 810 units per kilowatt demanded for this particular load, and was thus under an average load factor of 10 per cent.

Table III. will be of value as giving statistical information of the horse-power, which may be estimated for works of various kinds.

TABLE III.

Description of Works.	H.P. Installed.	Number of Persons Employed.	H.P. per Capita.	Annual Units.	Units per Capita per Annum.

Paper mill	1,820	410	4·43	—	—

This will be found useful in prospecting any district, as, short of a complete census of the actual power installed, the only way is to compute the horse-power per capita of the several factories. It is interesting also to note the relation of the maximum demand in works to the motors installed, though such figures are difficult to obtain, as manufacturers are not generally inclined to give this information. The particulars in Table IV. are somewhat limited, but perhaps a discussion on this Paper will educe particulars of other classes of works which must be of general interest to the industry.

In the preparation of particulars for the recent London County Council Power Bills, the author and his colleagues ascertained that in the area of Greater London alone there are factories utilising altogether some 400,000 h.p., while in the evidence

TABLE IV.

Description of Works.	1. H.P. of Motors Installed.	2. H.P. of Transformers Installed	3. Maximum Demand H.P.	— Ratio $\frac{2}{1}$	— Ratio $\frac{3}{1}$
Shipyard	1,576	1,200	900	0·76	0·57
Engine works ...	5,538	3,200	2,400	0·57	0·43
Printing	37	—	37	—	1·00
Saw mills	179	200	140	1·12	0·78

brought forward in support of the Administrative Company's Bill, 1906, this figure was given as 535,742 h.p., of which only 29,053 h.p. was then supplied from electrical undertakings. That a very great impetus has been already given to the adoption of electrical power there is no question. In the town of which until recently the author was engineer, within four years the power load connected had grown from 2,000 to over 10,000 h.p.

A modern power station of important magnitude and favourably situated can be now equipped completely for £12 or £13 per kilowatt installed. One cannot imagine that this figure is likely to be reduced materially. A transmission system in which the cables are designed to allow for diversity of loads supplied over a large area could be laid down also for £12 per kilowatt supplied; thus the all-round cost of an electrical installation is some £25 per kilowatt, excluding transformers.

The author's experience obtained in providing and equipping a large number of sub-stations is given in Table V.

In new ground, of course, it is in the interest of every one concerned to use static transformers, not only because of their lower capital cost, but also because of the minimum space required by them, the absence of attendants, and the saving in running stores and repairs. Incidentally, the automatic arrangement of Mr. Berry should prove useful in factories, for, as a general rule, either offices in works require to be lit after the main power is shut down, or small repairing shifts are required at night, and lights required for watchmen in case of outbreaks of fire. The transformer losses in the larger sizes then become an important item if allowed to continue on circuit to supply these trivial loads.

TABLE V

Cost of Static Transformer Sub-stations.

Kilowatts Installed.	Kilowatt Demand.	Cost of Buildings, Plant, and Switchgear.	Cost per Kilowatt Installed.	Cost per Kilowatt Demand.
150	100	£ 501	£ 3·34	£ 5·01
900	600	1,557	1·74	2·59
		Average ...	£2·54	£3·80

Cost of Rotary Sub-stations.

Kilowatts Installed.	Kilowatt Demand.	Cost of Buildings, Plant, and Switchgear.	Cost per Kilowatt Installed.	Cost per Kilowatt Demand.
650	400	£ 3,238	£ 4·98	£ 8·09
1,000	750	5,553	5·55	7·40
1,400	1,150	5,968	4·26	5·19
		Average ...	£4·93	£6·89

There are, however, many large works which are already electrified and supplied from their own plant. If direct-current motors are already installed, then a rotary sub-station must be put in at a greater cost to both supplier and user. It then becomes a matter for calculation to the latter whether it will better pay him to replace his existing motors by 3-phase, or to pay a necessarily higher annual sum for transformed and converted current. Here, again, in power supply the difference between an all-round 85 per cent. efficiency for rotaries, and 95 per cent. for statics, cannot be overlooked.

The total capital cost per kilowatt installed at the power house, therefore, from the power station up to and including the user's sub-station, will be as in Table VI.

TABLE VI.

Cost of Stations, Transmission Systems, and Static Sub-stations.

Capacity of Sub-station.	Cost of Power House per Kilowatt	Cost of Transmission System per Kilowatt.	Cost of Static Sub-station per Kilowatt.	Total.	Equivalent Cost at 1·66 Diversity Factor.
100–250	£ 13	£ 12	£ 3·33	£ 28·33	£ 18·33
250–1,100	13	12	1·75	26·75	16·75
			Average	£27·54	£17·54

Cost of Stations, Transmission Systems, and Rotary Sub-stations.

Capacity of Sub-station.	Cost of Power House per Kilowatt.	Cost of Transmission System per Kilowatt.	Cost of Rotary Sub-Station per Kilowatt.	Total.	Equivalent Cost at 1·66 Diversity Factor
250–500	£ 13	£ 12	£ 5·20	£ 30·20	£ 20·20
500–1,500	13	12	4·26	29·26	19·26
			Average	£29·73	£19·73

These are, however, not the real figures to take when fixing a schedule of charges, because of the influence of diversity factor. This figure will be found to vary in different localities and among different industries. For instance, the ratio of the sum of maxima observed at the several sub-stations in Sunderland to the actual observed maximum demand on the plant supplying them was only 1·25, because the industries supplied were very much of the same nature; but it is more general to find a diversity factor of 1·66 in a more varied set of industries. The author is here speaking of the diversity of sub-station maximum loads compared with the observed maximum at the power station. Of course, the ratio of the sub-station load to the horse-power of motors installed in factories is really only about 50 per cent., representing a diversity factor of 2.

Digitized by Google

The statistics in Table VIA. may be useful :—

TABLE VIA.

	Total Kilowatts Installed.	Maximum Load Observed.	Ratio.	Diversity Factor.
Engine works	1,574	750	0·50	2·00
Engine works	1,090	434	0·40	2·25
Shipyard	310	200	0·66	1·50
Shipyard	950	450	0·47	2·12
Shipyard	357	175	0·50	2·00
Dock cranes, etc. ...	223	56	0·25	4·00
Saw mills	135	88	0·65	1·50

Obviously the capital cost per available kilowatt at the power station depends very much on the diversity factor, for the figure which may be taken as the assessable value of a power house and transmission system in the one case is £25÷1·25, or £20; and in the other case, £25÷1·66, or £15. Thus the total capital cost of plant, including a static transformer sub-station, will be either £22·54 or £17·54, and the total cost of a rotary sub-station £24·73 or £19·73, according to size.

It is obvious that some differentiation must be made between a low-tension supply of direct current and one of alternating current when one is preparing a schedule of charges, for at any load factor, say 20 per cent., the capital charges as between the two systems represent an additional 5 per cent. for the rotary over the cost of static sub-stations, without counting the addition to standing charges from attendance or from stores, &c., required by the former type or the less efficiency of rotary sub-stations.

It is of little use straining to reduce the capital outlay per kilowatt on the power house and distribution system, if one is going to sink an additional £2 or £3 per kilowatt on rotary sub-stations, so that there can be no doubt as to the wisdom of applying static sub-stations to all industrial purposes, wherever possible; and it is useless designing a highly efficient power house and transmission system if one throws away 10 per cent. at least in a sub-station. Space is of great importance to the manufacturer, and so much less is required, of course, by the static sub-station (about 0·8 sq. ft. per kilowatt installed, as against 1·75 sq. ft. required in a rotary sub-station). Power suppliers will do well, therefore, so to arrange their transmission system that works requiring 100 kw. or more shall be supplied whenever possible from their own local static sub-stations. If the works can be grouped, a centralised sub-station can be put down with overhead low-tension mains to each of the works supplied from it, so as to minimise expenditure on this item.

In the published tables of 1907 of the London County Council Electric Supply Bill, a differential tariff was adopted by the advising engineers to the Council. Of course, the lighting charges will represent a curve higher at every point than the power curve. This is obvious from the fact that one does not get the same diversity factor with lighting consumers as with power consumers.

It is a comparatively easy matter to estimate closely the cost of a power station, and even of the transmission or distributing system and sub-stations; and the one factor which is really unknown, but upon which the scale of charges so much depends, is this diversity factor. 1·66 may be all right in one district, but if applied universally will certainly lead to trouble. Therefore, in fixing maximum scales it is wise always to base the *maximum* rates upon a diversity factor of unity, and the actual commercial scales which will thereafter be charged will, no doubt, depend upon the experience which is gained by the supplier after some years of working.

To some extent the load factor can be raised artificially and by arrangement. In one locality the author got manufacturers to modify their dinner hours, so that instead of all shutting down synchronously, approximately half shut down from 12 to 1 p.m., and half from 1 p.m. to 2 p.m. Some power companies are also arranging to supply chemical works, in some of which certain processes can be shut down during restricted hours.

The severest handicap to power supply from existing London and provincial stations—whether administered by companies or municipalities—is, in the majority of cases, their present high captal cost per kilowatt. It is true that with each extension this figure is reduced; still, it will be found very difficult, especially in the case of London undertakers, to reduce their total much below £60 per kilowatt, or, in the case of large provincial stations, to reduce their capital much below £40 per kilowatt, or smaller stations to £50, taking into account all existing capital outlay. This is where the modern power company comes in with the benefits of latest electrical practice, much cheaper buildings, larger and cheaper units of plant, and, generally, an altogether lower cost per kilowatt. Even with a power company, however, there is a danger that the capital, while minimised in the power house, may be unduly raised by the cost of transmission over too great a distance. The present capital expenditure per kilowatt on London municipal systems averages £93, and London company stations £103; while the present expenditure on provincial municipal stations is £70·8, and provincial companies, £90.

Table VII. shows the average prices charged by existing undertakings for power in 1906 within the area proposed to be covered by the various London Power Bills. Side by side are given the figures which ought to have been charged, assuming that the average load factor of power supply is 20 per cent. and the diversity factor 1·66. The average load factor will certainly not be more than 20 per cent.; and if it really has a lower value, then the author's criticisms tell so much the more against the present suppliers. It will be seen that in the case of the South Metropolitan Company the average price charged for power was 1·048d. per unit, whereas the real charge should have been 2·367d.; or take the Westminster Company: the charge was 1·83d., whereas it should have been 2·4d. Or take the municipal cases: Battersea, where the average charge is 1·5d., and the real charge should have been 1·975d.; Islington, where the charge was 1·37d. and the real charge 2·2d.; or St. Pancras, average charge of 1d., and the real charge should have been 1·83d. This means, obviously, that the power user is being supplied by these undertakers at the expense of their lighting consumers, who are paying an unduly high rate for their supply, or in the case of certain London municipalities at too high a cost of public lighting. This system may do very well where there is only a small amount of power to be given, and where the proportionate revenue is only a small fraction of the gross receipts; but let there be a big increase in the amount of power supplied at the same rates (and despite its effect in the general reduction of generating costs), it will be found then that the total receipts are not commensurate with the total costs, and the result will be an unsuccessful undertaking.

That there is only one way in which to deal with the London problem must be obvious to all engineers—that is, through some means, a large power station must be erected at a minimum cost, which, without prejudicing the present capital involved in the existing undertakings, will enable electricity to be supplied for all purposes at considerably less rates than now obtain. The capital sunk in existing undertakings cannot, of course, be ignored; it constitutes a dead-weight upon electrical supply in London, which will remain until this original capital shall have been redeemed. That cannot be for several years yet, and, therefore, the only compromise is to provide this supplementary low-cost station to co-operate with and assist those already in operation.

The effect is apparent even now, for the more successful companies, whose able administration cannot be questioned, find that since they have had to reduce their scales of charges they are not able to declare the same dividends as they were able to do a few years back; and this effect is likely to get worse rather than better. Or take the case of some London municipalities who have so very foolishly contented themselves by merely putting aside a sinking fund on a 42-years' basis, well knowing that their plant could not possibly exist for so long a time. It will certainly be admitted that twenty-five years is the maximum period which engineers would be wise to allow as the equated life of their plant. These municipalities have, therefore, a good deal to make up for past years, and they simply cannot put themselves in a sound financial position and at the same time offer their power users such a low scale of charges as will promote a large revenue from the sale of electricity for power. They, again, can only carry out the duties imposed upon them by their orders by a wise co-operation with some central scheme.

Table VIII. shows the true cost of production in some of the larger provincial municipal stations. These figures are based upon the official published results for 1906 or 1907. In every case the capital charges have been taken as requiring interest at an average rate of 3½ per cent. and depreciation at 2¾ per cent; that is to say, 6¼ per cent. has been taken upon the total capital expenditure, and added to the costs.

be able to supply such a consumer successfully at not more than 0·8d., or a reduction of 30 per cent. This is the result of the larger stations. And if one turns to the smaller provincial stations, which are given in Tables X. and XI., the results are very much the same, as the larger districts will almost certainly have a higher diversity factor; therefore the author

suggests that he may be quite wrong to assume the same co-efficient in both tables. These figures, of course, will improve as years go on—or at least it is hoped so—because with extensions of the stations, as has been said before, the capital cost per kilowatt should be reduced. This will apply with more force to the larger systems. But a warning should be noted by station engineers that the future will bring, in all probability, a very large proportionate increase of low-price power units, and with improvements in lamps and their reduced energy consumption, the proportionate lighting units may even fall below their present figure.

The author has purposely taken only 6¼ per cent. in the case of the large undertakings for capital charges and depreciation, and 10 per cent. in Tables I. and II. for the smaller local works plant, because in the supply stations the plant has been built to careful specifications, is under expert supervision, and there is a reasonable proportion of stand-by plant with consequent relief in the running hours per unit of plant. The 10 per cent. allows depreciation of 5 per cent., and interest is at 5 per cent. (which manufacturers generally assume). Table XII. gives

the real cost of production of the Newcastle-upon-Tyne Electric Supply Co., based on the 1907 figures. Side by side is the power scale of charges based on 1·66 diversity factor. This company has an expenditure of £59.6 per kilowatt installed, of which the cost of the stations has been about £33 per kilowatt: mains and sub-stations, &c., £26. It is interesting to note that the plant installed in sub-stations amounts to about 35,000 kw., supplied by generating plant installed at the station with a

Digitized by Google

total capacity of 20,000 kw. Now it cannot be said that even this company having so large a capital expenditure involved, and operating on such a big scale, is entirely satisfactory in its finances with a depreciation and reserve account amounting to only 1·07 per cent. for the year. The question arises on such an undertaking whether undue expenditure has not been made upon the transmission system.

The author read a Paper in 1904 which dealt with the question of transmission distances in this country, and then showed that at a pressure of 10,000 volts the economical distance for transmitting a load of 1,500 kw. was only 11 miles, where the displaced local station cost £20 per kilowatt. A new diagram (Fig. 1) is now given which shows the effective radii of distribution for

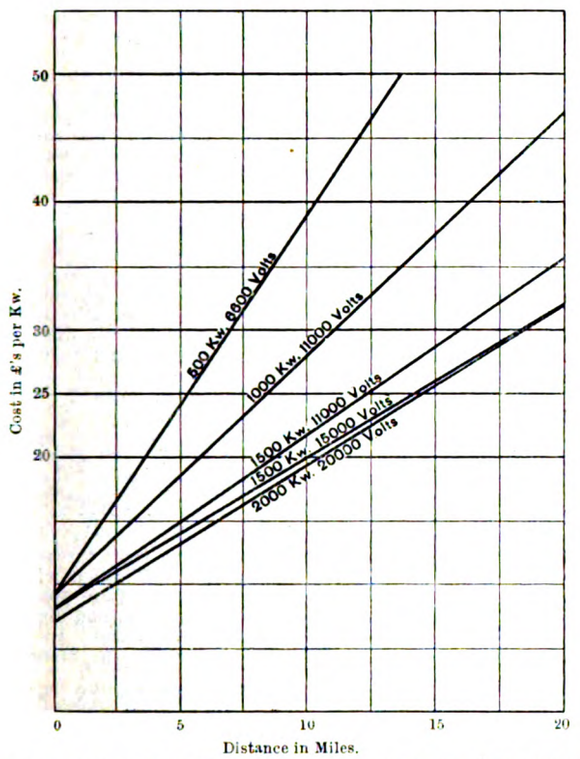

FIG. 1.—COMPARATIVE COSTS OF LOCAL GENERATING STATIONS AND POWER HOUSE, TRANSMISSION SYSTEM WITH SUB-STATIONS.

different loads, and different costs per kilowatt. It has been assumed that every 100 kw. installed at the power station will supply 166 kw. outside; and the cost of the power station is taken at £12 per kilowatt, or £7·2 per effective kilowatt supplied. Each curve represents a consumer, or group of consumers situated at the respective distances and supplied through high-tension cables laid in duplicate and static transformer sub-stations. The horizontal lines show the costs of alternative local stations per kilowatt. The point at which the two curves cross is that at which both systems are equal in cost. It shows, therefore, that so far as capital is concerned the effective radii of transmission in miles are as in Table XIII. These distances, of course, only refer to a comparison between a supply from a central source and local plants installed within factories which usually cost from £20 to £25 per kilowatt. Transmission by

overhead lines would still further increase these radii, of course, but there is still much difficulty and great expense in obtaining the necessary easements for high-tension lines in this country.

Table XIV. sets out the estimated charges of various power companies. In the first column are given the estimated charges which were proposed in the London County Council (1907) Bill, for supply to authorised distributors, column I*a*. being for extra-high-tension untransformed energy at the consumer's terminals, column I*b*. for transformed alternating current at any pressure, and column I*c*. for transformed and converted direct current at any pressure. In the next column are set forth the maximum prices chargeable to individual power users under this Bill; in column III. the maximum price proposed by the Administrative Company of 1906; and in column IV. the real tariff which could be charged by the Newcastle Power Company, based on their 1907 results and with an estimated diversity factor of 1·66, is set out again for convenience.

TABLE XIV.

Estimated Charges from Bulk Supply Undertakings.

Annual Load Factor.	I. London County Council, 1907. Estimated Charges to Authorised Distributors.			II. London County Council, 1907. Maximum Prices to Individual Power Users.		III. Administrative Co., 1906. Maximum Prices.	IV. Newcastle Real Cost based on 1907 Figures and 1·66 D.F.

If Table XIV. is compared with Tables I. and II. it will be seen that a power company can compete successfully with any of these other prime-movers if the power company supply transformed alternating current, but if the power company is constrained to supply direct current, then it is only with smaller plants—*i.e.*, 100 h.p. or less—with which it can hold its own. It is not suggested that the figures in this table are the ultimate minimum charges for power which power companies can afford to make, but they cannot be reduced materially.

The influence of additional capital cost per kilowatt is shown in Fig. 2, in which successive curves are shown adding to each

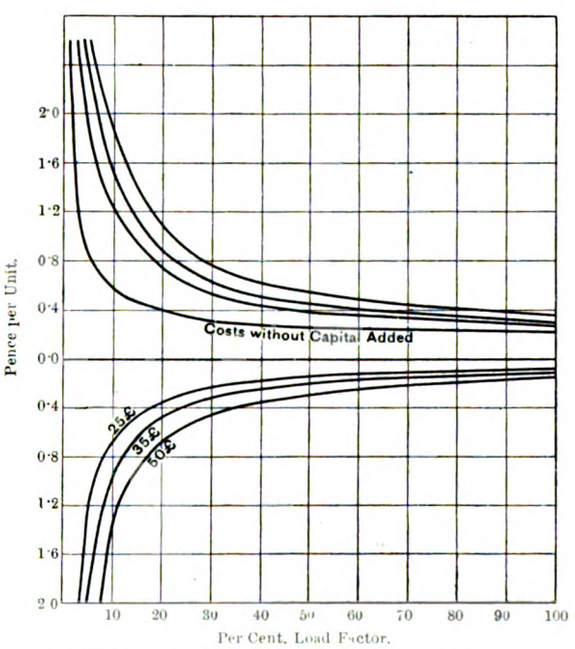

FIG. 2.—EFFECT OF CAPITAL UPON TOTAL COSTS OF PRODUCTION.

	20 %	25 %	30 % L. F.
£50 per Kw.	1·06d.	0·88d.	0·76d.

£25 ,, ...	0·72d.	0·60d.	0·54d.

the capital charges due to the increased expenditure. It will be seen that the difference in cost of production, at 20 and 25 per cent. load factors, between a system costing £25 per kilowatt and one costing £50 per kilowatt, is 32 per cent.—and

Digitized by Google

at 30 per cent. load factor, 29 per cent. This demonstrates very clearly how important it is to minimise the capital involved.

The author believes he has made out a case for showing that in all the larger power stations where the capital expenditure is reduced to a minimum and the supply is produced on a sufficiently large scale but within a reasonable distributing radius, a sound scale of charges for power can be made which can hold its own with any independent local power plant, whether supplied from steam, oil, or gas. The London companies and municipalities, having been the pioneers of supply, are unfortunately crippled by a large expenditure, and, except in a few isolated cases, cannot in the author's opinion so reduce their cost per kilowatt nor increase their production as to meet economically this demand for low-priced power. This problem in London can only be dealt with by centralisation, and all further expenditure on existing individual systems is prolonging an evil which must ultimately be reflected upon the undertakers, and is, in fact, already so doing.

In the provinces many of the smaller boroughs cannot hope to attain such dimensions, and many of them are already saddled with a high capital expenditure per kilowatt, such as to prevent them from offering the low scale needed. This remark does not apply to those smaller boroughs in which power supply cannot become a dominating part of the output, for in such cases among smaller users a larger diversity factor exists, and it may be expedient to sacrifice the principle of a uniform tariff to all classes by offering a special rate to such sparse power consumers. But if this principle—or rather want of principle—be applied in a small industrial town where the power supply may become quite the dominating output, then such a policy can only produce disaster. In such a case there appears to the author to be only one alternative, viz., that all extensions of the local generating plant should be stopped, and that supply should be taken from a power company, if there be one reliably constituted in the neighbourhood, as has been arranged by the Middlesbrough and Tynemouth municipalities, for instance; or a joint Board of local towns could co-operate at a very considerable saving to the respective partners if sufficiently proximate to one another. If this be too Utopian, then possibly the County Council of the district could take the matter up, or by the aid of legislation the principal borough of the group could undertake this responsibility. It would have been much wiser if the controlling authorities— viz., the Local Government Board and the Board of Trade—had prevented some of the smaller local boroughs from adopting their separate electricity stations.

DISCUSSION IN LONDON.

Mr. J. H. RIDER (Chief Electrical Engineer, London County Council), in opening the discussion, said that the importance of the Paper could be judged to some extent by the large number of station engineers who were present thirsting for Mr. Snell's blood. He himself was rising to support what Mr. Snell had said. He was afraid it was rather a common habit for lighting stations with a poor load-factor to try and encourage the power-load by offering a very low price. The attempt was then made to make up whatever loss might accrue from the cheap power supply by charging a higher price than should be charged under the circumstances for private lighting, and more commonly for street lighting, particularly when the station belonged to the municipality which was its own street lighting authority, and could charge practically what it liked for street lighting. They had all heard the story of the fair proprietor who, to induce people to come into the showyard, charged a very low price for the swings, but made up what he lost on them by the profit on the roundabouts. But if the demand for swings was going to become preponderatingly great, then the roundabouts would not make up the loss. Some interesting figures were given in Table VIA. with regard to diversity factor, which Mr. Snell had found in certain classes of works. Mr. Snell also gave it from his experience at Sunderland that he had there a diversity factor of 1·25. He presumed the author was in this case speaking of sub-stations which were supplying lighting and power. It might be of interest to the meeting to know that even with such a constant character load as the London County Council tramways they had a diversity factor of 1·25 among the various sub-stations. He personally was very much surprised at that, considering the fact that the tramway load increased fairly generally over all parts of the system at the same time. Consequently, if they could get a lighting load *plus* a street lighting load *plus* a power load, he thought the figure which Mr. Snell gave of 1·66 might even be too low, which would be all the better for giving a cheap supply. The author had quite properly emphasised the greater expense of using rotary sub-stations as against static transformers. He had been through these figures (Table V.) and checked them, and could corroborate the relative prices of static transformers and rotaries. All those who were trying to sell power cheaply should go in, as far as possible, for alternating current motors, the only disadvantage of which, in certain cases, might be the difficulty of getting variable speed. It was very interesting in Table XIV. to compare Columns I.c. and IV., which gave in the first case the estimated average charges for low-tension direct-current in the L.C.C. Bill, and in the last column, the actual cost according to Mr. Snell, of the Newcastle Company's working. It would be found that all through, from 10 per cent. to 80 per cent. load-factor, the prices were remarkably close to one another. This showed, at any rate, that the character of the curve adopted by the London County Council engineers was a true one. He thoroughly agreed with Mr. Snell's statement that the true way of getting at a scale of charges was to fix the maximum prices on a unity diversity factor. They would then be safe whatever the character of the load. They could then charge an actual price according to the diversity of the various classes of consumers. He also agreed with the author's remark near the end of the Paper that the problem in London can only be dealt with by centralisation, and that further capital expenditure on individual systems or local power houses was wrong.

Mr. A. M. TAYLOR (Birmingham Electric Supply Department) said it appeared to him that the Paper dealt only with the large consumer, and all questions of supplying smaller consumers had been totally ignored. It would not help those who had to deal with the supply to both large and small consumers as was the case in many provincial towns where there were many consumers under 100 h.p. who had to be supplied off the lighting mains. Table VII. was a little misleading, because he took it that Mr. Snell had first calculated the average charges for power for both small and large users and set them against the probable charge by the power company, which apparently only related to the large consumer; consequently, all the costs of distribution from the sub-centres, which were very serious, were eliminated. Probably £20 per kw. would be a minimum figure for distribution to the small users all over a fair-size area, and that was omitted altogether. In Fig. 1, the author appeared to get £7·2 per kw. at the main station as the ordinate for zero distance by dividing £12, shown earlier in the Paper, by 1·66. This, of course, was very low, and according to the figures Mr. Snell published before the Institution of Civil Engineers four years ago, it was only applicable to stations of the size contemplated by the London County Council. Presumably, he had divided the sum for cables by the diversity factor as well. He had also divided the costs per unit by the diversity factor, and this was why Mr. Snell's tables were wrong right through.

THE PRESIDENT (Col. CROMPTON) said that the author wished him to point out that Mr. Taylor was going on a false premiss.

Mr. SNELL said he took the total standing charges, and divided them by the kilowatts of the true maximum demand. He did not divide the cost per unit to the consumer by the diversity factor.

Mr. TAYLOR asked if the same applied to Table IX., which gave the correct costs for certain towns.

Mr. SNELL: I take them in precisely the same way.

Mr. TAYLOR, continuing, said that Mr. Snell passed over the question of storage and sub-stations rather briefly, but four years ago he had recommended it rather strongly. He believed there was really a future for storage at sub-stations, especially in connection with long distance lines. He believed it would be possible by this means to double, if not treble, the length of line to which Mr. Snell said it was possible to extend supply.

Mr. A. H. SEABROOK (Chief Electrical Engineer, West Ham Corporation) said there were one or two things he could not reconcile in the Paper. In Tables I. and II., the average costs in the last column appeared to him too low. Even allowing for the difference of cost of fuel in the North of England and in the South, the result given was entirely contrary to his experience. But even supposing they were correct, he did not see what any power company was going to do in the way of taking them over, because if they took Table II. for a load factor of 25 per cent., the average costs were 0·615d., and there was not much margin between that and the figure of 0·679d given in Table XIV., sub-column *b*. He thought there was something wrong there. If a big station with 12,000 kw. or 15,000 kw. units could not get a bigger margin than 0·02d. per unit, there was surely some explanation for it. The details of individual tests also did not support the figures in Tables I. and II., and were contrary to his experience, correcting, of course, for the cost of fuel. Further on in the Paper he found that old friend the £12 per kw. station. He would really like to know whether it was possible to build a station at that figure, or even double that figure. The Newcastle Company had been credited with cutting these things about as fine as possible; but, as the author assumed himself, the cost of their station was £33 per kw. Further, they did not appear to be extending their main Carville station, but were building on another site on the Tyne, so that it was to be assumed that they had found the limit of economical power stations. The cost of sub-stations mentioned by Mr. Snell appeared to him to be rather high. His figure, compared with the cost of a great many recently constructed in West Ham, was quite double, and the same thing applied to rotary sub-stations up to 200 or 300 kw. capacity. With regard to the space taken up by static chambers, 0·8 square feet per kw. seemed very high indeed, because the best place for them was outside the premises altogether, say on the roof, where they could get plenty of ventilation. He

Digitized by Google

had no doubt that other London engineers with greater experience would give their views upon the author's idea as to the solution of the difficulty in London. Personally, he did not believe the large power station was the solution of the problem at all. The problem was quite a different one to that in the provinces, where they sent out half a million to a million units per annum. In London 12 to 20 millions were sent out over a very small area, such as the City of London Company, for instance, with one square mile. Comparing Table VIII., giving the true costs of production from various power stations in the provinces, with Table II., apparently Manchester, Nottingham, Leeds, and Glasgow had a cost of production of double that of a private installation of from one to 500 kw. Newcastle also, in Table XII., showed a considerably higher cost per unit than the same small private installations. The author's warning that the future would bring a very large proportionate increase of low-price power units, while, with improvements in lamps, the proportionate lighting units might fall below their present figure, was unnecessary, for if the charges had been calculated correctly, there would be no reason that a lower average receipt per unit would imply a lower net profit. It was quite obvious that if the power units were incorrectly calculated it would be disastrous, and it would be specially so in his (the speaker's) station, where four-fifths to five-sixths of the main output consisted of the low-price units. But he was convinced that the cost at which they had put these power units was correct. He admitted that his present balance sheet was not very brilliant, but this was due to other causes—not to the reduction to power consumers, but mainly due to reductions to lighting consumers. In Table XIV., main column 1, there appeared to be a bigger difference between the sub-columns than there ought to be. He could not reconcile, for instance, at a 25 per cent. load factor, that the untransformed extra high-tension price of 0·508d. was changed to 0·583d. transformed. The very high efficiency of modern transforming plant and the small capital cost surely could not mean such a difference as that. Again, the author stated that "If Table XIV. is compared with Tables I. and II., it will be seen that a power company can compete successfully with any of these other prime movers if the power company supply transformed alternating current; but if the power company is constrained to supply direct current, then it is only the smaller plants, *i.e.*, 100 h.p. or less, with which it can hold its own." Considering that the bulk of the small boroughs and installations consisted of direct current, it did not seem to him that if the power company could only take up to 100 h.p., the small boroughs were going to receive much benefit. He was quite certain the author could explain all these points, but he thought it only right to mention them.

Mr. J. A. JECKELL (Chief Electrical Engineer, Coventry Corporation) said he was very much afraid that if Mr. Snell's figures were correct there was not much chance for many station engineers to induce consumers to take a supply of energy at all. Table IX. showed that with a load factor of 25 per cent., Manchester was bound to charge 0·95d. per unit; Nottingham 1d. (there were perhaps reasons for this), Leeds 0·99d., Glasgow 0·99d., whilst the average came out at 0·99d. He ventured to think that although the consumer who had only about 100 h.p. would be willing to pay these prices, the consumer who wanted 500 h.p. to 5,000 h.p. would certainly not pay that price. He felt sure, therefore, that somehow Mr. Snell had prepared his tables from a wrong basis. He would take an extreme case—namely, Coventry, with which he was connected. Going back to the time when Coventry had only a lighting supply, the cost of production, according to Mr. Snell, came out at about 6d. per unit; what chance was there of anybody inducing any consumer to turn out a steam engine or a gas engine with a charge like that? Fortunately, possibly, he did not prepare his calculations in the same way that Mr. Snell had. The position which he personally took up was that having already a lighting station, he did not propose to charge the power consumer the capital charges which were incurred on the lighting plant at all. Supposing a manufacturer took over premises and he found that £100,000 had been spent in, say, making cycles. Assume these works did not make a profit, and the manufacturer decided to put down by the side of them some buildings, using the same offices, &c., to manufacture motor cars. Against the price that he was going to charge for his motor cars, he would naturally not debit the capital charges on the cycle works, but would only debit against the new undertaking the capital charges incurred on that new undertaking. Then if he made money on the new undertaking, he could, if he liked, depreciate, at any rate he pleased, the plant which perhaps had become to a certain extent obsolete with regard to the cycles. To apply this to the Coventry Electricity Works he said they had, as a matter of fact, spent £75,000 on a lighting station, the cost of production at which was over 6d. per unit. They spent another £75,000 on a new station, and the cost of production there came out at 0·89d. For this supply they obtained about 1½d. per unit, and the result was a balance sheet which showed that the true cost of production came out at 1·63d., which happened to be less than the price obtained for the current. But had they started with the supposition that the power consumer had to be debited with capital charges on the old lighting plant, they then could never have offered to supply power at a price at which the ordinary consumer would take it. However desirable it might be to reduce the capital charges on a station, it was equally necessary to reduce the manufacturing or station charges. He thought it would be found that if they expended £10 per kilowatt more on a station and had a load factor of 22½ per cent. (this was a convenient one simply because they sold 2,000 units per kilowatt demanded) at 7 per cent. capital charges, the extra cost per unit owing to the 10 per cent. extra capital meant 0·1d. If they would take the Board of Trade returns, it would be found that between stations of somewhat similar size they had in the station costs a difference of 0·3d. or 0·35., which meant that one station could have spent £35 per kilowatt more than the other, and yet the total station charges *plus* capital charges would have come out the same. They had also to remember that they could not reduce capital charges on an existing station unless they could put down another station by the side of it, but they did know that they could start and reduce station costs possibly without a single penny expended. He thought Mr. Snell must really have made a mistake with regard to the cost of static sub-stations. In Table VI. he had put down the cost of sub-stations with a capacity of 100 to 250 kilowatts at £3 3s. per kilowatt. He was sure that they did not spend so much money as that in the North of England; £2 per kilowatt would well cover it. In the outside area which the Coventry Corporation was now authorised to supply, they were proposing to give the supply by means of kiosks with transformers in them. Two 25-kilowatt transformers in a kiosk cost £100, or £2 per kilowatt. There must be some special reason for Mr. Snell's £3 3s.

Mr. W. H. PATCHELL cordially agreed with that part of the Paper in which co-operation was recommended rather than the extension of small stations. That was the creed started in 1905 by the chairman of his old company (the Charing Cross, West End, and City Electricity Supply Co.), Mr. Fladgate, and he thought if that had been loyally worked to by the companies and authorities in London they would probably have settled this power question once and for all in London long ago. On the question of costs, it was evident that in some cases the capital expenditure had been greatly increased by the necessity of giving a supply within the Board of Trade limits of variation of pressure. He lately heard this question put in all seriousness: What lamps had I best use when my pressure varies from 90 to 115 volts? That was not put by a London engineer, although it might be a case of *proxime accessit*. There the metallic filament lamps scored. A good many of the power company mains which now give an indifferent supply for carbon filament lamps would give a very good supply for metallic filament lamps, and the regulations of the Board of Trade might be modified, with advantage to the power companies, to suit metallic filaments. With regard to the small stations which Mr. Snell had tabulated, he did not quite see how they could fairly look at the cost of a station on the same basis, whether it was for 1 h.p. to 100 h.p., or from 100 h.p. up to 500 h.p., because the cost of labour affected the question so very largely. Mr. Snell, after spending all this time on the arithmetic, afterwards stated, "There is no proportionate charge for supervision or general establishment charges, or for rating." Really, that discounted the value of those figures very materially. Neither did he see the use of averaging the cost of steam, oil, and gas in the Tables I. and II. Nobody ran a three-line engine, one steam, one oil, and one gas. If that last column of Tables I. and II. had been filled by a statement on a power company basis for comparison, such as £6 per kw. and a farthing per unit, it would have been seen how the power company load factor affected the cost. It was very unfair, he thought, to speak in the same breath of the cost of a private plant which only ran economically 54 hours a week, with the cost of supply from a station which worked 24 hours a day. There had been a good deal of fallacy on that ground, and the poor man who was offered a gas engine plant never dreamed that the cheap supply would only be for eight or nine hours a day, and that there were considerable extra charges if they had to run overtime. So that really the equivalent hours were misleading unless they knew the basis—whether it was long hours and average load, or shorter hours and high load. Referring to Mr. Snell's reference to paper mills, Mr. Patchell said that it was sometimes misleading to take the figures given by paper-mill people, who used a very large quantity of their steam for boiling and a very small proportion for power. If they wished to tempt a hotel manager to shut down his private plant, they had to remember that his kitchen cost nothing whatever to run, as his engines supplied exhaust steam for heating; if he shut down his electrical plant and got his supply from the company he began to realise what his kitchen really cost him. A good deal of the disappointment the power companies had experienced had been due to the ridiculously small amount of energy which was taken to run some works. When the power Bills were first thought of in London, the horse-power of boilers was converted into horse-power in machines, and that was gravely used as the basis of the horse-power available for electrical driving in London. But some works took ridiculously small figures. He had some figures of a wagon shop, which was turning out 500 wagons a year. There were seven motors in that shop, of an aggregate of 150 h.p., and the units used per month per horse-power installed were only 17. In a brewery with 16 motors, the aggregate power

Digitized by Google

of the motors was 167 h.p., and the units used per month per horse-power were 28. In a colliery he had nine motors aggregating 1,060 h.p.—60 h.p. of which was in two 30-h.p. pumps—and even allowing for that the units used per month per horse-power were only 36. Another case which would make the mouths of London engineers water was an 85-h.p. motor driving a fan which took 580 units per horse-power per month; but in the manufacturing trade the units used for driving the works were surprisingly small. In this connection it might be useful to members who wished to follow the question further to refer to a Paper by E. W. Lloyd, which was really a report to the National Electric Light Association on the purchase of electrical power in factories. It was published by the National Electric Light Associations Convention in June, 1905.

The discussion was then adjourned, and will be continued this evening, not at the usual place, but at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, S.W.

DISCUSSION IN DUBLIN.

The Paper was discussed simultaneously in Dublin last Thursday.

The CHAIRMAN (Mr. T. TOMLINSON), in opening the discussion, complimented the author on the fairness of the statements in the Paper; he had pointed out clearly both the possibilities and limitations of centralised power production and distribution. Mr. Tomlinson then showed curves that he had plotted for Tables VIII., X., and XII. He regretted that the author had not given information as a basis upon which these tables had been prepared, and hoped that the author, in his reply, would give that information, and also define his definition of load factor as he had used it. The speaker then gave a series of figures he had himself worked out in connection with the Dublin and Central Ireland Power Company, of which he was engineer. He assumed a generating station of 5,000-kw. capacity, consisting of five 1,000-kw. units, one of which would be a spare. He then took two cases of supply—one close by the power station, the other 27 miles away. The earning capacity of such a plant was 4,000 kw. The capital cost for a gas plant was £17·5 per kilowatt installed. Therefore the capital cost per kilowatt of earning capacity, £22; to this must be added £4 for transformers and switch gear, and £5 for Parliamentary and establishment charges, a total of £31 per earning kilowatt. The cost of a duplicate overhead line was £6·5 per kilowatt, assuming the pressure to be 30,000 volts. The cost of operation, excluding fuel and distribution, would be £6,600, or £1·65 per kilowatt, and distribution £0·26 per kilowatt. Assuming it was required to earn 10 per cent. on the capital outlay, the earning power per kilowatt must be :—

Interest on capital = 10 per cent. on £31 ...	744d.
Operating expenses = £1·65	396d.
	1,140d.,
Or, allowing 10 per cent. loss	1,266d.

At a load factor of 100 per cent., the cost per unit would be :—

$\frac{1266\,d}{8760} = 0{\cdot}145d.$, to which cost of fuel must be added.

Assuming the diversity factor to be unity, then the cost per unit would be 1,266 = hours' demand × price per unit.

Similarly, in the case of a long transmission, the earning power would be :—

Interest on capital = 10 per cent. on £37·5	= 900d.
Operating expenses	£1·65 = 396d.
Distribution charges	£0·16 = 62d.
	1,358d.,
or, allowing 2 per cent. loss in distribution,	1,698d.

The cost per unit at 100 per cent. load factor would again be :—

$\frac{1698}{8760} = 0{\cdot}194$ pence *plus* cost of fuel. For any other load factor the cost per unit (less cost of fuel) is then given in the following table :—

Annual Load Factor per cent.	Distribution near Generating Station.	Distribution 27 miles from Generating Station.
	d.	d.
10 ...	1·444 ...	1·940
20 ...	0.731 ...	0·970
30 ...	0·486 ...	0.646
40 ...	0·364 ...	0·484
50 ...	0.291 ...	0·390
60 ...	0·243 ...	0.323
70 ...	0·208 ...	0·226
80 ...	0·182 ...	0.242
90 ...	0·162 ...	0·215
100 ...	0.144 ...	0·194

In the scheme for which these figures were prepared, the speaker added, no addition need be made for fuel costs, as the plant was intended to be driven from producer gas obtained from peat fuel, and it was estimated that the recovery of the sulphate of ammonia would at least cover the cost of peat used. The "diversity factor," where operative at the lower load factors, would reduce the cost per unit.

Mr. MARK RUDDLE (Engineer-in-Chief, Dublin Corporation Electricity Works) said it was all very well for Mr. Snell to criticise the heavy capital outlay per kilowatt in some of the older stations, but it was there, and the difficulty had to be faced. Mr. Snell appeared to consider that only in a big power company could there be salvation. Mr. Ruddle, however, thought it was easy to work out a very rosy result for a hypothetical power company, but in practice the business had to be got, and the best plans frequently had to be departed from. For instance, primarily one might schedule a certain street or district as good for power requirements, but later, when the undertaking came into operation it was often found that the demand was in quite another quarter, which necessitated deviation from the original plans, or perhaps a duplicate expenditure. The speaker did not share Mr. Snell's pessimistic attitude towards those companies and corporations who were supplying power at low rates. In many cases the power load had resulted in a great reduction in costs, and he considered that there was every hope for the existing systems. In any case it was altogether too early to condemn them. The whole Paper was apparently considered from the view of the necessities of London, but personally he was not at all sure that it was not a sounder policy to divide the risks among a number of stations rather than concentrate the whole. Mr. Ruddle considered that a 5,000-kw. station could be just as economically worked as a 25-kw. one. Finally, he asked the author how he had determined what he had termed the "correct charges" which the London companies and authorities should make as given in Table VII.

Mr. L. J. KETTLE expressed the opinion that if Mr. Snell's figures were correct nobody would buy electrical energy, whereas the Dublin Corporation were doing a considerable and growing business in supply for motive power. He was very interested to notice that according to Mr. Snell's figures suction gas plants cost more to run than steam; he had always understood that the reverse was the case, at any rate so far as small plants were concerned.

Mr. P. S. SHEARDOWN (Electrical Engineer, Dublin United Tramways) said that the capital cost per kilowatt of the largest power company, that at Newcastle, was £59·6, and in the light of that the figure of £12 given by the author seemed absurd.

Proposed New West Indian Cable.—At a meeting of the executive committee of the West India Committee on Thursday, Sir Nevile Lubbock presiding, a resolution was passed favouring the establishment of an all-British cable to the West Indian colonies via Canada.

Heavy Electric Cars at the Berlin Automobile Exhibition.—Electrically-propelled vans and other heavy vehicles formed quite a prominent feature of the recent Automobile Exhibition at Berlin, and showed clearly that much more attention is being paid on the Continent, as is also being done in America to this class of vehicle. One of the most interesting of the exhibits of this nature, a *résumé* of which is given in *Motor Traction*, was the series of cars ranging in size up to brewers' drays for two tons, shown by the Bergmann Co., and equipped with the much-talked-of but rarely seen Edison battery in the 175 ampere-hour size. Another prominent exhibit was a large fire escape, shown by the Deutsche-Mercédès-Verkaufs-Ges, mounted on an electrically-propelled chassis, driven by hub motors similar to those familiar in this country on the Mercédès electric carriages (see ELECTRICAL ENGINEERING, Vol. II., pp. 797). The Norddeutsche Automobil und Motoren A.G., of Bremen, exhibited a number of vehicles on the well-known Kriéger system, including a 30 h.p. petrol-electric chassis. A representative collection of vehicles illustrated the Scheele system, which was fully described in ELECTRICAL ENGINEERING, Vol. I., p. 689. The well-known accumulator firm of Hagen showed a number of electric vehicles ranging from a large combined fire engine and escape for Düsseldorf and a large street-washing machine. The Siemens-Schuckert Co., who, we believe, have only recently taken up this class of work, showed nine vehicles. Like a number of the German firms, this company believe in the hub motor for some purposes, but exhibit other types as well. Perhaps the most notable feature of these cars is the arrangement of the switchgear. Great care has been taken to obtain very graduated variations from one "speed" to another, and a field rheostat with an exceptionally large number of contacts is employed. The gearing between the controller handle and the switch appears unnecessarily complicated. The application of either brake cuts off the current, but to start again it is necessary to bring back the controller to zero. The majority of the exhibits except two or three notable examples appear to be somewhat in the experimental stage, and a tendency to employ somewhat undersized batteries is apparent.

A NEW PETROL-ELECTRIC OMNIBUS FOR PUBLIC SERVICE

ON more than one occasion we have remarked upon the shortcomings of the usual mechanical gearing and clutch mechanism of the ordinary petrol motor omnibus, as we know it in the streets of London, under the exceptionally severe conditions which it is called upon to fulfil, and have drawn attention to attempts that have been made to introduce an electrical form of transmission gear, with the object of obtaining greater smoothness of action, freedom from noise, and diminished cost of upkeep. (ELECTRICAL ENGINEERING, Vol. I., pages 456, 461, and 463.) Quite a considerable number of such systems, varying a good deal among themselves, have been brought forward, companies have been floated, and more or less extensive trials have been made with the object of detecting the weak points in designs which had appeared feasible on paper. It is of some interest, therefore, to learn that after all this preliminary work an actual petrol electric omnibus is now being put to the test of regular work in London by Messrs. Thomas Tilling & Co., Ltd., and started running on the Sidcup and Oxford Street route on Saturday.

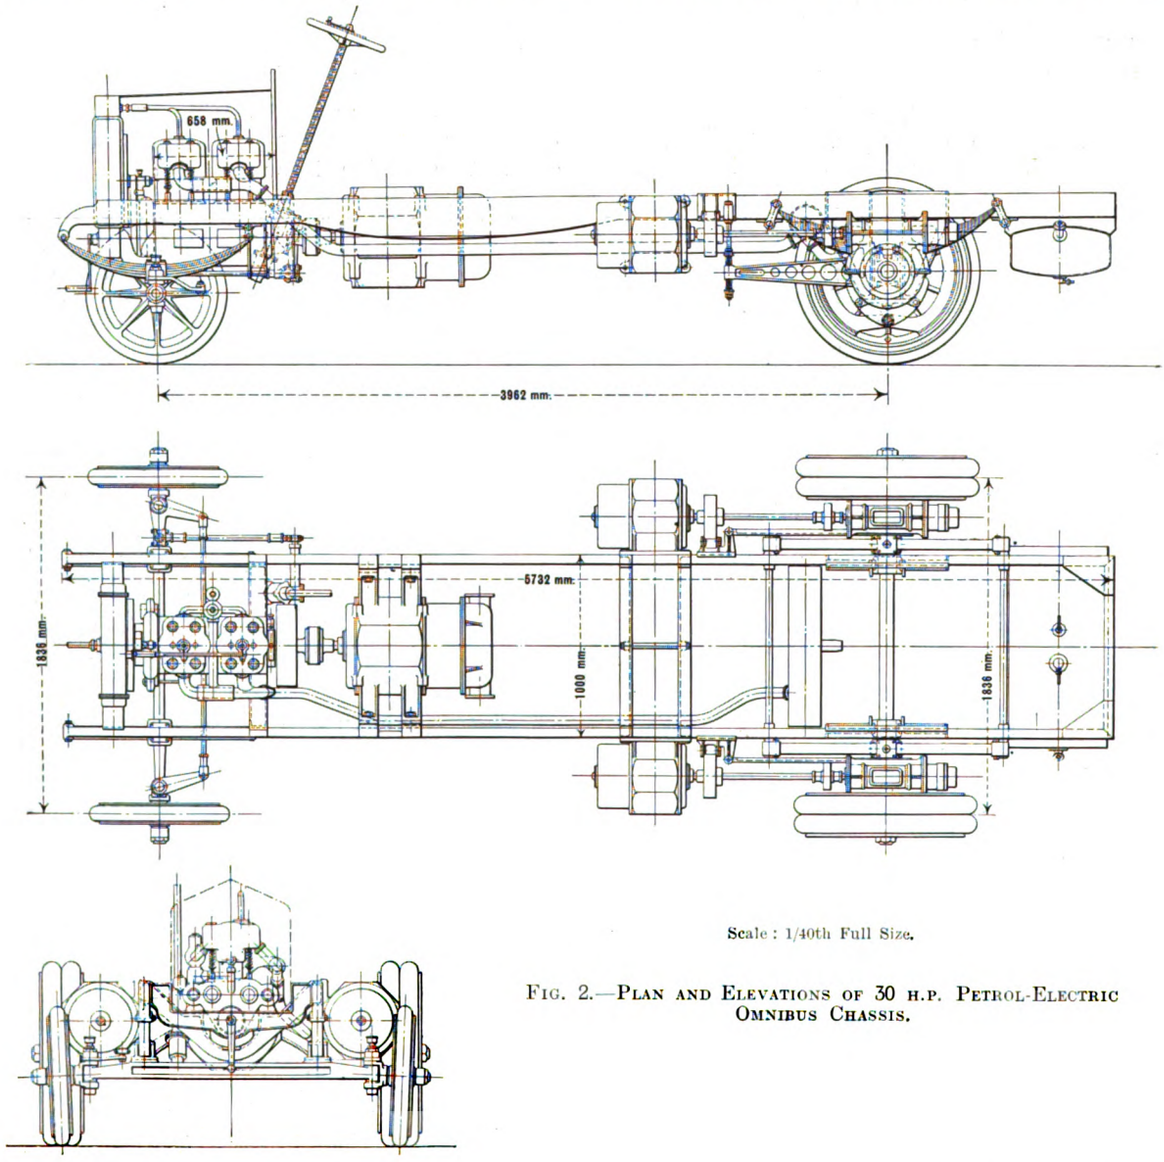
FIG. 1.—"HALLFORD" PETROL-ELECTRIC OMNIBUS.

The chassis of the omnibus in question, which is fitted with one of Messrs. Tilling's standard 34-seated bodies, was supplied by Messrs. J. & E. Hall, Ltd., of Dartford, by whom the engine, frame, and all mechanical parts were constructed, and is fitted with an electrical equipment manufactured by Messrs. W. A. Stevens, Ltd., of Maidstone. In numerous details, the design has benefited by the experience of the actual conditions of motor omnibus work of Mr. P. H. Frost Smith, chief engineer to Messrs. Tilling's motor department. The complete omnibus is known as the "Hallford," and the petrol-electric system is covered by the "S. B. & S." syndicate and Stevens' patents. A view of the vehicle is given in Fig. 1, and full details of the arrangement of the chassis can be seen in Fig. 2.

The engine is similar to that employed in the Hallford heavy vans, which received one of the gold medals in the recent commercial vehicle reliability trials of the Royal Automobile Club, and is of the four-cylinder vertical type, with an R.A.C. rating of 30 b.h.p. The cylinders, which are each of 110 mm. bore × 140 mm. stroke, are cast in pairs, and a symmetrical arrangement of the inlet and exhaust valves on opposite sides of the engine, and actuated by separate cam shafts within the crank chamber, is adopted. High-tension magneto ignition is employed, with duplicate plugs for each cylinder, and forced lubrication is used throughout. A throttle governor is provided, which can be set for speeds up to 1,050 r.p.m. This is the maximum speed at which the engine can be run under any circumstances. Ball bearings are employed for the main crankshaft, but not for the connecting rod big ends. The engine is supported on two steel cross frames at three points only, thus allowing a considerable degree of flexibility.

Before proceeding to describe the electrical equipment and method of driving the road wheels, attention may be drawn to the design of the steering-gear and front axle. A straight solid forged steel axle is employed, the central part of which is of girder section with a tapering portion at each end, and the steering gear, which is remarkably simple, is arranged so that all its working parts are well protected by being above and behind the axle.

The electrical equipment, like that in the earlier forms of Messrs. Stevens' system as applied to smaller vehicles, is of the type where the transmission is at all times electrical, without any mechanical connection between the engine and the road wheels, and works with continuous current without employing accumulators. It simply takes the place of the clutch and gear-box of the ordinary mechanical system. As will be seen, however, the arrangement of control is somewhat different from that of the petrol-electric equip-



Digitized by Google

ment which Messrs. Stevens showed at the Commercial Vehicle Exhibition at Olympia last March (see ELECTRICAL ENGINEERING, Vol. I., p. 462), in that two motors are employed, and the generator has not a double-wound armature. The solenoid control of the engine throttle has also been abandoned. The general feature aimed at has evidently been simplicity, which is all important in this class of work.

The dynamo, which can be seen in position in Figs. 3 and 4, is connected to the flywheel of the engine by means of a flexible coupling. It is of the enclosed type, with cast steel frame and aluminium end plates, and weighs complete about 8 cwt. It will be noticed in Fig. 4 that it is supported from lugs attached to the frame by brackets cast on to the case. The suspension is so arranged that by withdrawing a few bolts and sliding the dynamo a few inches longitudinally, it can be lowered and removed from below without disturbing any other part of the mechaism.

Although enclosed, the dynamo is most efficiently ventilated by a Sirocco fan, mounted on the back end of the armature shaft inside the casing, which draws air right through the machine from an intake aperture at the top, covered with wire gauze. The generator is of the four-pole, shunt-wound type, provided with interpoles, and is designed for an output of 200 amperes at a normal voltage of 180 volts. It can, however, work up to about 200 volts. The utmost care has been taken in the proportions of the winding of the interpoles, with the result that not only does the machine run sparklessly under the trying conditions of varying load and voltage to which it is subjected, but, as has been shown by repeated experiment, the armature can be absolutely short circuited practically without sparking. "Morganite" brushes are used on both dynamo and motors.

The position of the motors is shown clearly in Figs. 1 to 4. They are mounted rigidly in a longitudinal position outside the frame, and each drives one of the rear road wheels through a telescopic universal joint, a short cardan shaft, and thence through universal joints of the ordinary star pattern, and a specially designed worm gear with a 12 to 1 ratio. There is thus an entire absence of spur or bevel wheels and chains, and as each motor drives its own wheel, the differential gear is entirely eliminated. The design of the back axle is particularly worthy of note. A "dead" axle of solid steel is employed, provided with horn blocks, the bearings of which are spherical and therefore capable of movement in every direction. The arrangement of the worm gear by which the wheels are driven is shown in Fig. 5. The worm casing is bolted to a flange forged solid on the axle itself, on to which flange is secured the torque rod, which is steadied at its outer end by two heavy springs. The worm wheel is carried on a housing supported on ball bearings of ample size, provided with separate ball races for taking the thrust. The connection between the worm wheel and the road

Scale: 1/40th Full Size.

FIG. 2.—PLAN AND ELEVATIONS OF 30 H.P. PETROL-ELECTRIC OMNIBUS CHASSIS.

Digitized by Google

wheel is by means of a dog clutch, so that the wheel can be readily taken off for the renewal of tyres, &c., at any time, without in any way disturbing the worm gearing. This arrangement also obviates any side strain to which the worm wheels might be subjected. The worm itself forms simply a prolongation of the cardan shaft, and is also provided with ball bearings and thrusts. The worm wheel is constructed of phosphor bronze, but the worm is of hardened steel, and the whole runs in a special graphite grease. A water-cooled brake drum is mounted on each motor shaft, close up to the motor, in a most accessible position for inspection and adjustment, and powerful side brakes of the expanding type act upon the inside of the rim of each road wheel. It may be suggested that there is a possible course of danger in the rapidly revolving motor shafts being exposed, but a light removable cover could easily be arranged.

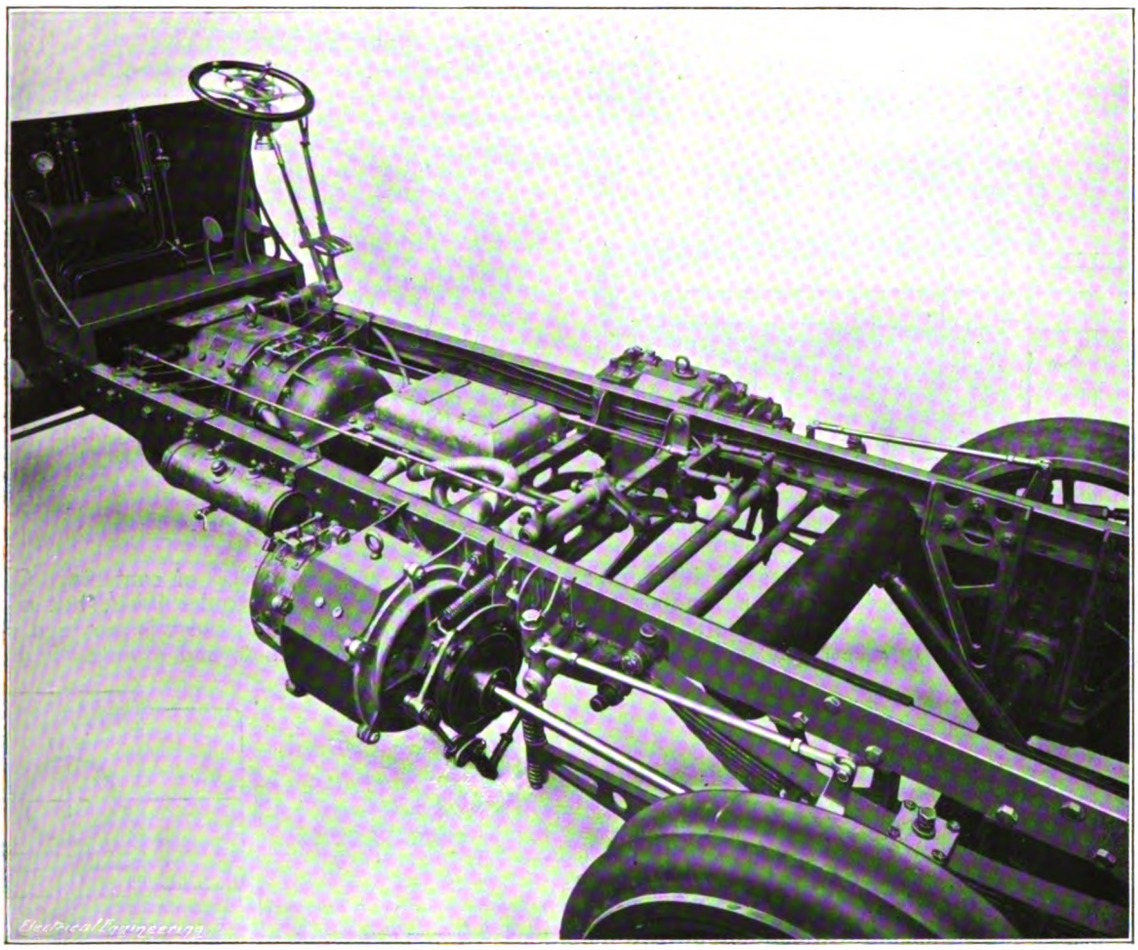


Fig. 3.—View of Chassis, showing Electrical Equipment, &c.

The motors themselves are of the four-pole, series-wound, enclosed type, closely resembling the ordinary tramway motor in the main points of their design. They are of ample size to deal with the whole output of which the generating set is capable, and weigh about 400 lb. each. Control of the vehicle is effected partly electrically and partly by means of the engine throttle. A full diagram of connections is given in Fig. 6. The main items of the control equipment are the main controller, worked by a side lever, which is used to place the motors in series or parallel and for reversing, and the field regulating rheostat of the generator, which is worked by a small lever moving over a quadrant on the steering wheel. There is also a main switch actuated by a pedal. The engine control is effected by a throttle lever on the steering wheel, which works in connection with the engine governor, and can be set to cut the engine down to a low speed, and an accelerator pedal, by which the throttle can be opened irrespectively of the position of the throttle lever, but which if released allows the engine to take up the reduced speed determined by position of the throttle lever.

The main controller corresponds exactly to the ordinary "change speed" lever, giving two forward speeds (series and parallel), and one (series) reverse. No series resistances are used. It might be thought

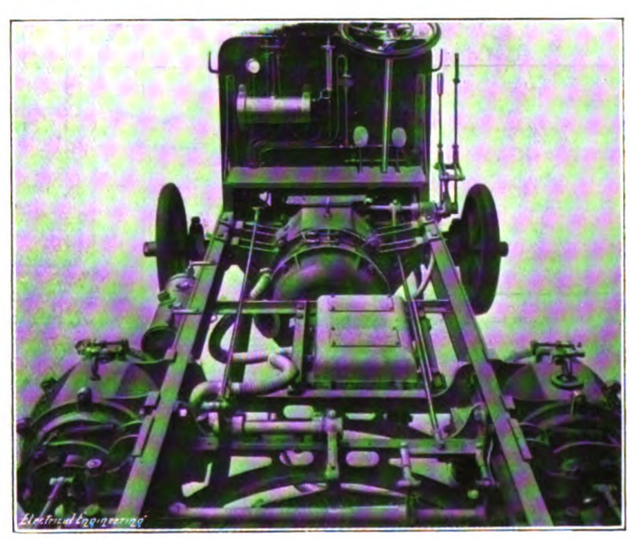

Fig. 4.—View of Chassis looking Forwards, showing Method of Supporting Generator.

Digitized by Google

that only two "speeds" would not be sufficient, and with mechanical gearing this would certainly be so, but the extreme flexibility of the electrical transmission, owing to the voltage control of the dynamo, and the perfect smoothness with which it takes up its work, goes far to eliminate the necessity for a number of steps to the main controller. Although the speed on hills might be improved, in practice it is found that except on very steep hills the controller can be left permanently in the parallel position, upon which all starting and manœuvring in traffic can be done. The main controller itself is contained in a case under the driver's seat, and consists of an inner and an outer ring of metallic contacts on a slate base, arranged as shown in Fig. 6. Over these contacts moves a four-arm switch piece carrying brushes for suitably connecting the inner and outer ring of contacts. Current is never broken on this controller itself, but a separate main switch, referred to already, is provided, which is fitted with carbon contacts and a magnetic blow out. This switch is worked by a pedal, and is interlocked with the controller lever in the manner shown in Fig. 7, so that the lever can only be moved when the main circuit is broken. There is, however, no arrangement

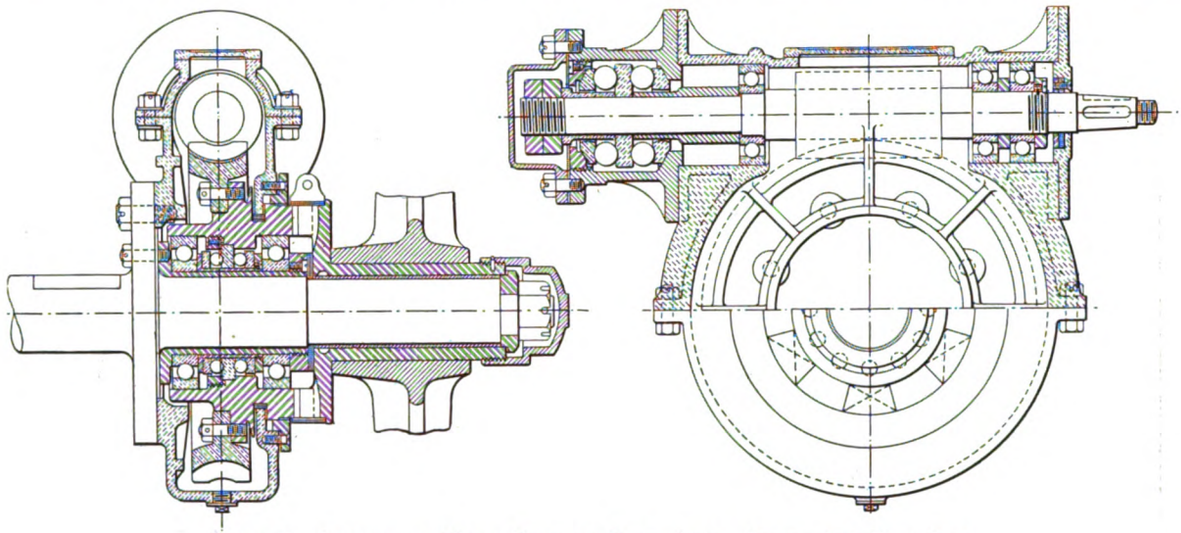

FIG. 5.—SECTION OF WORM GEAR ON BACK AXLE. SCALE: $\frac{1}{8}$TH FULL SIZE.

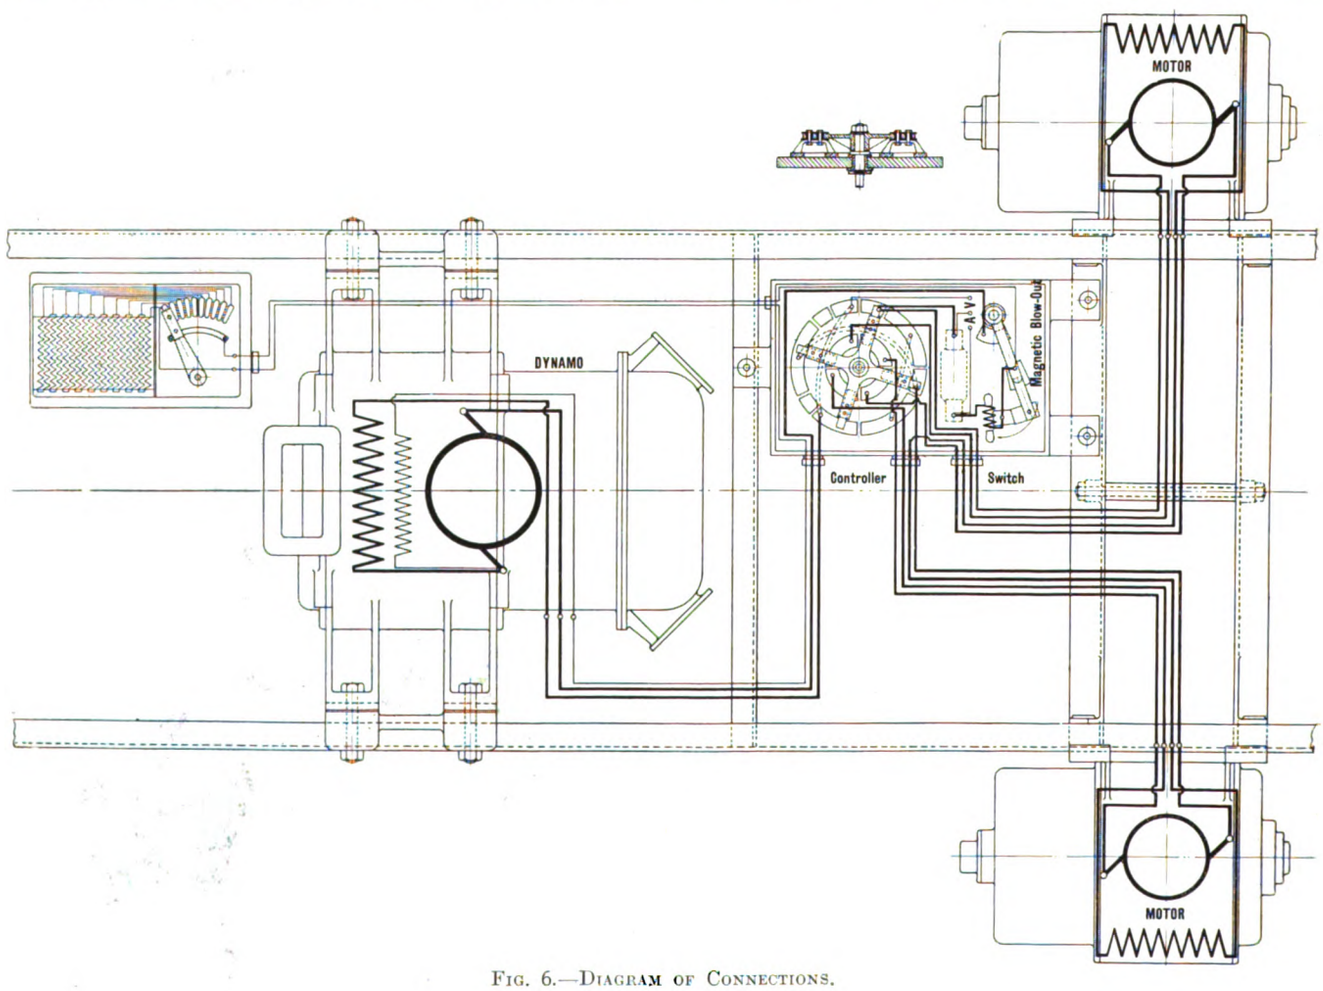

FIG. 6.—DIAGRAM OF CONNECTIONS.

Digitized by Google

for ensuring that the lever is in the neutral position when the engine is started, so that there is a possibility of the vehicle starting off if the lever has been inadvertently left in the forward position with the brakes off. No provision is made for electric braking. The field-regulating resistance for the generator is contained with its switch in a watertight case inside the engine bonnet on the right-hand side of the engine, near the magneto. The wiring from the controller to the generator and motors is enclosed in flexible metallic tubing with watertight screwed joints.

The control of the speed of the vehicle is effected almost entirely on the accelerator pedal and the field switch, and under ordinary conditions the main circuit is never broken, even at stopping. Before starting, unless the gradient is very steep, the controller lever is put into the parallel notch with the engine running slowly, and the generator field reduced. In order to start, the brakes are released, and the engine is accelerated by opening the throttle with the pedal so that the voltage of the dynamo rises, the field switch is gradually moved over to raise the voltages as the vehicle gains speed. The running speed is then controlled by the throttle pedal, and to stop the throttle pedal is released. the dynamo field weakened, and the brake applied.

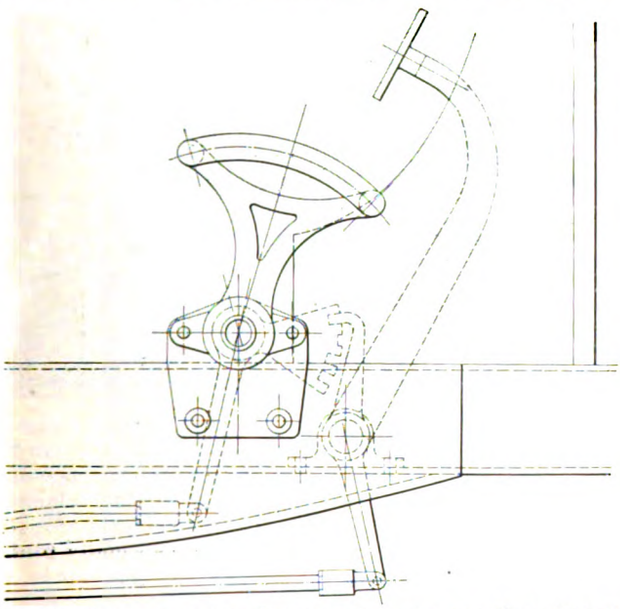

FIG. 7.—ARRANGEMENT OF INTERLOCKING BETWEEN MAIN SWITCH PEDAL AND CONTROLLER LEVER. SCALE: ⅛TH FULL SIZE.

without, however, breaking the main circuit. It should be observed that the accelerator and main switch pedals are both worked by the driver's right foot, and cannot be depressed at once. It is thus impossible for the main circuit to be broken when the engine is running fast. In order to start, the brake has only to be released when the vehicle will gently commence to move. It will be seen that although the principal control is by means of the throttle pedal, attention has also to be paid by the driver to the handling of the field switch. If, for example, the field is too strong during acceleration, when the motors are taking a heavy current, the voltage for a particular engine speed will be too high, and the engine will be overloaded, and will be heard to knock, and in like manner when climbing a steep hill at reduced speed, a reduction of the field is necessary in order to allow the engine to get away with the load. A very small amount of practice will enable the driver to know the best position of the field switch for different circumstances. The manner in which it is handled is not unlike that of the ignition of a petrol engine, which should be retarded when the engine is running slowly heavily loaded to obtain the best results, and advanced for high engine speeds. A short ride on the omnibus soon demonstrates the simplicity of the control and the extreme quietness and smoothness of starting and running. It is intended that the omnibus be driven by a driver who is not allowed to make any mechanical or electrical adjustments, and to prevent interference by unskilled hands the commutator covers of the motors and generator are provided with locks.

The most interesting consideration is, of course, wherein lie the advantages over the ordinary gear-driven omnibus. The increased silence and smoothness of running are obvious, but against them must be put slightly extra weight and possibly a slightly worse average overall efficiency of transmission to the road wheels, which would be unfavourable in hilly districts. On the other hand, it is likely that, owing to the better conditions at starting, a somewhat smaller engine may be used for the same class of service, so that the petrol consumption is not by any means excessive. The main point, however, where economy is to be expected, is in the reduction of garage expenses, and the avoidance of the heavy maintenance and depreciation due to the short life of gears and clutches. Mr. Frost Smith estimates that whereas at present 1·5 men per car are required at the garage in the night shift, 0·75 men per car would be sufficient with petrol-electric vehicles. The following table compares the items of expenditure as ascertained for gear-driven omnibuses with those estimated for the petrol-electric system, taking account only of those headings under which a change is expected.

	Pence per Car-Mile. Gear-Driven.	Petrol-Electric.
Depreciation	1·375	1·000
Running	0·666	0·333
Maintenance	2·500	0·666
Grease, oil, &c.	0·350	0·175
	4·891	2·174

The remaining items would be unaffected. This shows an expected saving of 2·717d. per car-mile.

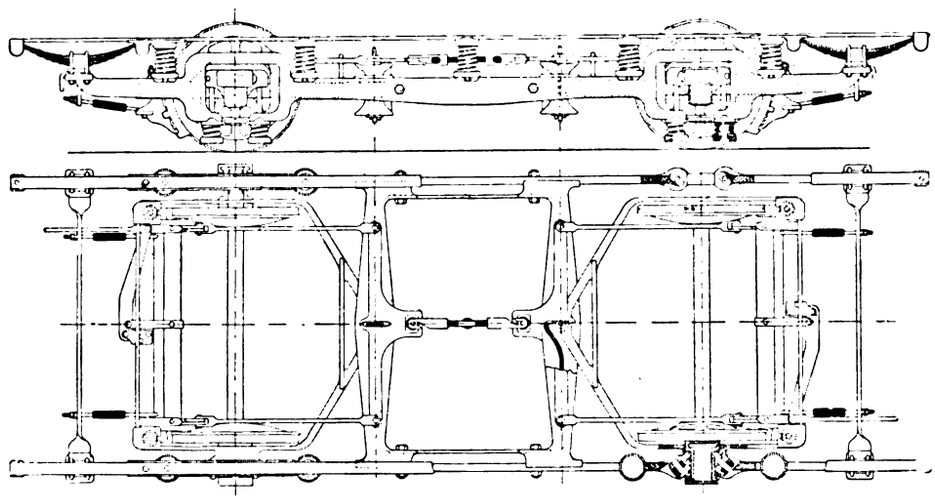
Before the chassis was taken over by Messrs. Tilling's some extensive road trials were made, in one of which a trip was made from London to Hastings, over an exceedingly trying road, with a load representing an omnibus body and half a dozen passengers, when the petrol consumption is reported to have been about eight miles to the gallon.

A demonstration run of the omnibus was held on Thursday last, when, by the invitation of Messrs. J. & E. Hall & Co., a party, which included some representatives of the technical Press, were enabled to form their opinions of the working of the system. A start was made from the Motor Club in Coventry Street at 11.20 a.m.; the route was by way of Westminster Bridge to Peckham, where the first stop was made at Messrs. Tilling's omnibus offices to allow more passengers to be taken up. The run proceeded very satisfactorily to Eltham, where a slight mishap to the circulating pump delayed the run for a few minutes. The journey was soon continued, everything ran smoothly, and the 'bus arrived at Messrs. Hall & Co.'s works at Dartford soon after 2 p.m. The run was accomplished without any electrical troubles, the engine, dynamos, and motors working very smoothly. There was a noteworthy absence of vibration or noise. The 'bus attains a good speed on the level and slight gradients, on which kind of road it was entirely run on with the controller in the parallel position, and only once, when ascending a steep hill just before reaching Crayford, were the motors put in series. On arriving at the works a complete inspection of the vehicle was made, and the commutators of both dynamo and motors were examined. The surfaces of these were found to be in excellent condition, showing a total absence of sparking, and all the armatures were quite cool. The company then partook of lunch at the North Pole Hotel. After lunch the party was conducted round the works and shown many interesting details in the manufactures

Digitized by Google

of the firm. The return journey was commenced soon after 5 p.m., and everything ran perfectly. The route on the homeward journey was through the Blackheath district, and over Shooter's Hill. When about halfway up this hill the motors were put in series. The 'bus was stopped on the steepest part of the hill, in order to see if it would start on that gradient when the motors were in parallel, but after several unsuccessful attempts they were again put into series, and the journey was continued, finally concluding a few minutes after 7 p.m. at the Motor Club.

The 'bus behaved splendidly, and one of the most pleasing features from the passengers' point of view is the easy and smooth manner of starting, absolutely without jerk, but just an easy gliding away. The absence of clutch and gearing entirely does away with the noise and sudden jumps forward which are unfortunately too familiar in the case of the ordinary petrol 'bus. The brakes are exceedingly powerful, but when put into operation the vehicle pulls up with an easy and quiet motion. The system appears well adapted for London and suburban street traffic. The speed on the level is evenly maintained, but on steep gradients the rate of progress is rather slow, although sure.



Starting Large Motor-Generators.—A somewhat unusual method of starting large motor-generators used by the Edison Illuminating Co. at Detroit, is described in *The Engineer*. A pneumatic jack is employed which consists of an air cylinder with a piston connected to an arm, this arm having a pawl engaging a ratchet on the armature shaft. The idea is for this jack to give the armature a single impulse to overcome the standing bearing friction, which is considerably higher than the running friction of any plain bearing, and also to overcome some of the inertia of the rotating parts. It is stated that by the use of this device the machine can be started with a maximum current of 500 or 600 amperes, as against 1,500 amperes when it is started in the usual manner from rest.

Electrical Engineers' Ball.—This annual event is to be held at the Hotel Cecil on Friday, January 31st. Tickets, price one guinea, may be obtained from any of the following members of the Committee:—Messrs. H. Alabaster, A. K. Baylor, J. Horace Bowden, H. W. Bowden, Guy Burney, J. Carlton, T. O. Callender, E. A. Carolan, A. Clift, E. C. De Segundo, R. S. Erskine, A. L. C. Fell, G. Flett, E. J. Fox, T. E. Gatehouse, Sir J. Gavey W. Geipel, Dr. R. T. Glazebrook, James Gray, R. Kaye Gray, A. E. Hadley, Robert Hammond, H. E. Harrison, H. Hirst, J. S. Highfield, H. R. Kempe, J. E. Kingsbury, E. M. Lacey, W. E. Lane, H. M. Leaf, G. C. Lloyd, W. L. Madgen, W. Lee Matthews, W. H. Massey, W. M. Mordey, H. T. S. McKay, P. V. McMahon, F. H. Nalder, W. A. Major O'Meara, G. W. Partridge, J. Petersen, J. S. Raworth, J. H. Rider, Martin F. Roberts, W. Rutherford, J. H. Rosenthal, Alex. Siemens, A. M. Sillar, F. A. Smith, J. Spagnoletti, T. E. P. Stretche, G. Sutton, E. M. Sawtelle, C. P. Sparks, C. D. Taite, J. Taylor, and R. J. Wallis-Jones. The Executive Committee consist of Messrs. J. E. Kingsbury, P. V. McMahon, G. C. Lloyd, Martin F. Roberts, and R. J. Wallis-Jones. Mr. R. Hammond is Hon. Treasurer, and the Hon. Secretaries are Messrs. A. M. Sillar and H. Alabaster.

THE WARNER TRAMCAR STEERING CONTROL

A Flexible Four-wheeled Truck

A LARGE party of engineers, including some representatives of the technical Press, were present on Friday last, at the invitation of Mr. J. Sutherland Warner and the Warner Engineering Co., at a demonstration of the Warner patent "steering control," as applied to tramcars, held, by the courtesy of the chairman, and Mr. H. E. Blain, general manager of the West Ham Corporation tramways. A car fitted with the truck which had been in service on the West Ham tramways for about two years was inspected. Briefly, the idea sought after is the construction of a four-wheeled truck, in which certain degrees of freedom are allowed, which enable the two axles to conform readily to variations in the "straightness" of the track independently of each other, and without causing the body of the car to deviate appreciably from a smooth course. Mr. Warner designates the ideal course of the centre of gravity of the car by the picturesque expression, "The conformity line." A further advantage claimed for his truck against the ordinary parallel axle truck is the diminution of flange and rail wear, especially round curves and on irregular tracks by the avoidance of sudden jerks from side to side.

ELEVATION AND PLAN OF WARNER NON-PARALLEL AXLE TRUCK.

A plan and elevation of the truck is given in the accompanying figure, from which it will be seen that each axle is carried on bearings, which are mounted on a frame pivotted on a king pin between the axle and the centre of the car, while the main frame carrying the body springs is hung by means of short swinging rods from the axle boxes, giving the necessary freedom for angular motion of each axle. The object is in some ways similar to that of the radial axle-box, but is attained in a different way.

The first part of the demonstration consisted in taking a car fitted with the truck a short distance along the road, and tracing a line along the ground by means of a thin stream of whitewash, running from the car body, with the object of showing how little the course of the car deviated from the "conformity line." This test, although sufficient to show what was required, would, of course, have been more striking if carried out on a more irregular track than can be found on the West Ham system. After this the floor boards were taken up in order for the movement of the axles to be watched, and a more extended trip was taken. The so-called steering action was clearly seen, and it was generally agreed that the running of the car was particularly smooth. Finally, a car fitted with an ordinary parallel axle truck was subjected to similar tests for the sake of contrast.

INSTITUTION OF ELECTRICAL ENGINEERS

Election of New President

Photo. by Elliott & Fry.

COL. R. E. B. CROMPTON, C.B.

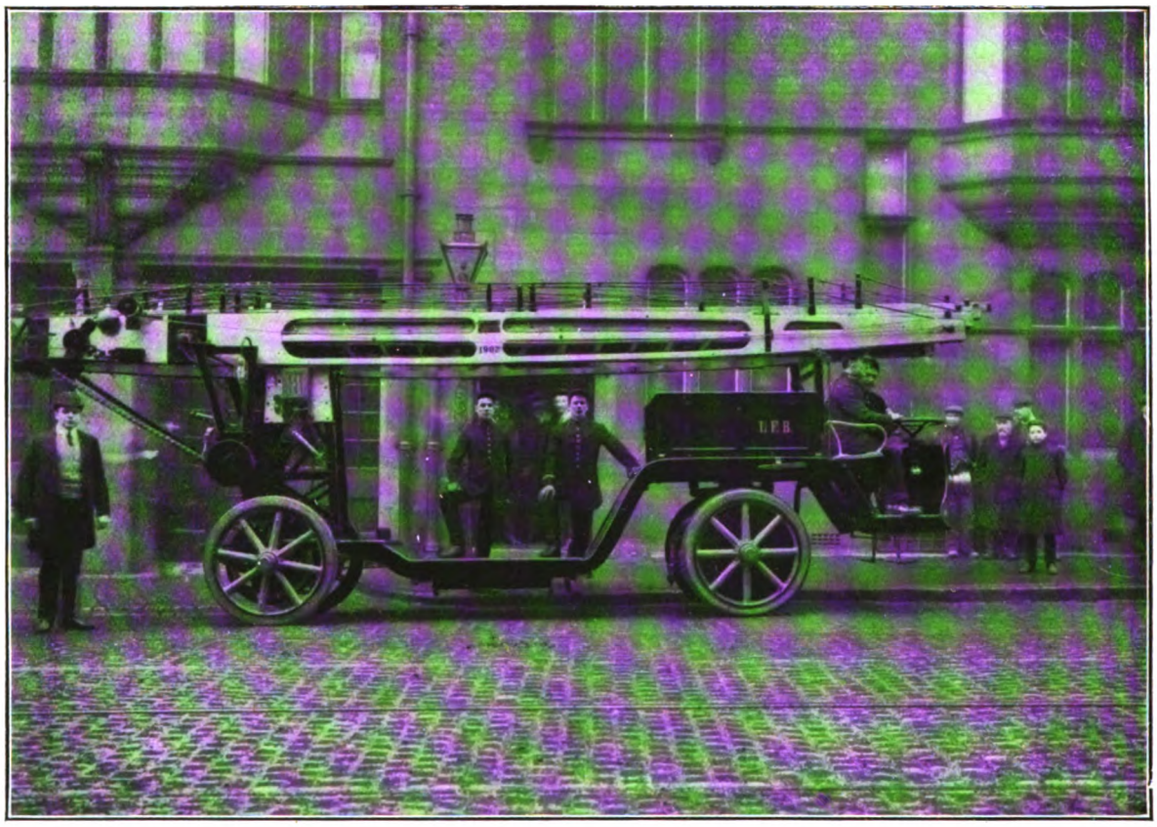
President of the Institution of Electrical Engineers.

AT the meeting of the Institution of Electrical Engineers on Thursday, Mr. C. P. Sparks, the senior Vice-President, announced that at the meeting that afternoon, the Council had unanimously elected their Past President, Col. Crompton, as President for the remainder of the session.

COL. CROMPTON, R.E., who thereupon took the Chair, said it was with very mixed feelings that he came before the meeting. An hour previously nothing was further from his thoughts than that he would have to asume that position. He could not say how deeply he felt the honour of being called upon to succeed the greatest man in the world—at any rate in the electrical world—and how sad it made him feel that his being in the Chair was caused by such a world's loss. Lord Kelvin had been so long the central figure of the electrical world that they did not realise how much was due to his gigantic labours in electrical science, and how much the whole of the English electrical community had borrowed from him. Ever since he had himself begun to work at electrical matters, he had known Lord Kelvin personally. He had been associated with him in the work of the Corps of Electrical Engineers, and in the international work of which Lord Kelvin was the world's president, and he knew that it would not be easy to replace him. It was difficult at short notice and in a few words to convey to them how great was the loss the Institution had sustained; but in any event it would have been very hard to express what he really felt and what they all really felt at the death of their President.

He thanked the Council for asking him to fill the gap for the remainder of the session. He would do his best to serve. He was an old man, and not so vigorous as he had been, but he would do his best to make the session a success.

Col. R. E. B. Crompton, C.B., who was previously President of the Institution in 1895, was born in 1845, and is thus nearly sixty-three years of age. The firm of Crompton & Co. was established at Chelmsford in 1878, so that Col. Crompton has been associated with the electrical industry from its very earliest stages. Col. Crompton has always been the moving spirit of the Electrical Engineers Corps of Volunteers, of which he has been commanding officer since the death of Dr. John Hopkinson, F.R.S. His work with the detachment of the corps which served during the last South African War brought him to the notice of the military authorities in connection with steam haulage for transport work, and he has since been acting as technical adviser to the Mechanical Transport Committee of the War Office. In December, 1907, the honorary rank of Colonel was conferred upon him.



AN ELECTRICALLY PROPELLED FIRE ESCAPE

SEVERAL fire brigades in this country have now adopted mechanical traction to some extent, but comparatively little attention has been paid to electrical methods, although a good deal has been done in this direction on the Continent. The principal argument in favour of electric traction for fire appliance is simplicity, and the fact that less skilled attendance is required on the road as compared with petrol-driven vehicles. Electric accumulator traction is particularly suitable for fire brigade service, where the runs of the machine average about three miles per turn-out, and there is no reason why the electrically-equipped car should not be a great success. The electrical equipment, as now adopted, is only used on the non-pumping appliances, that is, the escapes, water towers, and auxiliary brakes for the conveyance of extra men. The electric drive has the advantage of being immediately ready for service. The car can be started at a moment's notice, as the batteries can be kept fully charged, and all that is necessary is to put in the starting switch and move off. These are undoubted advantages compared with the explosion engine method, with its starting handle to turn. In the motor-driven fire appliances recently placed on the market by Messrs. Simonis, of Norfolk House, London, some details of which were given in a Paper read by Mr. Otto Simonis, at the annual meeting of the Association of Professional Fire Brigade Officers at Liverpool last summer, the drive takes place on the two front wheels, by separate motors, through a single reduction internal gear. The motors are so arranged that while one is fixed to the front part of one wheel, the other is fixed to the hind part of the other. The battery consists of 80 cells, which are divided into groups of 10 cells each. These cells are interchangeable, and if any one cell requires attention it can be taken out and replaced at will. From the batteries, cables are led to the switchboard and controller, which latter is actuated by a lever, mounted on the steering wheel. This lever moves on a half-circle, and has nine different positions, five in one direction and four in the other. The first five are for the different speeds ahead, while the latter four are divided, the first two being the two electric brakes, and the other two the reversing speeds, so that in the one lever the driver can perform absolutely all the manipulations that are required for the handling of the machine. The front wheel drive has been adopted, as the most natural method of driving, and many advantages are claimed for it. In the first place, power is said to be saved by driving on the front wheels, and in the second place a fuller steering lock can be secured, as the front axle can even be placed directly sideways to the body of the machine, so that extreme turning capacity is obtained, which is vastly important in such appliances as fire escapes. There is one more point in favour of the front-wheel drive, and that, under most circumstances, is, it reduces liability to side slip. It stands to reason that if in going round corners the front and driving wheels draw the machine, the hind wheels will readily follow in their track, but if the drive is on the hind wheels the tendency of the power is to push the machine in a different direction to the front wheels, being steered sideways, and consequently the hind part of the machine swings round. The front wheel drive is also better adapted for get-

Digitized by Google

ting out of the gutter of a sloping road, as the wheels can be put straight, and pull directly out, whereas with the back drive the back wheels tend to push the machine in the straight direction, and the front wheels fail to grip, and cannot pull the machine out.

There are two points to which attention may be drawn: one is that the battery can be carried in a space which otherwise would be of no service, such as between the axles and below the frame, so that the whole of the upper part is available for the accommodation of extra hose pipes, stores, &c. The second point is the comparative immunity against serious damage by collision. The car might get a knock which would place one of the driving motors out of action, but might still proceed at a slower speed by means of the other motor. If the car received a blow which bent the frame, it would not much matter so long as the wheels remained intact. The battery box might even get damaged without seriously affecting the running of the machine, and one or two sets of cells might even be put out of action. The accumulators are capable of allowing 200 to 250 full discharges without attention to the plates, which represents some 6,000 miles' running of the machine, a considerable distance for fire brigade apparatus. A complete set of plates cost about £90, and it is estimated that they would depreciate about 7 per cent.

ELECTRICALLY PROPELLED FIRE ESCAPE AT LIVERPOOL.

of their initial cost per annum, so that about six years may be taken as the serviceable life of the accumulators. The annual cost of the upkeep of an electrically-propelled machine may be roughly taken as follows:—Depreciation of the battery, £15; current for 1,000 miles, at 2d. per mile, £8 6s. 8d.; for acid, oil, washers, and so forth, say £5; in all a total of £28 6s. 8d., which will compare very favourably with the maintenance and cost of upkeep of the petrol-driven car, and very much more favourable than the steam-driven car, where it is always necessary to keep steam up. Among the important cities on the Continent where electric traction for fire brigade purposes has been adopted are:—Hanover, Munich, Charlottenburg, Schoneburg (Berlin), Offenbach, Duisburg, Leipsig, Paris, Basle, and, last of all, Vienna, which was the pioneer of motor-driven fire appliances, and has 21 self-propelled fire vehicles, of which 19 are driven by electricity. Glasgow was the first city in the British Isles to employ an electrically-propelled fire escape, but this is on petrol-electric principle, in which accumulators are not used.

The accompanying illustration represents a large electrically-propelled fire escape, supplied by Messrs. Simonis to the Liverpool Fire Brigade. The escape is carried on the machine telescoped in four sections, and lying with its trunnions on a steel frame affixed to a turn-table. An automatic device releases the ladders, and in doing so takes the weight off the springs of the carriage. By two men hanging on at the foot of the ladder it will now swing up into the vertical position, when the current from the batteries is switched over to the electric motor, built in at the foot of the main ladder, and which, acting on the winches, fully extends the ladder is about 20 seconds, so that the whole manipulation of the machine from its travelling position to its full extent is executed in less than half a minute. But while this is being done, the machine can be turned in any desired direction by means of the turn-table. Standing upright, extended to its full height of 87 ft., the machine will carry one man on top of each section of the ladder giving water with two lengths of hose against the burning building, without any support whatever except its own base, and this can be used most effectively as a water-tower, enabling the Brigade to get on top of the fire when it is quite impossible to lean against the building owing to it being involved in a mass of flame. For rescue work the escape is fitted with devices so that it can be placed at any angle, right down to the horizontal, or even made to form a bridge. It can be quickly shortened and extended again both by the electrical power and by manual labour. The trussing forms a hand-rail all the way up, and quite a number of minor safety devices are attached to the machine. When it is to be lowered again the automatic rung catches, which always fall in position when the ladder is extended, are released, and an oil brake will let the ladders slide down gradually, and allow them to be stopped at any moment.

The New Telephone Charges.—As the result of persistent representations by the various Chambers of Commerce throughout the country, the Postmaster-General has consented to receive a deputation on the subject of the new telephone charges on February 11th. The deputation will probably be received in the House of Commons at about 4.30 p.m., and is expected to include representatives of at least seventy Chambers of Commerce, about thirty Town and County Councils, and several of the leading trade associations of the country. The deputation will be introduced by Lord Joicey, President of the Newcastle Chamber of Commerce.

ELECTRICAL POWER IN RAILWAY GOODS WAREHOUSES

MR. H. HENDERSON, in his Paper read last Monday before the Newcastle Section of the Institution of Electrical Engineers, summed up the chief advantages to be gained by the introduction of electrical power in dealing with goods traffic in warehouses as follows:—(1) More floor space available by making use of overhead travelling cranes. (2) Less aggregate power to perform the same work as hydraulic. (3) Less cost of power. (4) After the machinery is in running order, less maintenance is required.

Nos. 1 and 2 are very clearly seen by comparing the equipment of the North-Eastern Railway Co.'s Forth Goods Warehouse, Newcastle, as originally designed for hydraulic power, with that of the company's New Bridge Street warehouse. The

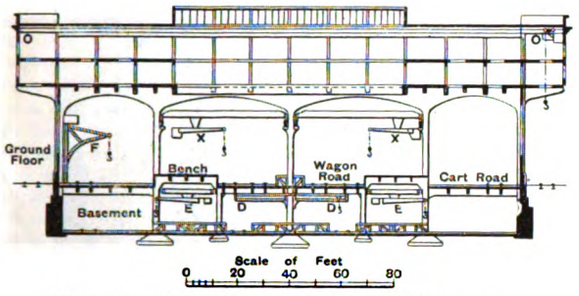

FIG. 1.—NEW BRIDGE STREET WAREHOUSE.

total number of hydraulic cranes at Forth Banks per row of benches was 18, in three rows, making a total of 54. These cranes served benches with an approximate length of 1,500 ft. and an area of about 48,000 sq. ft., which gives 30·3 h.p. per 1,000 sq. ft. of bench area and a lifting capacity of 1·4 tons for the same area.

In the company's new warehouse (Fig. 1) at New Bridge Street, Newcastle, which is designed for electrical working, four electric overhead travelling cranes, described later, serve two benches of a total length of 580 ft. and an area of about 15,000 sq. ft. These cranes give 6·13 h.p. per 1,000 sq. ft. of bench area, and a lifting capacity of 0·27 ton for the same area. These figures show what a great saving can be made by adopting such cranes, and that nine similar electric cranes could have

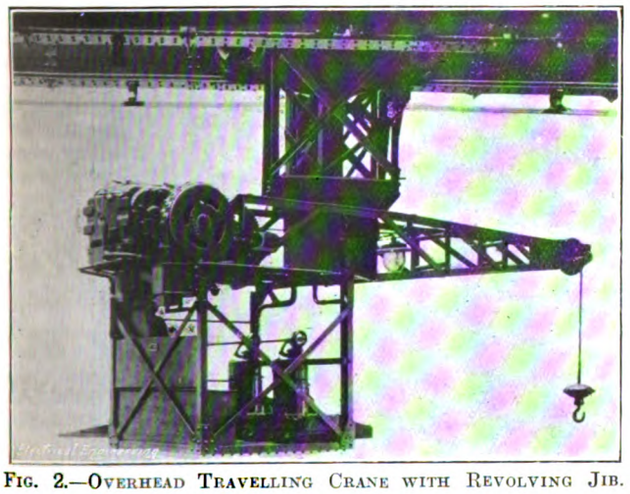

FIG. 2.—OVERHEAD TRAVELLING CRANE WITH REVOLVING JIB.

replaced the 54 hydraulic cranes at the Forth Goods Warehouse, where head room is ample for the use of overhead travellers. The figures cover all motions in each case.

The types of machinery used in a goods warehouse are:—(1) Machinery for dealing with goods, namely: cranes, hoists, &c. (2) Machinery for dealing with traffic, namely: capstans, hoists, and traversers

In describing the different types, the new goods warehouse of the North-Eastern Railway at New Bridge Street will be taken as an example, because it has been designed for electrical working, and the whole of the machinery is electrically driven. Under heading No. 1, a type of crane has been adopted which seems to be most suitable for this class of work. It consists of an ordinary overhead travelling crane, but instead of being fitted with the usual crab, the hoisting gear is attached to a revolving jib carried on a lattice framework fixed to the crab. The crane has thus four motions controlled by two universal controllers fixed to a platform on the revolving jib. The jib, controllers, and hoisting gear are clearly shown in Fig. 2, which also shows the method of suspension from the crab. The lifting capacity is 1 ton, and the sizes of the four motors are:—Lifting motor, 15 B.H.P. at 150 ft. per minute. Revolving motor, 1½ B.H.P. at 250 ft. per minute. Cross traversing motor, 1½ B.H.P. at 150 ft. per minute. Travelling motor, 5 B.H.P. at 350 ft. per minute.

The span is 48 ft. 6 in., and the jib radius 11 ft. From the

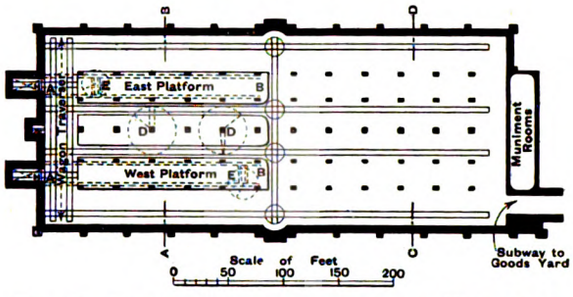

FIG. 3.—BASEMENT, NEW BRIDGE STREET WAREHOUSE.

cross-section of the building shown on Fig. 1, upon which these cranes are marked X, it will be seen that a jib can reach material outside the span of the main girders and do lifting work in three spans of the main building. This is a great advantage, as material can be taken from any wagon and deposited on a cart irrespective of the position of either vehicle. Such work cannot be accomplished by any other type of crane, and at the same time the full command of the whole of the bench is obtained without in any way taking up valuable storage space.

Other cranes on the same floor include two wall cranes shown at F on Fig. 1. These are ordinary revolving jib cranes with stationary machinery and a fixed driving platform. The machinery, consisting of lifting and revolving gear with a separate motor for each motion, is fixed on brackets above the top support of the crane, and the jib is revolved by a vertical shaft carrying a pinion, driving a spur wheel fixed to the top of the crane post. These cranes are capable of lifting 1 ton at

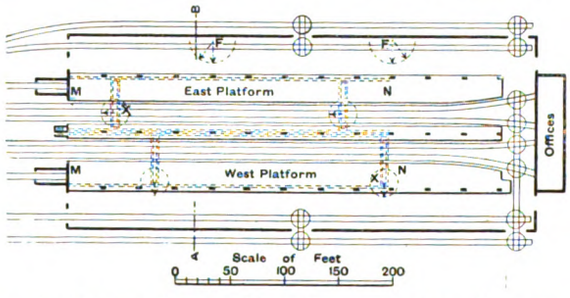

FIG. 4.—GROUND FLOOR, NEW BRIDGE STREET WAREHOUSE.

a speed of 60 ft. per minute with 6 B.H.P., and of slewing at a speed of 150 ft. per minute with 1½ B.H.P. The motors are driven by a double controller with a single handle, as in use on the travelling cranes.

In the basement four cranes have been erected, and, owing to the smallness of the head room, special types have been used. Two of the cranes are travelling jib cranes, similar to the ground floor. These are shown at E on Fig. 4 and in further detail on Fig. 5. In these cranes the revolving jibs are 12 ft. radius, and the span is 20 ft. They can thus cover a width of nearly 40 ft. and have a track 200 ft. long. The capacity is 1 ton and the sizes of the motors are:—Lifting motor, 6 B.H.P. at 60 ft. per minute. Revolving motor, 1½ B.H.P. at 150 ft. per minute. Cross traversing motor, 1½ B.H.P. at 100 ft. per minute Travelling motor, 2¼ B.H.P. at 100 ft. per minute.

It will be seen that the hoisting gear is forward on the jib in this case, and a heavy balance weight attached at the back. This is done to keep the controlling platform up, on account of

Digitized by Google

the small amount of head room available. The remaining two cranes in the basement are of a special type, and are named revolving pillar cranes. They are shown at *D* in Fig. 3, and a full view of the crane and circular track is shown on Fig. 6. Each crane consists of a revolving framework, one end of which is constructed to encircle one of the main pillars of the building, whilst the other is fitted with wheels which run on a circular track attached to the roof. The cage and hoisting gear are fixed

the warehouse. These machines are shown at *O* in Fig. 1. The hoisting gear is contained in a travelling crab, which also carries the cage. The track is formed of heavy channel irons bolted to the roof girders and to the concrete roof, the running rails being bolted to the bottom flange. The lifting is done with a 15-B.H.P. motor, at 150 ft. per minute, and the travelling with 1½-B.H.P., at 350 ft. per minute, both motors being driven from one controller. The lifting capacity is 1 ton. These hoists can

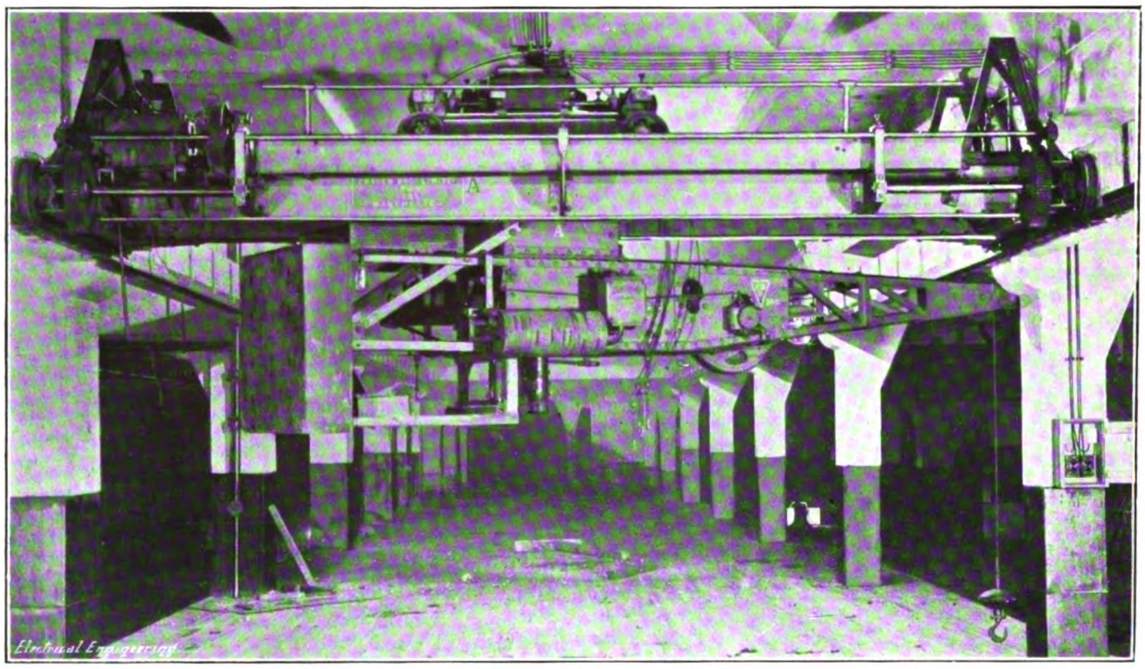

FIG. 5.—OVERHEAD TRAVELLING JIB CRANE.

near the pillar to the revolving frame, and the travelling motor is at the outer end near the wheels, the two motions being driven from one controller. The pillar end of the frame runs on a heavy casting which, when bolted up, forms a vertical circular support carrying a square horizontal flange on the bottom. The end of the frame surrounds this support and carries two rollers which bear on the vertical surface, thus keeping the motion circular. These cranes are capable of lifting

pick up material from any part of the ground floor directly beneath them, and can deposit it on either of the upper floors, the wire passing through a slot in the floor when travelling from the well to the first floor. In the jiggers the machinery is fixed. A heavy H-iron is bolted to the roof, and along this travels a small framework for bringing in the load from outside either to the first or to the second floor, and in two cases to a third floor also. These hoists are shown in Fig. 7. The hoisting rope is

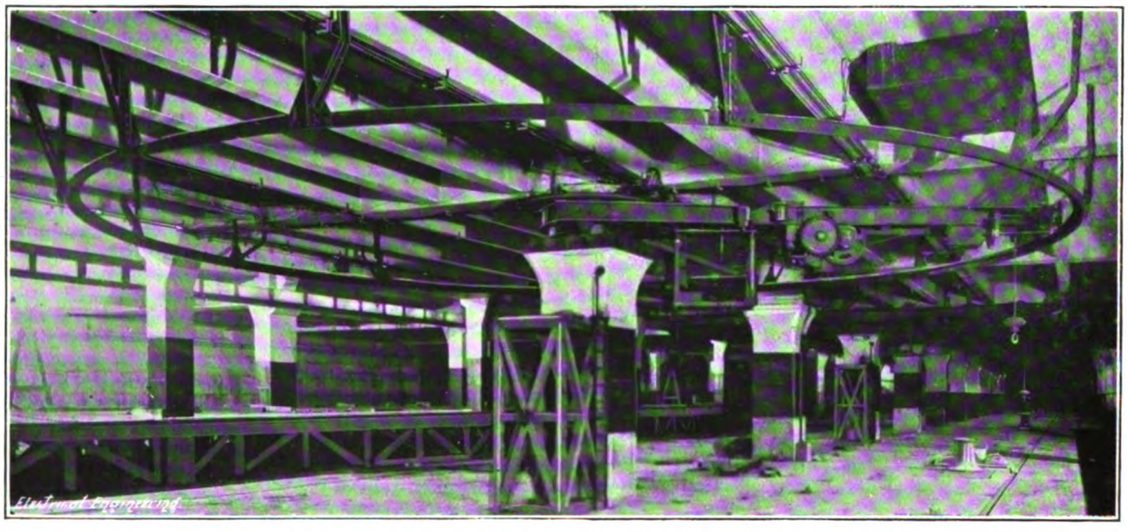

FIG. 6.—REVOLVING PILLAR CRANE.

1 ton at 60 ft. per minute with 6 B.H.P. and revolving at 150 ft. per minute with 1½ B.H.P.

For hoisting material to the top floors, which are used for storage of grain, flour, and similar materials, there are in use two transporters and six jiggers. The transporters travel the full width of the building at about 70 ft. from the ground-floor rail level, the track being extended 16 ft. on each side of the building to permit the hoisting of material from wagons outside

permanently fixed at one end to the outer end of the girder, and passes through the travelling frame over two pulleys to the fall block, and thence to the winding drum. The travelling motor drives an endless rope attached to the frame, running it in or out as required. A large pulley is fixed at the outer end of the girder to take this rope. The capacity is 15 cwt., and the lifting is done with 10 B.H.P., at 100 ft. per minute, and the travelling with 1½ B.H.P., at 120 ft. per minute. These jiggers

Digitized by Google

are made to be controlled from each floor, and also from two places on each floor, namely, one inside and one on a platform outside. The various points of working are interlocked in such a manner that the controllers can only be worked from one point at once. This is done mechanically by gear-wheels and clutches, the various points being coupled by wire ropes driving small shafts with bevel wheels, and finally driving two controllers. All these machines, with the exception of the jiggers, are driven by universal controllers.

Machinery for Dealing with Traffic.—The capstans, which number 42, are designed for a pull of 1 ton, or six loaded wagons averaging a total weight of about 90 tons, at a speed of 250 ft. per minute. The motors are 26 B.H.P., and are compound wound, the series winding being on two poles and the shunt on the remaining two. The starting switches are operated directly by the treadle, a strong dashpot preventing too rapid movement of the switch. The switch also contains an overload release, which brings the switch to starting position and necessitates the treadle being released before the motor can be started again. This works very promptly, and prevents rough usage of the capstan. Whether this type of starting switch is the most desirable one for electric capstans is a debatable point. Electric capstans cannot be roughly treated as hydraulic capstans can. In the latter, if the capstan is overloaded (a very frequent occurrence), no harm is done to the capstan, and the load must be reduced until the power of the capstan is sufficient for the load before any movement will take place. Such methods of working cannot occur with an electric capstan, and unless a protective device is provided damage will occur to the apparatus. Provided the overload release is kept in order, the operator, however careless, will soon learn that the capstan must be treated with respect if any work is to be got out of it. Another serious objection to the direct operation of the starting switch by the treadle is that the necessity of gradually depressing the treadle tends to take the man's mind off his work, which is by no means without danger; also, owing to his having to work against the dashpot and balance weight attached to the treadle, he may not cut out all the resistance, which will burn out after a few such operations. The preferable method is for the treadle to operate a main switch only, the starting switch being automatically worked either by a magnetic coil or by gearing from the motor spindle. The movement of the treadle then becomes a single one, as in hydraulic capstans. Another point which seems to be overlooked in capstans is the space allowed in the cast-iron tank. Capstans are often designed so small that it is impossible to get into them, and any work on repairs or alterations necessitates working in most awkward positions, where sight of what is being done is almost impossible. This is a great mistake. If the capstan is inside there is no reason why it should not be covered in by light plates, which can be easily removed and the whole of the mechanism exposed. With outside capstans this would not apply, but the difficulty can be got over in a different manner. The author recently had the privilege of seeing several capstans in a goods yard in Lancashire which were excellently arranged. The tank was of a double pattern, fixed end to end, these ends being cut out to form a communication between the two. The tanks were very deep, and one of them was covered with a heavy lid in one piece, which carried the motor and the capstan head. The switch-gear was also fixed in the same tank, and consisted of a double-pole switch worked from the treadle, a starting switch from the motor spindle, and a switch which short-circuited the armature when the treadle was off, thus acting as a brake. The second tank was covered with light plates, and simply contained the outlet to the drain, and a ladder for descent. Thus access was easily gained to the capstan proper, and it was possible to pass in underneath the motor and capstan head and do any work required in comfort. All the apparatus was thus under a cover, which did not require to be removed, was easily got at, and there was room to deposit any parts which required to be taken down. Objection may be taken to the expense of having to dig a deeper hole for the tanks, but the advantages gained easily outweigh such objection. If all electric capstans were designed upon this principle it would do much to remove a number of the troubles which occur with electric capstans in practical working. In the 42 capstans at New Bridge Street the head is driven by bevel gearing, and the shaft of the armature is fitted with an electro-magnetic strap brake in series with the motor operated for braking by a heavy balance weight when the current is cut off.

Wagon Hoists.—As will be seen from Fig. 3, the only access to the basement for railway wagons is by way of the wagon hoists. These are worked electrically, and are capable of lowering 30 tons and lifting 20 tons. They are controlled on the push-button principle, and are probably the largest hoists of that type ever made. The hoisting arrangement is very simple, being, in reality, two sets of huge pulley blocks. The usual method of operation is, however, reversed, and that block which is generally fixed is in this case the movable set, and the load is raised by means of the tail end rope. Its use in connection with a hoist, especially of such a size, is indeed very novel. The machinery, which is at the top of the hoist, is composed of two exactly similar parts, each driven by a 50-h.p. 240-volt compound motor, the motors being connected in series. Each motor is coupled to its gearing by means of a shaft carrying a magnetic strap brake and also a high-speed centrifugal brake, to check too rapid motion. The gearing finally drives a large-toothed wheel, which has teeth over about $\frac{3}{8}$ of its rim, the remaining part being simply flat. The two parts of the machinery are coupled together by means of a heavy crank-pin, forming a complete engine, and leaving a space of about 3 ft. 7 in. between the large-toothed wheels, in which the ropes are operated. To this crank-pin are attached the ends of the four ropes which hoist the cage, and also the ends of the ropes connected with the balance weights which balance the load. Starting with the ends, the two ropes are attached to the crank-pin. From thence they pass over a fixed pulley at the side (both ropes running in one groove). From this pulley they pass over the pulley on the crank-pin and back to a second fixed pulley, after which they pass over "dumping" pulleys to the

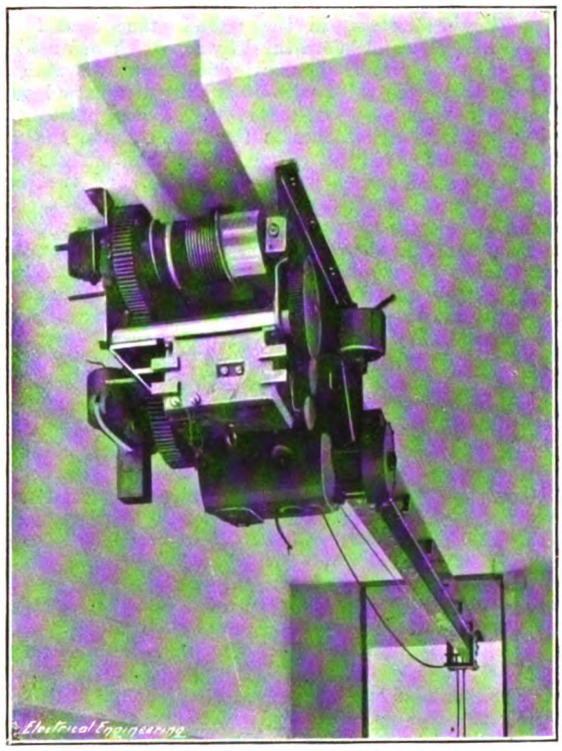

FIG. 7.—TRAVELLING CRAB.

top of the cage, the double rope opening out so that they may be attached to each side of the top beam. The ropes then return from the pulleys attached to the cage to the second set of blocks, finally being made off at the opposite end of the crank-pin to which they started. The switch-gear is of Messrs. Smith & Stevens pattern, operated from push-buttons on the ground floor and from a set of push-buttons in the cage. The speed of the hoists is 60 ft. per minute and the lift 18 ft.

After the wagons are lowered to the basement floor they are received by a large traverser. This machine runs in a special pit 30 ft. wide and the full width of the building, as shown on Fig. 3. The traverser consists of a large platform 27 ft. long and 18 ft. wide, running on eight large grooved wheels on four sets of rails. There are also two sets of roller wheels running on the same rails to take the centre weight and that of the driving platform. Upon one side, which is extended and fitted with a hand-rail, is fixed the motor which drives the traverser, and also a capstan head for drawing wagons on to the traverser from the hoists. The motor is 26 B.H.P., driven by a simple reversing controller. The motor drives a shaft fitted with a double-clutch gear. One clutch drives the nearest shaft which carries the running wheels, and the other clutch drives the capstan head. The clutches are operated by one hand-wheel, so that both motions cannot be used together. The clutch connecting the capstan head is arranged to drive the head in one

Digitized by Google

direction, the reversal of the motor driving the shaft only, the arrangement being similar to that of a free-wheel. Current is carried to the motor through collectors fixed underneath the floor of the traverser and running in a conduit carrying the bare wires. The speed of the traverser is 300 ft. per minute, and the capstan speed 200 ft. per minute.

The power is taken from the Newcastle Electric Supply Company's Pandon Dene sub-station at a pressure of 480 volts between the outers. All the power is supplied at this pressure and the lighting at 240 volts. The whole building is controlled from two switchboards, one for power and the other for lighting, a separate account being kept of the energy used for each.

With regard to the cost of electrical working, the New Bridge Street Warehouse has not yet been in use to any large extent, so that no figures can be given. Some interesting figures are, however, given below with respect to a goods warehouse in the South-West of England. This warehouse originally contained 50 hydraulic cranes and six hydraulic capstans. Before deciding to electrify the cranes, &c., experiments were made to ascertain which cranes and capstans used most of the water. It was found that three of the cranes, and the six capstans, used 90 per cent. of the water. It was then decided to electrify these and drive the remaining cranes with electrically-driven pumps. The cranes were electrified by fixing a lifting and slewing gear on a fixed framework underneath the bench, utilising the old crane posts and jibs. In one case the old hydraulic controllers were used to work liquid starters, in the second crane special liquid starters were fixed, and in the third crane, which was used most frequently, ordinary controllers with wire resistances were used. The two pumps were fitted with 15-B.H.P. motors and worked automatically from float switches on the accumulators. By means of change-over switches in the float circuits, the pumps and accumulators could be grouped as desired. These alterations were carried out at a cost of £1,157, and the cost of working fell from £600 to £150 per annum. The saving of labour in such cases is very great, especially if the power is taken from a public supply, as is done in the case mentioned, the rate being 1d. per unit. This shows what a great saving can be made by means of electric driving even by converting steam or gas-driven hydraulic pumps to electrically-driven pumps, and working these by automatic switches.

Under the heading of conversion of plant may be added a change which was made at the Forth Goods Warehouse, Newcastle. Upon the benches are a number of hatchways for the cellars, and the hydraulic cranes are arranged so that most of them can lower material into the cellars. It was decided to experiment on one row of benches with electric cranes. A crane of the transporter type was designed, and the track laid out in such a manner as to pass over the roadway, benches, and railroad, and at the same time to pass vertically above the principal hatchways. This necessitated a specially curved track. The track is made of channel iron and carried on a series of lattice girders attached to the roof columns. Current is conveyed to the motors on the transporter through the track rails, which necessitates the insulating of each support. Some difficulty was experienced with this at the commencement, due to the vibration breaking down the insulated bolts. This trouble was easily got over by using hard red fibre plates, and bushing the holes with two fibre tubes and washers, one tube sliding within the other. This made an excellent joint, and no trouble was experienced afterwards. The transporter consists of a small bogie running on four wheels and driven by a vertical motor fixed on top of the framework. To the underside of this framework are attached the cage and lifting gear. As there is a difference of 480 volts between the rails, the wheels have to be insulated from the axles. Brushes press on each wheel and carry the current to the motors and the controller, which is of the universal type previously described. The lifting capacity is 1 ton, and the lifting is done with a 15-B.H.P. motor, the travelling motor being 3 B.H.P. There are two transporters on the track, and these displaced eleven hydraulic cranes. They work very well and can easily perform the duties which were previously done by the hydraulic cranes. The number of units registered against these cranes averages 350 per month, which is very small, and if the wages of the boys who drive the cranes are added, the total cost taken at the power rate of most supply companies would be insignificant compared with that of the number of hydraulic cranes displaced.

Mr. Henderson, in referring to the costs of electrical working at the New Bridge Street warehouse, said :—Since this Paper was written I have taken a few tests with the following results. Taking the transporter lifting cage on the top floor (15 b.h.p. motor running 350 r.p.m. with 1 ton lifting capacity), 4 tons 10 cwt. of bran were lifted 40 feet with an expenditure of 1·27 units. Four bags, equivalent to 4 cwt., took energy working out at 0·327 unit per ton. Six bags or 6 cwt. took 0·244 unit per ton. Tests on the jigger showed, in lifting 10 tons of flour in 20 lifts through 50 feet, 0·164 unit per ton. The time of each hoist was 26 seconds.

He also showed a special capstan starting switch as fulfilling conditions better than the usual dash-pot and arm-swinging over-contacts. This starter is shown diagrammatically in Fig. 8; the principal parts consist of a solenoid, a plunger with retarding dash-pot, and a number of levers hinged to the lower pole-piece of the solenoid. The upper ends of the levers carry the carbon contacts. The levers are controlled by their lower ends passing through a frame which is attached to the bottom of the plunger. The solenoid, becoming energised by the closing of the small controlling switch, begins to lift its plunger, the motion of which is retarded by an air dash-pot. As soon as the frame, which is attached to the base of the plunger, begins to move, one of the levers is released, and this lever being attracted by the magnetic flux of the solenoid makes the field and contact. As the frame travels still higher another lever is released, which, in its turn, is attracted and cuts out a step of resistance, and so on, one lever after another being attracted until the entire amount of resistance in series with the armature circuit is short-circuited or cut out. When the circuit to the solenoid is opened, the plunger with its attached frame drops. As the frame goes down the lower ends of the levers are pulled inward, breaking the contacts in the reverse order in which they were made. As the contacts are broken the resistance is inserted in the armature circuit, so that the resistance is all inserted when the last lever breaks the main-line contact.

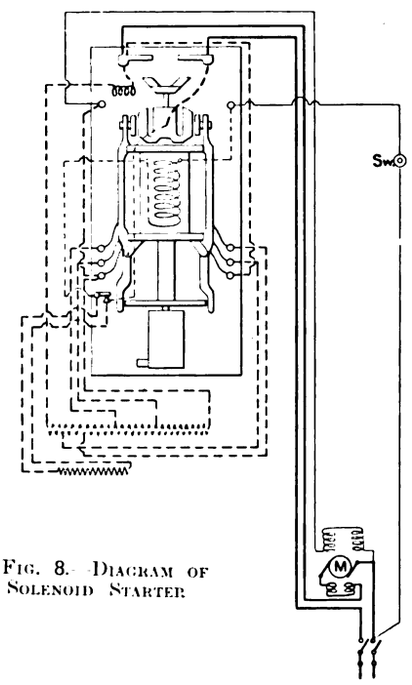

FIG. 8.—DIAGRAM OF SOLENOID STARTER

DISCUSSION.

MR. F. O. HUNT referred to the control of the jiggers, pointing out that this was accomplished by means of wire rope. It would seem as if the more direct way would be by a system of electrical multiple control in the same way that push-button lifts are operated. Relays with electrical transmission might be employed. With reference to the electric capstans employed, especially in out-door situations, the wide changes of temperature to which they are subjected must produce much condensed moisture within, and he suggested that the question of supervision of the switchgear would be important with the arrangement shown. No one but a trained acrobat could make a good contact in some underground chambers below capstans. This point was of influence in producing an opinion as to the reliability of electric capstans, as, although they are not really frail, they are sometimes put down as faulty owing to lack of proper supervision. In the case now discussed, as the capstans are not out of doors, it would be better to put nearly the whole of the control gear above ground on a wall or pillar, which would probably be near at hand, making maintenance easier. He also wished to know why the makers of the waggon hoists had inverted the usual block and fall system. The good point of this inversion—that one cannot lift the cage above a certain point—had not been utilised by the makers. The

Digitized by Google

drawback to the arrangement was that the large steel ropes passed round small pulleys with a reverse bend. Under these conditions ropes wear out four times as fast as if they were bent in one direction.

Mr. J. ANDERSON asked for information as to the units consumed, the kilowatts demanded, and the financial results. He gathered that the author had had trouble with his capstans, and wanted to know if this was at the commutator or confined to the starter. He would like to know if circuit-breakers were freely used in the installation. He regarded the switchgear for the waggon hoists as rather complicated, and asked if liquid starters had been considered. He also wished to know if three-phase working had been considered. All motors but the hoisting motors on the overhead travellers could have been squirrel cage, and no complicated starting-gear would have been needed. The motors would, of course, be larger with three-phase work to give sufficient starting torque. The capstans would undoubtedly have been better if driven by three-phase motors. They would have stood rougher usage, as the only limiting factor would have been the load at which the motors would burn out. With regard to the capstans, were they started up on load or with a slack rope? The waggon hoist could have been run by small transformers and relays. Three-phase motors would have been cheaper and more easily maintained.

Mr. C. FARADAY PROCTOR, referring to the unique arrangement effected in the conversion of the Forth Goods Warehouse, wished to know what special precaution had been taken against damp in using fibre insulation.

Mr. HOLLIS asked the speed of the capstans; were they direct-driven from the motors? He also referred to the field winding on the compound-wound machines, and wished to know why the shunt and series windings were placed on different poles. What was the load factor on the installation? Were cut-outs or fuses used on the motors? If the latter, were the fuses of the cartridge type?

Mr. CLOTHIER congratulated the N.E.R. on the saving effected in power by adopting electric drive, and wished to know the further saving through economy in space. He thought a chamber eight feet deep involved rather a tremendous amount of excavating for a capstan, and suggested as an alternative that the motor and gear should be fixed to the underside of the chamber cover, which could be raised by screws some three or four feet for inspection purposes.

Mr. W. CROSS also referred to the difficulty of getting at the electric capstans, and asked why the arrangement adopted in hydraulic capstans was not followed. In these the whole of the gear is fixed to the lid of the tank, and the lid suspended on pivots, enabling the whole gear to be slewed round for inspection. The switchgear shown seemed a little complicated. Capstan resistances should be designed so that they could be left in circuit, if necesary, for half an hour.

Mr. LONGMAN, referring to the compound wound capstan motor, asked if any sparking between brushes occurred through having the shunt and series windings on separate poles. He also requested information as to the cost of upkeep of the special switch shown, and asked whether the 240-volt motors of the hoists which were connected two in series had any mechanical connection between their shafts. He would like to know the reasons for adopting direct current in preference to three-phase supply.

THE CHAIRMAN (Mr. PIGG) interposed to say that the design of the warehouse was settled six or seven years ago, and contracts placed; other things had intervened. When the actual building was commenced the designs were again considered, but for commercial reasons, in spite of the advance in three-phase work, it was decided to adhere to direct current.

Mr. CLAGUE detailed some experiments he had made on red fibre, and asked what special means were taken to make its use possible.

Mr. PIGG explained that the fibre was heavily shellaced.

Mr. HENDERSON, in reply, said that, owing to special conditions, such as the amount of work involved in removing goods from box waggons, the mechanical control of the jiggers was considered better. He agreed that, wherever possible, the switchgear should be fixed outside capstan tanks. The chief trouble in capstans was moisture, and where the electrical gear was hard to get at, the cost of maintenance was doubled. The cost of the tanks described was not heavy, and was merely a capital charge, while excessive maintenance due to shallow tanks went on as long as the plant was used. The power factor could not yet be determined, as the place was not yet in full use. There were automatic circuit-breakers on each capstan, and breakers controlling the main power circuits, branches of which were protected by fuses. Trouble was sometimes experienced by a small fuse, flashing over to terminals, pulling out the big main cut-outs. The capstans were never started with the rope tight on, as the man would then have a chance of being pulled into the capstan through dividing his attention between his foot treadle and the load. He recommended a form of switch, such as that on the table, the treadle of which could be at once pressed home, and relieve the man's mind as to the gradual starting up of the motor. With regard to the traverser at the Forth Goods Station, he admitted the design was unusual, but by bushing the wheels with dished mica bushes secured by insulated bolts, and paying attention to the insulation of the rails, no trouble had been experienced throughout a run of four or five years. The capstan motors were connected direct to the head. The reason for placing the shunt and series windings on separate poles of the four-pole motor described was that the depth of the poles was limited by the space at disposal. There was no trouble due to flashing over between brushes. The wiring of the building was open, on porcelain cleats, except where there was danger of crushing or abrasion, when metal tubing was employed. The principle of mounting the capstan electrical gear on the tank lid, this being placed on trunnions, was good, provided the motors had grease lubrication. The 240-volt motors on the hoist were mechanically connected through the crank-pin. The object of putting them in series was to simplify the electrical connections.

It was announced that the Paper should have been previously read in London, but, owing to the death of Lord Kelvin, its discussion had been postponed till February 20th.

MAGNETIC OSCILLATIONS IN ALTERNATORS

THE paper read by Mr. G. W. Worrall at the meeting of the Manchester Local Section of the Institution of Electrical Engineers last Tuesday contained the results of the continuation of some experiments detailed in a previous paper (see ELECTRICAL ENGINEERING, Vol. I., p. 263) on the magnetic oscillations occurring in alternators due to the shape and proportions of the machine parts. Such oscillations may be broadly divided into two classes:—(1) The oscillations taking place in the main magnetic circuit; (2) the oscillations taking place locally in the pole-face and air-gap. The first have been shown to be practically independent of the shape of the armature slots and the armature current, while the second were greatly influenced thereby, both in their magnitude and nature.

Although the existence of oscillations of the main magnetic flux has been fully recognised, diverse views have been expressed regarding the conditions determining its nature and magnitude.

There does not appear to be any record of experimental observations of the phenomenon except Fischer-Hinnen's experiments on the humming of dynamos and motors. The experiments of this author show that the pitch of the note emitted corresponds to the frequency with which the teeth pass the pole-shoe, and he concludes that humming is due to the oscillations in the main magnetic circuit. As a result of his experimental observations he gives the formula:—

$$\frac{b - 0{\cdot}7\,r}{(D + 2\,\delta)\,\pi} N = (\text{whole number}) + 0{\cdot}5\,;$$

where b = breadth of pole-face, r = radius of pole-tip, D = diameter of armature, N = number of teeth in armature. This author considers that theoretically the expression should be equal to a whole number, because in that case the reluctance of the magnetic circuit is constant, and he explains his experimental results by assuming that on account of fringing of the flux at the pole-tips the effective is greater than the actual pole width.

The machine employed in the present investigation was the same as that described in the author's previous paper already referred to, *i.e.*, three-phase, lap-wound tapped armature, 4 poles, 44 teeth, speed 1,200 r.p.m., P.D. on open circuit 173 volts. To this machine and for the purpose of the present investigation new pole-pieces were fitted having an arc approximately equal to six times the tooth-pitch. The pole-shoe and limb were laminated and in one stamping. The armature slots were open, $\frac{9}{32}$ in. wide and $\frac{15}{16}$ in. deep; the width of the tooth at the armature surface was the same as the width of slot; the air-gap was 0·118 in.

The magnetic oscillations were observed by means of the E.M.F.'s induced in search coils linking the magnetic circuit. One search coil of 10 turns, wound on a wood frame, enclosed the pole-shoe another of 60 turns was wound round the limb, midway between the pole-shoe and the yoke, and a third of 60 turns round the yoke. The position of the search coil on the pole-shoe is shown in Fig. 1.

As in the author's previous investigation, the E.M.F.'s were photographically recorded by means of a high-frequency Duddell oscillograph and revolving film camera. Since the armature current had been shown to have practically no influence on the

Digitized by Google

magnitude of the oscillations, the machine was run only on open circuit. The polar arc was varied by planing down the tips of the pole-shoes. The planing was done in a direction parallel to the laminations, and with a very sharp tool and fine feed, so as to prevent as far as possible a burr forming over the edges of the laminations. The exciting current was adjusted so as to produce the same magnetic flux in the magnetic limb in the case of each experiment. The flux in the other parts of the circuit also remained nearly constant throughout. Fig. 1 shows the pole-shoe in its various sizes.

The area of the E.M.F. wave induced in a coil represents the periodic increase and decrease of the flux occurring at that

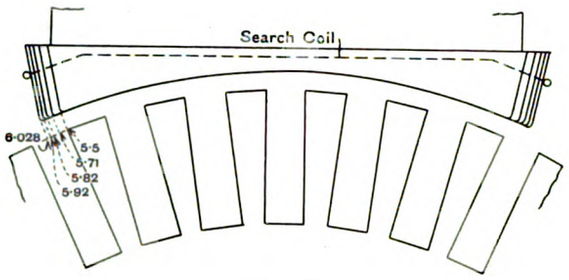

FIG. 1.

point of the magnetic circuit. Fig. 2 represents graphically the value of this change of flux for the different sizes of pole-shoe. It will be noted that the magnitudes of the oscillations occurring in the yoke are approximately one-half those occurring in the limb of the pole; this is, of course, due to the yoke flux being one-half the limb flux. The percentage oscillations are the same in both parts of the magnetic circuit. From these results it will be seen that the magnitude of the oscillations varies through a great range, and that it is a maximum when the polar arc is six times the tooth-pitch and a minimum when the polar arc is five and one-half times the tooth-pitch.

The P.D. wave was oscillographed for each size of pole-shoe, and Fig. 3 shows the half-waves recorded. It will be noted

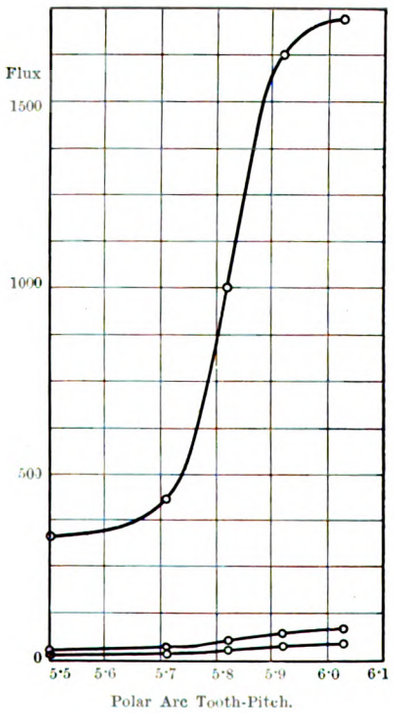

FIG. 2.

that the ripples increase very considerably in magnitude as the polar arc is reduced, and are a minimum when the polar arc is such that the magnetic oscillations recorded are a maximum and *vice versâ*. The P.D. was found to rise as the ripples increased, and the values corresponding to the various waves are indicated thereon.

The general distribution of the field in the case of the smallest size of pole-shoe was determined by means of the E.M.F. wave induced in a coil attached to the armature surface, and of a width equal to the pole-pitch. Each side of the coil was laid over the centre of a slot, and the E.M.F. wave obtained is shown in Fig. 4. It will be seen that the field immediately beyond the pole-tip is very small compared with that under the pole, and hence the stray flux increases the effective polar arc by but a very small amount. The variations to which the main field is subject may be examined by means of the diagrams in Figs. 5 and 6. In Fig. 5 the polar arc equals six times the tooth-pitch, and in Fig. 6 five and one-half times. In the case shown in Fig. 5 the two extreme positions of the armature relative to the pole-arc when (*a*) two slots and (*b*) two teeth are under the pole-tips; the former position is shown at A and the latter position at B.

In position A, since there is very little fringing, the major portion of the flux will only enter the teeth actually under the pole, and hence the boundary lines of the flux will be approximately as shown. In position B the flux will spread out towards the outer edges of the teeth, and the boundary of the flux will be somewhat as shown. Thus the surface through which the flux enters the armature increases from *l m* to *p q* as the latter moves from position A into position B. Hence the arc of the armature under the influence of a pole is subject to a periodic variation in magnitude, and the reluctance of the magnetic circuit, and hence the magnitude of the magnetic flux is subject to a periodic variation also. This magnetic oscillation may therefore be termed "flux pulsation." In the case shown in Fig. 6, when the polar arc equals five and one-half

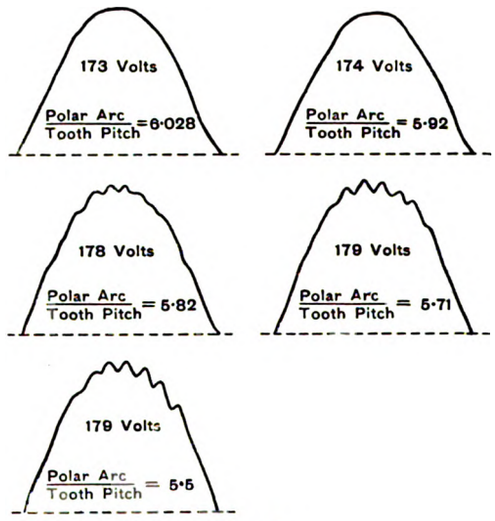

FIG. 3.

times the tooth-pitch, the two extreme positions of the armature relative to the pole are when (*a*) a slot is under the trailing tip and a tooth under the leading tip, and (*b*) a tooth under the trailing tip and a slot under the leading tip; the former position is shown at A and the latter at B. The boundary lines of the flux in the two cases will be approximately as shown. From these latter diagrams it is clear that the surface through which the flux enters the armature remains constant in magnitude, but is subject to a periodic variation in position relative to the pole-piece, giving rise to a to-and-fro swinging of the main flux, which therefore may be termed the "flux swing." Notwithstanding that the principal variation to which the main flux is subject in the two cases is as described, yet it is evident that it is also subject to a slight "swing" in the case shown in Fig. 5 and to a slight "pulsation" in the case shown in Fig. 6. When the proportion of polar arc to tooth-pitch lies between the values given above, the oscillations which occur will include both of the types described, but their magnitudes will not be so great. The "flux pulsation" would affect the whole of the magnetic circuit, but the "flux swing" would affect the air-gap only. Thus it is that the E.M.F.'s generated in the experimental search coils linking the magnetic circuit were a maximum for the case shown in Fig. 5, and a minimum for that shown in Fig. 6. The two kinds of magnetic oscillation of the main flux have now been dealt with, and their effect in generating E.M.F. ripples in the armature coils may next be considered. The frequency of the ripples is the same as that of the magnetic oscillations, *i.e.*, equal to the number of teeth passing a pole per second; in the case of these experiments the frequency was 880. When the flux is subject to a "pulsation," the E.M.F. ripple generated in an armature coil will be in proportion to the flux linked by the coil. The flux linked is a minimum when the centre of the coil coincides with the neutral line, and is a maximum when it

Digitized by Google

coincides with the centre of the pole-face. Hence the E.M.F. ripples will be a minimum in the former position and a maximum in the latter. On the other hand, the main E.M.F. generated in the coil due to the rotation of the armature will be a maximum in the former position and a minimum in the latter. Hence, in the case shown in Fig. 5, the ripples in the E.M.F. wave will be a maximum as the wave crosses the zero line, and a minimum in the crest of the wave.

When the flux is subject to a "swing," the E.M.F. ripple will be generated in an armature coil only as the sides of the latter are actually cutting the flux, that is, when they are under the pole-face. Hence, in the case shown in Fig. 6, the ripples in the E.M.F. wave will be a maximum in the crest and a

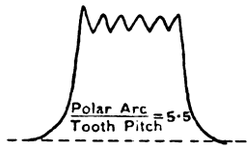

FIG. 4.

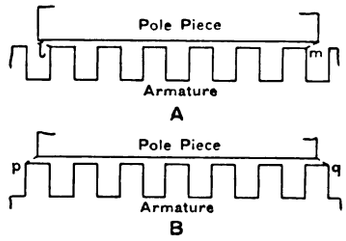

FIG. 5.

minimum as the wave crosses the zero line. This case is very clearly illustrated in the E.M.F. wave shown in Fig. 4, already referred to.

In considering the summing-up effect of the armature coils, distinction must be made between the two principal types of winding, *i.e.*, the open circuit and the tapped continuous-current winding. In the former the E.M.F. ripples in successive coils will add up in the same way as the main E.M.F.'s, and therefore in this case the remarks made on a single coil apply to the whole armature. In the latter the main E.M.F. is a maximum when the tapping points are in the neutral plane, and a minimum when they are opposite the middle of the pole-face. In the former position of the tapping points the "pulsation" of the main flux will induce E.M.F. ripples in the conductors of any armature circuit which will cancel each other and so give no resultant P.D. between the tapping points, while the "swing" of the main flux in the air-gap will induce E.M.F. ripples which will add up and give a resultant P.D. between the tapping points. In the latter position of the tapping points, and when the main E.M.F. is zero, the "pulsation" of the main flux will induce E.M.F. ripples in the conductors of any armature circuit which will add up and give a resultant P.D. between the tapping points, while the "swing" of the flux

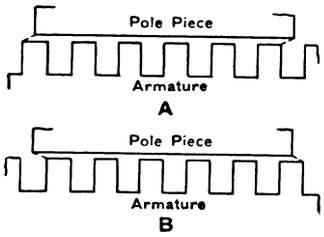

FIG. 6.

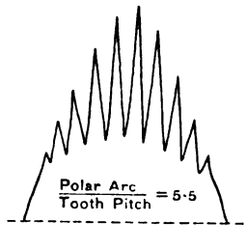

FIG. 7.

will induce E.M.F. ripples, which will cancel each other and so give us resultant P.D. between the tapping points. Thus it appears that in all types of armature winding the ripples in the crest of the wave are due to the "flux swing," and those in the zero portion of the wave are due to the "flux pulsation."

This effect may be made more apparent by intensifying the ripples in the P.D. wave by means of resonance. Fig. 7 shows the resonance P.D. obtained in the case of the smallest polar arc, from which it will be seen that the zero portion of the wave is practically smooth. In order to ascertain if this effect occurred in the case of other machines, several generators were oscillographed. Fig. 8 shows two of the half-waves recorded. A is the P.D. wave of a single-phase generator with rotating field; the ratio of polar arc to tooth-pitch was six, the air-gap was slightly greater at the tips than at the centre of the pole-face. It will be seen that the crest of the wave is practically smooth, due to the absence of "flux swing." B is the P.D. wave between neutral and line of a three-phase generator with rotating field; ratio of polar arc to tooth-pitch was very slightly greater than five and one-half, the air-gap was constant over the whole pole-face, but the tips of the pole-shoes were very thin. It will be noted that the ripples are very strong in the crest of the wave, due to the "flux swing" effect, but diminish towards the zero portion. The ripples cover a somewhat larger arc of the wave than in the case of the author's experimental machine, on account of the special nature of the winding. Thus similar results have been obtained from three machines widely differing in construction, and it may therefore be concluded that the experimental results given in this paper are of general application.

Local Oscillations of the Magnetic Flux in the Pole-face and Air-gap.—In the experiments described in the author's previous paper, already referred to, the phenomenon of "phase displacement" was observed. This phenomenon has now been more fully investigated and the displacements measured, and it may be well to introduce this part of the subject in hand by repeating briefly here the description of the phenomenon given in that paper. When the conductors in a slot under the pole-face carry current, the local magnetic flux generated by the current has two paths open to it: the one lies across the slot and the other across the air-gap from one tooth-top to the pole-face and back to the next tooth-top. In the case of an open slot armature the reluctance of the latter path, in proportion to that of the former, is usually such that the major portion of the flux proceeds that way. The local flux in that case strengthens the main flux, entering one tip of a tooth, and weakens that entering the other tip. Thus the line of symmetry of the flux is slightly displaced. This effect was called by the author "flux displacement." In the investigation forming the subject of the previous paper search coils were attached to the pole-face for the purpose of observing the local magnetic oscillations due to the passing of the armature teeth; one side of each coil was attached to a N-pole and the other in a corresponding position to an adjacent S-pole; the sides of the coils were parallel to the axis of the armature. When "flux displacement" occurred the phase of the E.M.F. wave generated in a search coil was slightly changed in its relation to the armature teeth. This effect was referred to as "phase displacement."

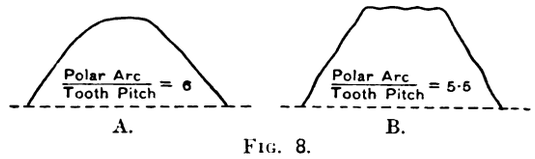

FIG. 8.

In the present further investigation of this phenomenon the machine employed was that already described in the opening remarks of the present paper. Three search coils were attached to the faces of adjacent poles, *i.e.*, one of a single turn in the centre and one of three turns each of the pole-tips. The E.M.F.'s generated were photographically recorded by means of the oscillograph, and a definite position of the armature was instantaneously marked on the record by means of a contact-maker of special design. The construction of this is shown at Fig. 9. It consists essentially of three parts, the steel spring S, the copper gauze C, and the moving steel contactor K. This last is attached to an arm on the machine shaft (not shown) and rotates with it, while the spring S and the gauze C are stationary. The three parts are so adjusted that the contactor K at the same instant flicks the tip of the spring S and rubs the gauze C. Fig 10 shows the diagram of connections. R is the contact-maker, P is a pair of strips of the oscillograph, T is a search coil, and L is a small accumulator. It will be seen that at the instant of contact the accumulator L is connected in parallel with the search coil T, and hence the current flowing through the oscillograph strips will be momentarily altered, producing a sharp break in the continuity of the E.M.F. wave being recorded. Fig. 11 shows a record obtained; the break in continuity occurs at P, and this point corresponds to a definite position of the armature relative to the search coil,

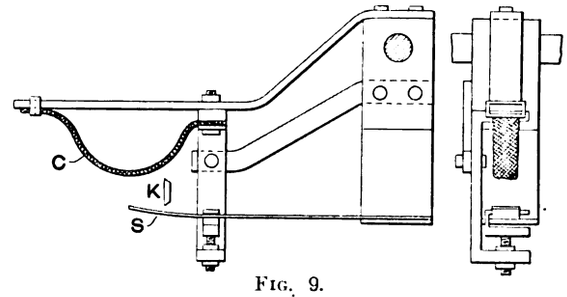

FIG. 9.

Digitized by Google

Only one contact was made in each revolution, and each oscillograph record represented a complete revolution of the machine. The accuracy of the contact-maker was tested from time to time, and proved by the exact repetition of previous records.

When the machine was on load and the armature conductors passing the sides of the search coil carried current, the E.M.F. wave generated was found to be slightly displaced from its position on open circuit relative to the contact mark on the record. This change of position, as measured on the oscillograph record, gives the displacement of the line of symmetry of the flux, or "flux displacement."

Table I. gives the displacements observed expressed as a percentage of the tooth-pitch. In this table the positive sign indicates a forward displacement of the E.M.F. wave on the oscillograph record and hence a backward displacement of the flux relative to the armature. It will be noted that in the case of non-inductive load the displacements are all positive,

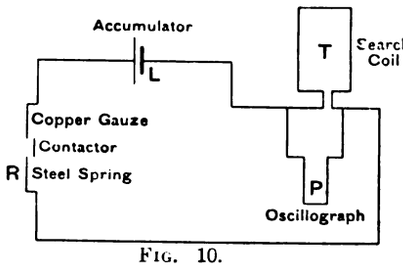

FIG. 10.

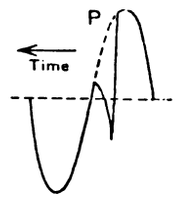

FIG. 11.

while in the case of inductive load the displacements change from positive through zero to negative in passing from the trailing tip to the leading tip of the pole. This is due to the distribution of current under the pole-face. When the load is non-inductive the current is in the same direction as the main E.M.F. generated, and hence strengthens the flux in the rear tip of a tooth and weakens that in the forward tip. When, however, the load is inductive the current under the centre of the pole-face is zero, and that under the leading tip is in the opposite direction to the main E.M.F.

It will be further noted that in the case of non-inductive load the displacements are greatest under the leading tip and diminish towards the trailing tip. This is probably due to the main armature reaction flux weakening the leading and strengthening the trailing tip of the pole. As successive slots pass a given point in the pole-face the armature current opposite that point would not be quite constant, but the flux displacement was not found to vary within the possibilities of measurement. In a single-phase generator, however, the variation of current and hence the variation of "flux displacement" would be very great. "Flux displacement" would cause the distribution of eddy currents over the pole-face to vary between no load and full load and with various power factors, and hence the eddy current loss would be also subject to a variation. The periodic variation of the "flux displacement" as successive

TABLE I.

Load.	Leading pole-tip.	Centre of pole-face.	Trailing pole-tip.
Open circuit	0	0	0
Non-inductive half-load	+8·0	+6·5	+3·0
Non-inductive full load	+15·0	+10·7	+4·1
Inductive half-load	−2·3	0	+2·8
Inductive full load	−4·5	0	+4·1

slots pass a given point in the pole-face would cause the eddy current distribution and hence the eddy current loss to vary periodically also. The magnitude and frequency of this latter would depend upon the type of winding and the number of phases possessed by the machine.

The results of the investigations described in this paper may be briefly summarised as follows :—

1. There are two kinds of magnetic oscillation in the main magnetic circuit :—(*a*) A variation in magnitude or "flux pulsation"; (*b*) a to-and-fro movement of the flux or "flux swing."

2. "Flux pulsation" is a maximum when the ratio of polar arc to tooth-pitch equals a whole number, and is a minimum when the ratio equals a whole number plus one-half.

3. "Flux swing" is a maximum when the ratio of polar arc to tooth-pitch equals a whole number plus one-half, and is a minimum when the ratio equals a whole number.

4. The ripples in the crest of the P.D. wave are due to the "flux swing" and those in the zero portion of the wave to the "flux pulsation."

5. When the armature carries current, the flux entering the teeth is displaced (*a*) backwards, when the current is in the same direction as the main E.M.F. generated: (*b*) forwards, when the current is in the opposite direction to the main E.M.F. generated.

The author expresses his thanks to Messrs. Thomas Parker, Ltd., for the loan of the machine and special pole-pieces, and to Professor Marchant for his interest in the work and valuable advice.

THE LONDON POWER SCHEMES

UP to the present the views of the majority of the London Local Authorities towards the Companies' proposal embodied in their Parliamentary Bill are not known. In the case of St. Pancras, however, a report has been submitted to the Council by Mr. Sydney W. Baynes, their electrical engineer, in which he points out that St. Pancras would be included in the area scheduled, but it was not clear whether the Companies would compete for the Council's consumers. It appeared to be their intention, however, to supply private consumers for power purposes. At a later date the Company would be likely to obtain further powers to enable them to compete with the local authority. In any case, it was undesirable that the Company should possess powers over the St. Pancras area. Further, there was not sufficient provision in the Bill for the protection of the local authority as regards the breaking up of roads.

In the Preamble of the London and District Electricity Supply Bill there is a statement that the generation of energy is expensive because it is in the hands of a number of authorities and companies, and that it is expedient that electricity should be generated on a large scale in order that it may be used to a greater degree for industrial and other purposes. The results obtained at large stations recently, Mr. Baynes says, do not bear out these assertions. In the case of the Lots Road generating station (London Underground Electric Railways), he understood that the works costs were extraordinarily high for a station supplying so much power and with such an excellent load factor; and this new station might be taken as being well up-to-date. Section 52, sub-section 3, of the Bill provides that in the event of a local authority being authorised to supply in the area, the Company shall not supply power without the consent of the authorised distributor, provided the authorised distributor is willing to give a sufficient supply of energy at a price which the Company are supplying it, or are willing to supply it. Under this clause, Mr. Baynes protests, the Company would be in direct competition for all the Council's power consumers. They might easily bring the price down to an impossible figure and obtain the Council's power load. They might also acquire the lighting of power consumers' premises, as they propose that they should be permitted to supply lighting in any premises, together with the power supply, if the former load did not exceed 20 per cent. of the latter. It had been proved, however, that this 20 per cent. was sufficient to provide full lighting for most power consumers. The engineer further pointed out that under the Bill, whilst the Company supplying an authorised distributor were only liable to a penalty of £10 per day in default of supply, the authorised distributor would be liable to each individual consumer in the event of the Company failing to supply. There were other provisions which protected the Company in every way, and placed them in a much better position than that of the present authorised distributors. The engineer expressed the opinion that the Bills referred to should be opposed. This is to be done, and petitions will be presented against each of the schemes.

CATALOGUES AND PAMPHLETS RECEIVED

MOTORS WITH BALL BEARINGS.—A brochure from the Electric Construction Co. describes a new type of continuous-current motor fitted with ball bearings which the firm have introduced. It is claimed that, with this type of bearing, friction losses are almost eliminated. The bearings are liberally designed and fitted for heavy, continuous work, and their compactness facilitates efficient ventilation. In addition to this, constant replenishment of air (as in journal bearings) is not necessary, and the grease only needs replacement at intervals of four to six months.

SWITCHGEAR.—Messrs. Veritys have sent us a copy of a new abridged switchgear list in a convenient form, uniform with other small-sized lists previously issued. The publication is as condensed as possible, in order to cover extensive ground in a small space, and a useful feature is an index of catalogue numbers. Amongst novelties listed for the first time are a new pattern of heavy open protected fuse, a special street lighting switch, some new voltmeter switches and plugs, and some ornamental switchboard pediments in wrought iron.

ELECTRICAL MEASURING INSTRUMENTS AND SOME OF THEIR WEAKNESSES

IN a Paper read on Wednesday, January 8th, before the Association of Engineers-in-Charge, Mr. K. Edgcumbe said :—No apology is, I think, needed for admitting that electrical measuring instruments do possess some weaknesses.

I feel that if the ways of measuring instruments were rather better understood, and their little weak points more fully recognised, engineers would be spared many a *mauvais quart d'heure* with their meters, and the long-suffering instrument manufacturer would spend fewer sleepless nights.

A mistake is often made from the very outset in selecting the most suitable range when ordering the instrument; frequently the maximum possible emergency load which is likely to occur is selected, it being quite overlooked that for possibly nine-tenths of the time the load will not exceed a third of this value. The normal deflection is consequently so small that the accuracy is very much impaired. This is particularly unfortunate with moving iron instruments, since, owing to the fact that the permeability of iron is small at low inductions, the first tenth of the scale of such an iron instrument is always cramped. For this reason the top reading should be chosen as small as possible, so that the upper part of the scale may be mostly used.

In the case of moving coil instruments the scale is perfectly even throughout its range; but even then it is a great mistake to order a higher range than is absolutely necessary. For the same reason, if an instrument with several ranges is required for general testing work, each should be not more than five times that of the next lower in the case of a moving iron instrument, or more than ten times with a moving coil. In this connection it may be pointed out that it is always better, as far as possible, to make all the ranges round multiples of one another, so that one set of divisions can be used throughout, a constant of 2, 5, 10, &c., being applied according to the range.

This question of range becomes of supreme importance in ampere-hour or watt-hour meters, since with very light loads it is not simply a case of the indications being inaccurate, but the meters will not start at all below a certain minimum, owing to the initial friction which has to be overcome. An ampere-hour meter should start with from 1 per cent. to 1½ per cent. of its full load, and a watt-hour meter with from ¾ to 1 per cent.; but, unfortunately, after being installed for some time, it will often be found that these figures have to be doubled; consequently, it is better to so select the range of a meter that its maximum reading is, say, fifty times the smallest load, which it is wished to register, even if this entails overloading it to the extent of perhaps 20 per cent. or 30 per cent. for short periods.

In the case of alternating-current watt-meters, the power divided by the voltage does not necessarily give the amperes flowing. The current may be much greater than the value so obtained, according to the "power factor" of the circuit. Whenever possible, therefore, in ordering a watt-meter, not only the maximum reading in watts, kilowatts, or horse-power should be given, but also the corresponding current, or, failing this, the approximate power factor to be expected.

With voltmeters the requirements are different, the aim being, as a rule, to provide as open a scale as possible on either side of the normal working voltage; the rest of the range is unimportant, and may be closed up, or even suppressed altogether. This is easily done in one or two ways; in the case of moving iron voltmeters, the iron can be so shaped as to give the required scale, but with moving coil instruments it is only necessary to set up the control spring. By "set up" is meant, turning the outer end of the spring (that is, the end not attached to the pointer) back through a certain angle, so that when no current is flowing, the pointer is pressed hard against the left-hand end of the scale. Let it be assumed that the scale corresponds to a deflection of 90 degrees, and that the resistance is so proportioned that a full deflection from zero is given with 100 volts at the terminals. Then, if the free end of the spring is turned back through 90 degrees, it will require exactly 100 volts at the terminals of the instrument before the pointer begins to deflect, and 200 volts will take it to the end of the scale. Thus the length of each 1-volt division is now twice what it was before; if the spring had been set back through 180 degrees, it would have required 200 volts before it started reading, and 300 volts to take it to the top of the scale, and so on. It is, in fact, as though the instrument was provided with a very much longer scale, of which only the last 90 degrees were visible.

In practice several considerations prevent this setting up being pushed too far. In the first place, since the resistance remains unchanged in all three of the cases just considered, the watts lost with the 200-300 range are nine times as great as they were with the 0-100 scale, consequently, in order to reduce the power consumption to a reasonable value, a correspondingly weaker spring must be employed, which means an increased friction error. Again, with every spring there is a limiting angle through which it can safely be turned without strain; if deflected beyond this, an uncertainty of reading will be found. Neglect of this point is the cause of most of the wandering "zeros" in moving coil instruments.

All things considered, then, it may be said that a set-up corresponding to a scale of say 450-500 volts is about the greatest which can be regarded as satisfactory. In such an instrument the lower reading is 80 per cent. of the upper. A moving iron voltmeter scale reading up to 250 volts might contain 100-250 volts in the upper half, that is, roughly, 25 per cent. of the top reading. With an evenly divided moving coil scale, this would correspond to a total range of 125-250 volts. The smaller the percentage, the more open the scale; expressed in this way, it may be said that for a moving iron voltmeter, as ordinarily constructed, 25 per cent. is about the most open scale which it is advisable to provide, and for a moving coil instrument the corresponding figure would be 10 per cent.

For alternating-current central station work a voltmeter with an extraordinarily open scale has recently been introduced by one firm of instrument manufacturers, and with these instruments a scale such as 200-220 is quite satisfactorily obtained. It is, moreover, perfectly evenly divided throughout, and the power consumption is quite moderate. Such a scale would correspond to 5 per cent. of the top reading contained in the upper half.

A point requiring careful consideration when specifying an instrument is the accuracy to be aimed at.

One must remember that the accuracy of a test really depends on that of the least exact instrument used. For example, in testing the efficiency of a glow-lamp, it is sheer waste of time to measure the power consumption to 1 per cent., when the candle-power cannot be relied upon to within more than 5 per cent. In the case of a cell-testing voltmeter, on the other hand, an inaccuracy of more than 1 per cent. would be inadmissible.

A voltmeter, comprising, as it does, a copper coil, will have a resistance which varies with changes of temperature, yet it can only act correctly as a voltmeter so long as its resistance remains constant. In order to ensure this, as far as possible, an idle resistance is connected in series with the copper coil. The greater the proportion this "swamp" bears to the copper resistance, the less will be the variation of the reading with temperature. In order, however, to get the same working forces, the power consumption must be raised in proportion as the idle resistance is increased, since the watts lost in the latter are valueless as far as the working coil is concerned. The difference in reading when first put in circuit and after warming up, is quite negligible with moving coil meters, and may amount to 1 per cent. in the case of a moving iron instrument.

Of course, there are circumstances in which it is essential that the cold and hot readings should agree extremely closely, and in that case a slight increase in power consumption should be allowed. This seems to me to be just one of those cases in which nothing would be lost by consulting the instrument manufacturer as to the necessary conditions and the best means of meeting them.

The mistake often lies in the type of instrument selected for a particular purpose; for direct-current circuit the moving coil pattern is undoubtedly the one to choose. At the present time, owing to standardisation of patterns and so forth, the price of a moving coil instrument is only slightly higher than that of the moving iron type. For alternating current, on the other hand, the moving iron is greatly superior to the hot-wire or induction pattern on the score of both accuracy and durability. The former is always uncertain in its readings owing to the unequal expansion in the various parts, and the latter is seriously affected by frequency, wave form, and temperature. The moving iron pattern, if properly designed, is entirely free from these errors. Induction instruments have one advantage over others, viz., that a scale covering 300 degrees can readily be obtained. The fact is often overlooked, however, that this is no new innovation, and that moving coil instruments can be quite easily arranged to give such a scale; in fact, some of the earliest were so constructed, but the idea was abandoned in favour of a 90-degree scale for various reasons.

Digitized by Google

It may be asked what accuracies can be legitimately demanded in the case of the various forms of switchboard instrument. The following may perhaps serve as a rough guide :—Moving coil ammeter, 1 per cent. of the maximum scale reading. Moving coil voltmeter, ½ per cent. of the maximum scale reading in the neighbourhood of the normal point. Moving iron ammeter, alternating current, 1 per cent.; direct current, 2 per cent. of the maximum scale reading. Moving iron voltmeter, alternating current, ½ per cent.; direct current, 1 per cent. of the maximum scale reading in the neighbourhood of the normal point. Induction ammeter, 2½ per cent. of the maximum scale reading. Induction voltmeter, 2 per cent. of the maximum scale reading. Induction wattmeter, 3 per cent. of the maximum scale reading. Hot-wire ammeter or voltmeter, 2 per cent. of the maximum scale reading. Electrostatic voltmeter (low tension), 1 per cent. of the maximum scale reading. Electrostatic voltmeter (high tension), 2 per cent. of the maximum scale reading. Dynamometer wattmeter, 2 per cent. of the maximum scale reading. Recording ammeters and voltmeters (pen type), 2½ per cent. of the maximum scale reading. Recording ammeters and voltmeters (inkless type), 1½ per cent. of the maximum scale reading. Ampere-hour meters, one-fifth load to 20 per cent. overload, 3 per cent. Watt-hour meters, one-tenth load to 20 per cent. overload, 2½ per cent.

Accuracy, however, by itself is of little use; several other features have to be taken into account. For example, if the instrument has to be seen from a distance, the scale should be open and the pointer and figures bold. If the case is of cast-iron with a semi-closed front (a pattern, by the way, which is much more satisfactory all round than the once popular brass case), the opening through which the pointer and dial are seen should be fairly large.

An electrical measuring instrument is a somewhat delicate apparatus, and must be treated with a little care.

It is always best to remove the instruments from the switchboard and pack them separately, when sending by rail. Care should be taken that dangerous shocks are not transmitted to the jewels and pivots through excessive vibration on the switchboard after erection. When vibration cannot be avoided, rubber washers inserted between the instrument and the slate will, to a large extent, get over the trouble.

Before removal from a switchboard, it should be noticed whether there is any clamping arrangement for the pointer or armature, and if so, this must be seen to. Any liquid also, such as oil or mercury, must be carefully removed, or the instrument will be ruined. Before switching on the current it must be seen that all the pointers are accurately at zero; if spring controlled, by adjusting the spring; if gravity controlled, by setting round the whole instrument. A very small zero error may make a considerable difference in the reading, so that care should be taken that the adjustment is accurate, the instrument being gently tapped meanwhile to eliminate any possible friction. In the case of shunted ammeters, the length of the connecting leads should not be much altered, since the instrument has doubtless been calibrated to them. If too long, they can usually be neatly coiled up out of the way; and, if too short, new leads of correspondingly increased area should be employed so as to keep the resistance approximately the same. In the case of voltmeters, this precaution is unnecessary, owing to the much greater resistance of the instrument. If a shunt is found to get too hot when only the normal maximum current is passing, it is probable that there is a bad contact at one or other end, due to a dirty cable socket or to a bolt having worked loose; or it may be that the leads bringing the current to it are too small in area, so that the heating comes from them. When an instrument works erratically, the reading fluctuating with a steady load, the connections should be seen to. If a voltmeter takes to reading too high, there is a short circuit in the series resistance; if too low, in the coil itself. If an integrating meter will not start with so low a load as usual, it is probably the brushes and commutator which are at fault, and the latter should be carefully cleaned. If, on the other hand, a watt-hour meter starts without any current flowing through the series coil—that is, if it "runs on its shunt," as it is called—it is a sign that the starting coil is too close up. The starting coil is a winding in series with the armature, and is provided to overcome friction. It is easily adjustable, and should be pulled further away. In an induction watt-hour meter the starting device usually takes the form of an aluminium plate, which can be moved slightly in one direction or the other. To make an integrating meter run slower, the break magnet should be moved towards the periphery of the disc, and *vice versa*.

Now that the introduction of some new type of incandescent lamp is a matter of almost daily occurrence, it becomes of the utmost importance to be able to determine the efficiency and general behaviour of the various lamps. Few of us are so fortunate as to possess an elaborately equipped photometer room, yet the equipment needed for what may be called "commercial" lamp testing is extremely simple.

The most satisfactory photometer consists of two cards inclined at an agle, each illuminated by one of the lights and so placed that one card is seen behind the sharply cut edge of the other. A glow-lamp whose candle-power at the normal voltage is known, forms the standard, and is set at a given distance on one side of the cards. Another lamp—the candle-power of which is immaterial—is placed on the other side, and is moved to and fro until the two cards appear to be equally illuminated, after which this lamp must not be again moved. The standard lamp is now replaced by the lamp to be tested, which is in its turn moved up to and away from the photometer until a balance of illumination has again been obtained. This is the method in its crudest form; several small refinements and modifications are possible.

In order to be able to determine the efficiency of a lamp, the consumption must be measured, and for this purpose a dead-beat ammeter or wattmeter, provided with a lamp-holder, is the most suitable. The instrument should also be furnished with a fine wire fuse, and even when so protected, it is best to temporarily short-circuit the ammeter when the lamp is first put into circuit, in order to prevent any damage in the event of a faulty lamp being put into the holder

A brief discussion followed the reading of the paper.

ELECTRICAL SCIENCE

British and American

An Electrical Thermometer for Measuring Gas-Engine Temperatures.—H. L. Callendar and W. E. Dalby describe in the Royal Society *Proceedings* for December a form of platinum thermometer which measures directly the temperature of the gas in the cylinder of a gas-engine at some one point of the cycle. In order to avoid uncertain corrections, it is necessary in any attempt on this problem to employ wires fine enough to follow the changes of temperature of the gas very closely during suction and compression. If such a wire be employed under working conditions, it must be perfectly screened from the flame during explosion. The arrangement designed by the authors is such as to introduce the thermometer into, and withdraw it from, the cylinder at the proper instants, and to do this without making any change in the usual form and extent of the clearance surface during the time interval comprising the end of compression. The thermometer itself consisted of a loop of platinum wire 0·001 inch diameter and 1 inch long, and a compensation loop of similar wire was provided to eliminate the end effects arising from conduction to the leads. The current employed in measuring the change of resistance (which was about 1 ohm for 100° C. rise) was about $\frac{1}{250}$ ampere. This thermometric arrangement was contained in a small valve inserted through the spindle of the admission valve, which was bored out to receive it. This thermometer valve was introduced into the cylinder by a cam operated by a simple gear. In order to measure the temperature at a definite point of the cycle, a periodic contact-maker was inserted in the testing battery circuit. At first an ordinary wiping contact was employed, but, owing to certain disadvantages, a novel form of periodic contact was designed and made. This consisted of two cams on the same axle and two brushes. The shape of each cam was a flat spiral, which lifted the corresponding springy brush away from the axis as the shaft rotated, and the spirals each terminated with a step which allowed the brushes to fall suddenly. The steps were staggered in angle, so that the brushes fell at different instants. Now one side of the electrical contact was carried by one brush, and the other side of the contact by a projection on the second brush; and thus, by setting the cams initially at the proper angle, any desired period of contact could be brought about at any desired point of the gas-engine cycle.

Properties of Selenium.—It is well known that the increase in conductivity of selenium which results from illumination is not an instantaneous effect, and that the recovery of normal conductivity takes time. In the December *Physical Review* is a note in which E. Merritt gives the results of his measurements of the relation between conductivity and time after cessation of exposure to light. The cell used had a resistance of about 50,000 ohms. It was placed in a circuit containing a dead-heat galvanometer and an E.M.F. of about 1 volt, and was excited by an acetylene flame at a distance of 40 cm. The author, guided by his experience of a similar study of the decay of

Digitized by Google

phosphorescence in Sidot blende, plotted his results by taking as ordinates the square root of the difference between actual conductivity at any time and the normal conductivity, the abscissæ being the times of observation. The curves so obtained are seen to consist of two straight parts joined by a "knee" at about abscissa ten seconds. It seems not unlikely that the bend at the "knee" in the early stages of the decay of the photo-induced conductivity may be due to the fact that the exciting rays penetrate only a short distance below the surface. The surface layer is, in consequence, excited far more strongly than the interior, and decays with corresponding rapidity. After a short time the conditions will be more nearly uniform throughout, and the decay will be more gradual. The author believes that if experiments could be made with a sufficiently thin layer, the curves would be straight lines throughout.

Continental

Fixation of Nitrogen.—A summary of the present state of the problem of fixing atmospheric nitrogen is given by J. Blondin in *Bulletin* No. 269 of the French Physical Society. Of the four chief processes hitherto proposed, three utilise electric energy direct. The fourth, that of Frank and Caro, obtains calcium cyanamide from the carbide, itself an electrical product. The other processes use the electric arc, in which the process takes place according to the simple formula $N+O=NO$. Nernst's discovery that an increase of temperature from 1,811° to 3,200° absolute increases the yield fifteen times has been turned to account in the process carried out by Kowalski and Moscicki at Vevey, where frequencies as high as 8,000 and 12,000 are used. The large number of condensers used in this process has been reduced by Moscicki's recent device of rotating the arc by means of a magnetic field. The voltage used is 3,000, and the yield is said to be 60 grammes of nitric acid per kw.-hour. But this process is not yet carried out on an industrial scale. The Norwegian works of Birkeland and Eyde at Notodden also use a magnetic field, and claim to produce 500 kgr. per kw.-year, or 17,000 tons annually. The cost comes to something like a shilling per kg. of nitrogen fixed.

Electrolytic Reduction of Indigo.—Indigo has hitherto been reduced from the blue to the white form by fermentation or by chemical processes. In the *Comptes Rendus* for December 30th, however, H. Chaumat describes an electrical method in which the reduction is accomplished by bringing nascent hydrogen to bear upon the substance as it is evolved at the cathode of a cell containing sodium carbonate in solution. Blue indigo contained in such a cell is not reduced, most likely because the hydrogen passes too rapidly into the molecular state. The author, therefore, took care that the hydrogen was evolved on the iodine itself by mixing it intimately with carbon and piling it about the cathode, dividing off the anode by means of a porous diaphragm. The mixture of graphite and indigo is tied round with a linen bag. The reduction of the indigo gives a highly concentrated solution of white indigo, the efficiency of the current being as high as 30 or 40 per cent. The porous diaphragm is necessary to prevent the oxygen evolved from re-oxidising the indigo. Alkaline sulphites or sulphides may be employed for the same purpose, but with a loss of quantity produced.

Radioactive Substances in the Atmosphere.—K. Kurz, in No. 15 of the *Annalen der Physik*, calls attention to the errors in readings of atmospheric ionisation produced by the deposition of the solid radioactive matter suspended in the air upon the measuring instruments. When gold-leaf electroscopes are used with a charged dissipation body, a disturbing effect is only produced when the body is negatively charged. The deposition of radioactive matter then produces an effect simulating the presence of a greater number of positive ions. In Ebert's aspiration apparatus the number of ions is made some 4 per cent. too great, and their velocity 4 per cent. too small. If, instead of working with a saturation current, the instruments were to work with a free current, these errors would be eliminated. The author has made the necessary corrections on the various instruments, and has found the very simple relation that positive and negative ions supply the same conductivity to the atmosphere. Since the positive ions are less mobile, they must be present in greater proportion. This state of things is automatically regulated by the adsorption of ions at the surfaces of dust and smoke particles, which is proportional to their mobility. The saturation current at Giessen is $7{\cdot}16\times10^{-5}$ electrostatic units.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

IN the *Centralblatt für Accumulatoren und Galvanotechnik* of January 5th there is an article entitled "Some Novelties in Plating Baths." Owing to nickel anodes not passing into solution at the same rate as the nickel is deposited out upon the cathodes, nickel plating baths in course of time become acid. The acidity is usually got rid of by addition of ammonia, but this has the disadvantage of saturating the electrolyte with ammonium sulphate, which after a time commences to crystallise out, rendering it necessary to renew the bath. It is now suggested that nickel carbonate should be added to the bath to neutralise the acid. The nickel carbonate should be freshly precipitated, and is best added in the form of a paste. An excess of the nickel carbonate does not interfere, as it simply remains in the bath and neutralises the acid as it is formed, and the concentration of the nickel in the bath remains constant. On the other hand, an excess of ammonia is harmful, as it causes the deposited metal to be brittle, and it does not then adhere so well.

When articles are plated with an alloy of silver and nickel, the appearance is more brilliant, and is harder and also cheaper than when pure silver is employed. R. H. Marshall gives the following receipt for preparing the bath:—1 kilogram each of the double-cyanide of nickel and silver is dissolved in 100 litres of water and electrolysed, using an anode of pure silver. From time to time extra potassium nickel cyanide is added to the bath to take the place of the deposited nickel.

Metallic deposits, which are sometimes difficult to obtain in a dense and coherent form, will, according to A. Classen, be deposited in a dense, brilliant, and homogeneous condition by adding to the bath some glucoside such as the decoction obtained by steeping liquorice root in water, or, according to L. Trunkhahn, a mixture of syrup and a ferment such as yeast. Thus, for example, 20 kilog. of zinc sulphate, 1 kilog. of zinc chloride, 4 kilog. sodium sulphate, 0·5 kilog. of boric acid, and then 5 kilog. of liquorice decoction, are added to 100 kilog. water. Or, 25 kilog. zinc sulphate, 15 kilog. aluminium sulphate, 1 kilog. chalk, 4 kilog. glucose, and 0·5 kilog. yeast. In both these cases information as to the anode employed would be of interest. If in the second case an insoluble anode is employed, then the calcium carbonate might very well be replaced by zinc carbonate or oxide.

According to J. Schiele, if iron is to be plated with silver or gold, it should be first coated with a thin layer of tin-aluminium-magnesium alloy, and the following method is recommended. In 9 litres of water dissolve 500 gm. sodium pyrophosphate and 100 gm. tin chloride; add to this solution 1 litre of a solution containing 50 gm. aluminium nitrate and 50 gm. magnesium. Use as anodes tin and aluminium sheets. Such a solution with such electrodes would not, as a matter of fact, deposit an alloy of tin-aluminium and magnesium. In the first place, the tin anode alone would function, because it is well known that aluminium anodes will not after a few seconds allow the passage of the current—hence rectifying action with alternating currents. Secondly, neither aluminium nor magnesium are deposited from aqueous solutions.

E. L. Lecoq recommends the following bath for depositing brass upon steel, cast-iron, or wrought-iron. In 100 litres of water dissolve 3 kilog. sodium carbonate, 4 kilog. sodium sulphate, 6·5 gm. potassium cyanide, 2·25 kilog. copper acetate, 1·1 kilog. zinc sulphate, 0·1 kilog. tin chloride, 0·1 kilog. lead acetate, 0·25 kilog. zinc chloride, and then add 2 litres of ammonia. Whether anodes of brass or of copper and zinc should be employed is not mentioned. Further, one is rather inclined to ask which of these numerous ingredients could be left out without hurting the results.

Celluloid is often used in accumulators to prevent contact between the negative and positive plates. It is therefore of interest to notice that F. Schoenbeck finds that when cuttings of celluloid are put in a closed flask with accumulator sulphuric acid and allowed to stand for some months, the acid at the end of the time shows reactions for nitric acid. Under working conditions this would probably be reduced to ammonia, which is always considered to be harmful to accumulators.

E. F. Kern and H. S. Auerbach describe a series of experiments on the cathodic reduction of artificially prepared lead sulphide with different fused electrolytes (*Society of Chemical Industry*, December 31st, 1907). In each case the lead sulphide was crushed to about 30-mesh size, and placed on the surface of a molten lead cathode, in a clay crucible with chloride electrolytes or graphite crucible with fluoride electrolytes. Pieces of Acheson graphite were employed as anodes. Alkali chlorides or calcium chloride were found to act satisfactorily as electrolytes. With the former the E.M.F. is about 5 volts lower than with the latter, but calcium chloride gives a more fluid bath, and is less readily volatilised. With a mixture of cryolite and fluor-spar as electrolyte, a higher current efficiency is obtained, but the bath is apt to become viscid. With chloride electrolytes, chlorine is evolved at the commencement of the electrolysis, but as the electrolysis proceeds, and sulphides begin to be formed by the reduction of the lead sulphide, then chlorine ceases to be liberated, because the critical voltage of the sulphides is lower than that of the chlorides. Finally, sulphur commences to separate at the anode, and may be collected or allowed to burn away. When chloride electrolytes are employed the current efficiency increases with the temperature. In some experiments in which natural galena was used and an electrolyte of calcium chloride, the current efficiency was at first very low; but when the reaction-product was re-melted underneath calcium chloride and the mixture heated to 1,200°, the calcium which had alloyed with the fused lead was liberated, and then reduced a further quantity of galena which was floating upon its surface, the current efficiency being increased from 26·5 per cent. to 43 per cent.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Jan. 9th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

1906 Patents

23,009, B. T. H. Co. & DALTON. This relates to improvements in electric arc lamps of the converging carbon or the parallel electrode type. A downward feed controlling mechanism is used, consisting of a slider hung on a flexible suspension for the electrodes, between the ends of the suspension and a clutch, one of the members of which is carried by the slider to control its movement. In another form of controlling mechanism the clutch is shaped like a nut, having an angular-shaped aperture, through which an angular twisted rod passes, which is untwisted by the regulating mechanism, allowing the movement of the slider to permit a downward feed of the electrodes. Three claims, two figures.

27,520. KANDO. This relates to the control of groups of polyphase electric traction motors, in which the current taken by the motor or group of motors first reaching full speed is arranged to control the rheostats governing the remaining motors or groups of motors in such a manner that the latter are prevented from taking more current than the first-mentioned motor or group of motors. A rheostat having a transformer, the primary winding of which is connected in one or more of the phase circuits of the motor, and the secondary winding is connected in the circuit of the regulating magnets of all the rheostats of the system, each of the transformers being arranged to be inoperative except when the secondary winding of its corresponding motor or group of motors is short-circuited. The voltage can be regulated by hand for controlling the operation of the rheostats of all the motors or groups of motors until they reach full speed. Four claims, two figures.

1907 Patents

3,078. C. G. NOBBS and C. G. NOBBS, Jun. This specification relates to an electric steam radiator, in which resistance coils are inserted in the bottom chamber of the radiator. The coils may be of iron wire or other suitable material, immersed in a quantity of water, which may be very small in volume compared with the capacity of the radiator. The coil may be placed in the receptacle or bottom of the radiator, which is connected to it by pipe coils. The radiators may also be provided with coils for superheating the steam, if necessary. The radiators may work singly or in series with one another, and thus do away with steam piping round the buildings. Suitable switches are provided for cutting out one or more heating elements as required. Four claims, one figure.

3,214, G. HOOKHAM, W. S. SPRAGUE, relates to improvements in the counting trains of electricity meters, by which the counting train is driven in such a manner that there will be no sudden resistance offered to the rotation of the driving spindle, while at the same time there is no uncertainty as to the correct reading at any time. The first disc is driven through a spring which causes the disc to remain fixed just before it is desired to operate the train, while the continued revolution of the driving spindle puts the spring in tension, and at a predetermined position in its revolution releases the disc, causing the spring to operate the next disc of the train. Three claims, three figures.

4,801, POULSEN. This relates to receivers for wireless signalling by electro-magnetic waves, so that the receiving vibration circuit is periodically brought out of resonance without opening the circuit itself, and the circuit transforms energy from space, and has the wave indicator connected to it, so that the energy accumulated by resonance is brought to discharge itself suddenly through the wave indicator. Two figures.

10,369. ATELIERS THOMSON-HOUSTON. This relates to improvements in the commutation of dynamo electric machines, and the object is to avoid unequal distribution of current in the different circuits of a parallel armature winding due to non-symmetry in the flux; or in the value of the contact resistances of the brushes. This is done by exciting the supplementary poles by the aid of ampere turns, which are a function of the current which flows through the different conductors which they influence. This relates particularly to drum-wound machines with their windings in parallel, each pole is excited from two coils connected to brushes of opposite polarity, and so arranged that the coils on adjacent poles are in series with each other and one of the brushes. Each supplementary pole is then excited by the aid of two coils, respectively in series with two different lines of brushes, and upon two supplementary poles there are two coils in series with one line of brushes. These coils are placed in different circuits, connecting the brush holders to the system serving to put the brushes in parallel. Three claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

20,928, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Operating electric motors for braking purposes.
21,504, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Manufacture of electric conductors of refractory metal, especially for electric lamps.
23,894, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric motor control systems and apparatus.
23,944, HIRST & GUNNER. Electrical conduit and junction-box.
26,644, LEITNER. Electric supply systems.
29,174, LEITNER. Electric motors.
29,320, LUBECK. Electric switch.
29,584, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Circuit-controlling mechanism.
29,618, SCIPLE. Sectional poles for telephone, telegraph, &c.
29,639. SCOTT. Electric circuit breakers.
29,639B, SCOTT. Electric circuit breakers or switches.
29,655, RUTHENBURG. Electrolytic apparatus.
29,665, DAWSON & BUCKHAM. Electrical signalling apparatus.
29,758, LEITNER. Systems of electric train lighting.

1907 Patents

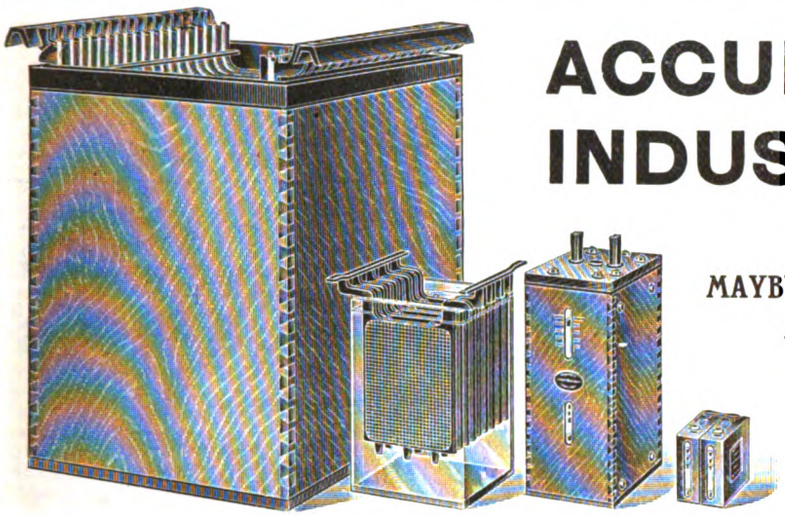
795, KILROY, & EVERSHED & VIGNOLES, LTD. Automatic electric motor starter.
836, SMITH-SAVILLE. Portable tram rail grinding machines.
1,685, COUADE. Electric service motors.
2,029, HEWETT & FOSTER. Electrical advertising devices.
2,959, PURVES & SINNOTT. Electrical insulators for telegraph or telephone wires or the like.
2,973, LOWTHIAN. Electro-mechanical fog signals for railways.
3,212, TIERCELIN. Locks and electrical switches.
3,613, GUNNING. Automatic periodically-operated switches.
3,908, SUNDERLAND FORGE AND ENGINEERING CO. & BLAIR. Electric cranes, winches, and the like.
3,997, ELECTRIC IGNITION CO. & HALL. Dynamo-electric ignition apparatus of internal-combustion engines.
6,134, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Signalling systems for railways and the like.
7,065, ULLRICH. Coin-freed mechanism for electricity meters.
8,173A, MILTON. Inductor alternators.
8,462, MARCONI & MARCONI'S WIRELESS TELEGRAPH CO. Apparatus for wireless telegraphy.
8,463, MARCONI & MARCONI'S WIRELESS TELEGRAPH CO. Apparatus for wireless telegraphy
8,623, STONE & MIGOTTI. Means of propulsion of electrically driven trains and the like.
10,259, LE TALL (*Hewitt*). Wireless telegraphy.
17,707, HUNTER & WARREN. Electric switches.
21,842, KELLOND. Adjustable electric lamp-shade holder.

The following complete Specifications are open to Public Inspection at the Patent Office, but are not yet published for sale.

1907 Patents

12,635, GALLETTI. Wireless telegraphy.
26,530, GES. FÜR DRAHTLOSE TELEGRAPHIE. Radio-telephony.
26,622, CUMONT & COMPAGNIE DE SIGNAUX ELECTRIQUES POUR CHEMINS DE FER. Railway signal and point mechanism.
27,672, PIEPER. Driving of electric cranes and the like.
27,739, JANECEK. Arc lamp with a support electrode with which the other electrode is rigidly connected.
27,825, FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. Electric igniters for internal-combustion engines.
28,138, ALLGEMEINE ELEKTRICITÄTS-GES. Electric lamps.
28,220, THOMAS. Starting means for vapour electric devices.

Expiring Patents



The following patents expire during the current week, after a life of fourteen years:

1,087, THWAITES & CAWLEY. January 20th, 1897. This describes a well-known system of haulage on canals or waterways, in which a motor is suspended from an overhead rail, and tows the vessel along the waterway.

1,417, January 23rd, 1894. G. H. WHITTINGHAM. This relates to an automatic device for removing resistance in starting electric motors, and replacing it again, its object being to gradually reduce the resistance in the armature circuit automatically, and replace the resistance when the current is shut off the motor.

LOCAL NOTES

AUSTRALIA: *Adelaide Tramways.*—The Adelaide Electric Supply Co. have entered into an arrangement to supply the Adelaide Tramways with power, pending the erection of the Tramways Power House, at Port Adelaide. The present generators at the Greenfell Station of the Supply Co. will be ample for the purpose for some time to come. The Supply Co. have ordered two new turbine generators, each of 1200 h.p., and one of these is to be used solely for the tramway work. Extensive alterations are now being made at the works, and the capacity of the station when the new sets are installed will be 5,000 h.p. The Tramways Trust hope to have the service in North Adelaide running before Christmas, 1908.

BARNES: *Proposed Tramways.*—At a general meeting of the Barnes and Mortlake Ratepayers' Association, held on Tuesday night of last week, the following resolution was carried unanimously :—"That the Barnes and Mortlake Ratepayers' Association, having held a public meeting with a view of ascertaining the wishes of the ratepayers on the tramways question, hereby urges the Urban District Council to oppose any Bill now before Parliament."

BELFAST: *Cavehill and Whitewell Tramways.*—A meeting of the ratepayers, convened by the Lord Mayor, was held in the Council Chamber at the City Hall, on January 7th, for the purpose of confirming the Council's resolution to promote the Belfast Corporation (Tramways) Bill. There was a big attendance of ratepayers present. The proposal was not favourably viewed by the ratepayers, who considered that the sum of £20,000, which it was proposed to pay for goodwill, was absolutely wasted, as the whole undertaking was only earning £4,500 a year, and they also objected to paying £60,000 for what was said to be practically a bankrupt concern. An amendment was proposed for taking a plebiscite to decide whether the Council should proceed with the Bill, and was carried.

BOLTON: *Electricity Station Matters.*—At a meeting of the Electricity Committee, held on Thursday, January 9th, it was announced that the Markets Committee had agreed to purchase the motors on hire at the Cold Stores.—A letter was read from the British Westinghouse Electrical Manufacturing Co., pointing out that a negative booster in use at their electricity works was an infringement of their patent rights. The matter was referred to the Chairman, Vice-Chairman, Town Clerk, and the Electrical Engineer.—As a result of an overwhelming vote of ratepayers, assembled in the Albert Hall on Tuesday evening, January 7th, against the proposal of the Town Council to construct tramways in Deans Lane, the Bill promoted in Parliament by the Corporation in relation to that work will now be dropped.

BOURNEMOUTH: *Assessment Cases.*—The Corporation of Bournemouth have appealed to the Quarter Sessions against the assessment of poor rate on the light railways within the Borough of Poole. The case came before the Recorder of Poole (Mr. Clavell Salter, K.C.). The appellants urged that they were not free agents when the agreement was made to take over the tramways. The effect of the agreement was to say that the tenants were holding property on certain very onerous terms, which affected the tenant in his relations to the public. The tenant was to run cars with certain specified services and fares on Sundays, so as to accommodate the public. Several valuers had made their valuation, but none had placed it upon the rent. The valuation was based, as far as possible, on the receipts per car mile. The rateable value was made out to be between £2,000 and £3,000. The Recorder, in giving judgment, said he thought the correct method was to proceed upon the estimated gross receipts and expenses per car mile in the parish of Poole, without regard to the rest of the system, and he came to the conclusion that this property might fairly be expected to let in the conditions prescribed by statute for a rent which would justify the rating appealed from, and therefore the appeal must fail. The appeal was dismissed, with costs.

BRENTFORD: *Kew Bridge Tramways.*—The District Council has decided not to oppose the Bill promoted by the London United Tramway Co., which seeks powers to cross Kew Bridge.

BURSLEM: *The Supply of Electricity Bill.*—The Electric Lighting Committee have resolved to ask the Board of Trade to re-introduce the Supply of Electricity Bill during the coming session of Parliament, and to take every means to have the same passed into law. A copy of the resolution was ordered to be sent to the local Members of Parliament and the Secretary of the Board of Trade.

BURTON-ON-TRENT: *Electricity Returns.*—The advantages of supplying power on the restricted hour principle, i.e., the restriction of the demand during the hours of the winter peak loads, has been shown at Burton. Taking the last three years for the periods of April 1st to the end of December :—Lighting and power units, 1905, 259,508; 1906, 382,318; 1907, 550,529. Motors connected in the above periods, kw. :—1905, 4·5; 1906, 128; 1907, 233. Lighting connected in kw. :—1905, 48.25; 1906, 35; 1907, 37. Total extra kw. connected :—52·75, 163, 270, for the three years. Maximum load in kw. : (1) 492 kw.; (2) 511 kw.; (3) 515 kw. The percentage increase in units was 47·4 per cent. in 1906, and 44 per cent. in 1907. From these figures it will be noticed that 112 per cent. more units have been sent out in 1907 than 1905, and only a 4·68 per cent. increase of the maximum load, and 433 kw. more was connected in 1907.

CARMARTHEN: *Electric Lighting Provisional Order.*—A special meeting of the Carmarthen Town Council was held on Friday to consider the draft arrangement with Messrs. J. B. Saunders & Co., of Cardiff, for the electric lighting of the town. Several objections were made on the ground that the electricians had not adhered strictly to the terms contained in the agreement entered into with the Council some time ago. Chief objection was laid to Clause 12 in regard to overhead wires, the Clerk (Mr. R. M. Thomas) being instructed to lodge an objection with the Board of Trade by the 15th inst., in case Messrs. Saunders & Co. did not acquiesce in the Council's demands.

CHISWICK: *Noisy Tramcars.*—The Works Committee of the Council, on January 9th, decided to support Ealing's application for an injunction against the London United Tramways Company on account of the noise occasioned by tramcars, and contribute £60 towards the cost. A resolution was also carried to call the attention of the Commissioner of Police to the noise of the trams, and request him to withdraw his licence in respect of those cars found to be unsuitable.

EALING: *Proposed New Tramways.*—At the last meeting of the District Council, Mr. Armriding, at the suggestion of the Mayor, moved that a joint committee consider the feasibility and expediency of providing a system of electric tramways or motor 'buses from the southern and south-western part of the borough to the main roads. General agreement with the proposal as regards tramways was expressed, but objection was taken to the portion of the motion regarding motor 'buses. The resolution was agree to.

KINGSWOOD: *Electric Supply Order.*—A communication has been received from the Board of Trade to the effect that they had decided to defer revoking the Order granted the Kingswood Electric Supply Company until May 1st.

LIVERPOOL: *Tramways Record.*—At a meeting of the Liverpool Corporation Electric Tramways Committee it was reported that last year's traffic as regards receipts, passengers carried, and earnings per car mile, was the greatest recorded. The passengers numbered over 124,000,000, nearly a million more than in the previous twelve months. The receipts were nearly £572,000, an increase of over £8,000; and the car mileage was over 12,200,000, an increase of nearly 116,000. The average earnings per car mile were 11·22d., an increase of 0·05d.

LONDON: *Camberwell:* Deputation to the Board of Trade.—A deputation from the Borough Council waited upon Mr. Hudson Kearley, M.P., and the Hon. T. H. W. Pelham, at the offices of the Board of Trade recently, with regard to the accounts and audit of the County of London Electric Supply Co., Ltd. The deputation pointed out that the Board of Trade admitted that the company's order constituted a separate and distinct undertaking within the Camberwell area, and therefore that the Borough Council were entitled to demand that accounts and information should be submitted in respect of the Camberwell area alone. Of the various forms of accounts the Board of Trade required electric lighting companies to prepare, the company had merely returned two—the capital account and the revenue account. The revenue account for 1906 showed a balance of £10,032 14s. 5d. This balance should be carried to the net revenue account. It should there be operated upon by means of transfers, a portion being allocated to reserve fund account, and another portion to depreciation fund account. According to the published accounts, the Camberwell profit balances appeared to have been merged in the general accounts of the whole of the company's business. In passing, the deputation suggested that the position of the reserve fund and the depreciation fund, from the commencement of the undertaking to the present time, ought to be disclosed, since the company year by year abstracted the cost of repairs and renewals from the Camberwell revenue accounts—thereby increasing the apparent profits—and placed this expenditure to the debit of the general depreciation fund, which would accordingly appear to be replenished in part by transfers from the Camberwell profit balances. Bearing in mind that on the construction of the Camberwell purchase clause the question of the sufficiency or insufficiency of dividends earned, as compared with the dividend of 5 per cent., referred to in the Camberwell Electric Lighting Order, would play an important part in determining the purchase price of the undertaking if sold to the Borough Council, the deputation considered it was essential that the Camberwell revenue accounts should be supplemented by net revenue, reserve fund, and depreciation fund accounts. The statement of electricity generated and sold—at present withheld—would give the Borough Council important information which would seriously influence any decision as to exercising powers of purchase, as it included data showing the proportions to the total quantities of electricity generated and distributed; of the quantities sold for lighting and for power purposes respectively. Mr. Kearley promised that he would carefully consider the points raised, and also whether the Board of Trade should exercise their

Digitized by Google

wheel, &c., for the water and lighting scheme of Matatiele, Cape Colony (municipality); electrical equipment at the Bluff, the Point (Durban), and the Maritzburg Railway workshops (Natal Agent-General, London); telephone and other electric plant at the Roodepoort Post Office (Transvaal Agent-General, London).

SPAIN.—An American Consular report states that a royal order has been published in the Spanish *Official Gazette*, inviting tenders from native firms for the installation of a telephone system connecting with the French wires at the frontier towns of Irun and Portbou, the details being as follows:—The line will start from Madrid, and at Zaragoza branch off in two directions, one passing through Pamplona, Tolosa, and San Sebastian to Irun, and the other following the line through Lerida to Barcelona and Tarragona, and thence on through Gerona to Portbou on the French frontier, thus establishing communication between Barcelona and France. Tenders are also solicited for the construction and working of telephone systems connecting Madrid with Coruna and Ferrol, with Pontevedra by way of Orense and Vigo, on to Gijon, Santander, and several other smaller towns. This will be known as the North-western System. Another, the South-eastern System, will connect Madrid with Cartagena, Albacete, Alicante, and Murcia, Almeria, Lorca, Linares, Jaen, Granada, Baza, and Motril. Another system, to be known as the Southern Telephone System, will link up Madrid with Cadiz, passing through Ciudad Real, Almaden, Cordova, Seville, and Jerez; with Malaga, by way of Bobadilla, and with Huelva, Caceres, Badajoz, and Zafra. Inasmuch as only native firms are invited to compete for these contracts, their interest for exporters, it is pointed out, lies in the fact that large orders will naturally be given by contractors for wire, posts, insulators, and other material as soon as the contracts are finally signed, which it is expected will be in January next.

TURKEY.—The Turkish Minister of Public Works has received an application for a concession for the erection of an electric lighting and traction undertaking at Monastir. The applicant is Mustafa Shukri Bey, Vice-President of the Chamber of Commerce. It is also announced that Giovanni Passizzi and Ludovico Galeotti have applied to the Smyrna municipality for a concession for the electric lighting of the town.

WIMBLEDON.—The Corporation invite tenders for the supply and erection of the undermentioned plant at their electricity works, and are prepared to accept tenders subject to the sanction of the Local Government Board being obtained for the necessary loan:—(*a*) A 1,000 kw. turbo-alternator, with condensing plant; (*b*) two water-tube boilers, economisers, pipe-work, and feed pump; (*c*) high-tension main switchboard and switchboard gallery. Forms of specification and tender, with the general conditions, may be obtained from Mr. H. Tomlinson-Lee, the Borough Electrical Engineer, Electricity Works, Durnsford Road, Wimbledon (fee £1 each specification, returnable), and tenders to the Town Clerk by February 18th.

YARMOUTH.—Tenders are invited for the supply, delivery, and erection of a 400 kw. continuous-current traction generator. Particulars and forms of tender from the Borough Electrical Engineer, 20 King Street, Great Yarmouth (fee £1 1s., returnable), to whom tenders by February 1st.

TENDERS RECEIVED AND ACCEPTED

ABERDEEN.—With reference to the recent tender accepted for the supply of fittings for the street electric lamps, it has been remitted to the Lighting & Fires Committee to submit a report to the Council giving full particulars as to the prices charged under the new contract, compared with the prices formerly paid to the electricity department for the same articles together with the specification submitted to the contractors.

AUSTRALIA.—The Victorian Postmaster-General's department has accepted the tender of Messrs. J. Bartram & Son, Melbourne, for the supply and delivery of eleven sections of branching system magneto-telephone switchboard.

BURY.—The following contracts have been entered into for the year by the Tramways Committee:—Brake blocks, F. R. Cass (Bury); hire of ticket-punches, Bell Punch & Printing Co. (London); tickets, J. R. Williams & Co. (Liverpool); uniform clothing, H. Lotery & Co. (London).

CARDIFF.—The Electrical and Tramways Committee has accepted the tenders of the British Westinghouse Co. for two transformers for supplying the Great Western Railway Co.'s passenger stations with electric light—one of 50 kw at £53 10s., and one of 40 kw. at £47. These tenders were the lowest.

LANCASHIRE.—Messrs. Bruce Peebles & Co., Ltd., have received from the Ray Mills Co., Ltd., an order for the complete electrical equipment of their spinning mill at Stalybridge.

LONDON.—The Kensington and Notting Hill Electric Lighting Companies Joint Works, Wood Lane, Shepherd's Bush, W., have ordered three Bennis-Miller-Bennett improved patent smokeless chain grate stokers for a Babcock & Wilcox water-tube boiler from Ed. Bennis & Co., Ltd., Little Hulton, Bolton.

Lambeth.—The Borough Council has placed an order with Messrs. Strode and Co., Ltd., to wire and fix the electric light fittings in the Council Chamber and the Council Chamber anteroom at £18. The same firm is to supply wood fixing blocks and screws for certain of the ornamental electric light fittings throughout the building at £3 15s.

St. Pancras.—The Board of Guardians has received the following tenders for the supply of electric lamps to the South Infirmary:—J. C. Christie (accepted), 8s. 6d. per doz.; Charles Harrison, 9s. 8d. per doz.; Thomas Sampson, 10s. per doz.

Stepney.—The Borough Council has received the following tenders for columns and brackets in connection with the lighting of Broad Street, Horseferry Branch Road, Medland Street, and Wapping High Street, by arc lamps, and for the provision of columns or brackets for arc lighting extensions up to December 31st, 1908:—R. A. Bradshaw & Son, Retford (provisionally accepted), £361 10s.; W. Lucy & Co., Oxford, £392 5s.; W. Macfarlane & Co., Glasgow, £533 10s. 6d.

MANCHESTER.—Messrs. Bruce Peebles & Co., Ltd., have received the Manchester Corporation's order for eight Peebles La Cour motor converters in sizes ranging from 250 to 600 kw., each machine receiving 6,600 volts, and converting to either 415/425 for lighting, or 500/550 for traction.

ROME.—An order for 12 Woodeson patent water-tube boilers for the generating station at Rome has been secured by Messrs. Clarke, Chapman & Co.

SOUTHAMPTON.—The Town Council have accepted the tender of Messrs. Willans & Robinson, Ltd., for the supply and erection of the steam generator, and the tender of Messrs. Babcock & Wilcox, Ltd., for the supply of the boilers required at the electricity supply station.

WAR OFFICE.—Messrs. J. B. Saunders & Co. have been given a second contract for electric lighting in connection with the War Office buildings.

WOLFRAM (TUNGSTEN) METAL FILAMENT LAMPS, LTD.—The tender for the erection of this company's new works at Hammersmith has been let to Mr. J. McManus, at £34,[illegible]. There were thirteen tenderers, and the quotations ranged from the price of the accepted tender to £41,588.

COMPANIES' MEETINGS AND REPORTS

BRITISH WESTINGHOUSE CO.—In a circular issued to the shareholders dealing with the financial position of the company, the directors state that the reason for the necessity to issue the £300,000 prior lien debentures was brought about by the conditions of the money market in America, which precluded the American company, as had been its custom hitherto, from either furnishing financial assistance itself or acting as guarantor. In order that the whole amount of the new debentures which have been sanctioned by the shareholders shall be available for present and future needs, the American Company had agreed to accept in liquidation of the £186,374 owing to them, shares in the Traction & Power Securities Company at par. The £300,000 prior lien debentures is required to repay advances from the bankers expected to be reduced by February and March to £100,000; to meet accounts payable now due to the extent of £110,000, and to meet additional requirements on account of expansion of business, £90,000. Incidentally the directors point out that it has been decided to change the date for the termination of the financial year from July 31st to December 31st. Thus the next accounts to be presented to the shareholders will cover two periods, one of five months from August 1st, 1906, to December 31st, 1906, and the other from January 1st, 1907, to December 31st, 1907. The circular goes on to point out that the eleven months of 1907 to November shows a trading profit of £76,000, and after providing for interest on loans and debenture interest, there is a net profit of £17,780. The accounts and business of the company is to be dealt with in detail at the annual meeting, but the directors believe that if there be no unfavourable developments in industrial conditions, the position of the company will continue to improve.

According to a Reuter telegram from Pittsburg, the United States Judge has issued an order permitting the receivers of the Westinghouse Electric & Manufacturing Co. to exchange a claim of $874,882 against the British Westinghouse Electric & Manufacturing Co., Ltd., for shares in the Traction & Power Securities Co., Ltd., of Great Britain, equal at par to the same amount and interest, provided that the British Westinghouse Electric & Manufacturing Co., Ltd., secures bona-fide subscriptions for a bond issue of £250,000.

GENEVA TRAMWAYS.—The report for the period from December 17, 1906, to September 30, 1907, states that it having been found impossible for the original Geneva Tramways Company, Limited, to meet the full 4½ per cent. interest on the [illegible],000 debentures, the company went into voluntary liquidation on October 4, 1906, and the present company was registered under a scheme of arrangement sanctioned by the court on November 10, 1906. The scheme provided for the sale of the old company's assets to this company. The four-and-a-half per cent. debenture-holders of the old company are entitled under the scheme to 510,000 shares of £1 each (fully paid) and £255,000 four per cent. debentures of this company, to be distributed amongst them *pro rata* in lieu of their holding in the old company. The third (five per cent.) debenture-holders of the old company received under the scheme, in lieu of their holding and all accrued interest thereon, a *pro rata* distribution of [illegible],000 £1 shares fully paid in the capital of this company. The rights of the shareholders and income-certificate holders in the old company were, under the scheme, extinguished.

Digitized by Google

Applications for four per cent. debentures and shares in the company had been received to the date of closing the accounts in respect of £811,200 four-and-a-half per cent. debentures of the old company, and the equivalent four per cent. debentures and shares in this company have been allotted in exchange. Since the closing of the accounts further four-and-a-half per cent. debentures of the old company have been surrendered, the total to date being £843,700, in exchange for which £255,000 four per cent. debentures and 500,200 shares of this company have been allotted. The profit and loss account of the company for the period above referred to shows a gross profit on working of 502,148f., and, including the credit balance of 227,652f. brought forward from the previous period, makes a total of 789,800f. After making provision for the necessary contributions to amortisation, renewal, and reserve funds, amounting together to 179,332f., there remains a balance of 610,467f., out of which a dividend of 1½ per cent. has since been paid, leaving a balance of 310,467f. to be carried forward. New rolling stock is to be purchased to deal with the increasing traffic.

At the meeting on Monday, the report and accounts were adopted.

LOCH LEVEN ELECTRIC POWER.—At a meeting last week, the promotion of a Scotch provisional order, seeking an extension of the time limited by the Loch Leven Water Power (Amendment) Act, 1904, was unanimously agreed to.

NEW AFRICAN.—At the ordinary general meeting of this company on Friday, Sir Charles Euan-Smith, K.C.B., who presided, made some reference to the work of the Marconi Company, in which undertaking the New African Company has an investment of several thousand pounds. The chairman stated that after seven years of incessant work, the Atlantic had been successfully bridged by wireless telegraphy by Mr. Marconi, and the very difficulty of the task secured, in a sense, the Marconi Company from the possibility of competition. He expected on Saturday (January 11th), that the Marconi Company would establish a full service for the transmission of ordinary private messages. One of the main reasons for this not having been done before was that the Marconi Co. had been depending on single units of plant at their stations, and it had been considered advisable to duplicate parts of the running machinery in order to present risks of breakdown. Another reason for delay in throwing the service open to the public was the imperfect land line connections. This however would not be done away with until the Marconi Company was granted similar land-line facilities to those possessed by the cable companies. When these matters were settled, he saw no reason why wireless telegraphy across the Atlantic should not attain to a speed and accuracy of transmission equal to the present cable service.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith and Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic wire bars net c.i.f. port of arrival quoted on Tuesday night, was £65 to £65 10s. per ton (last week £64 10s. to £65 10s.).

LIQUIDATIONS, BANKRUPTCIES, &c.—Creditors of the City of Wellington Electric Light and Power Co. are required to send in particulars of their claims by January 24th to the Liquidator, Mr. H. E. Salt, 251 Winchester House, Old Broad Street, London, E.C. This company has been acquired by the municipality.

The trustee in the bankruptcy of F. E. Williams, electrical engineer, 328 Coventry Road, Birmingham, has been released.

A receiving order has been made against George Kaye Spiney, electrical engineer, 34 Pinderfields Road, Wakefield, Yorks. The debtor started in business as an electrical engineer at Dewsbury in 1899. His capital consisted of about £25 in tools and cash. About six years ago he was in partnership with Harry Birch, and they traded under the style of Spiney & Co. for three years, and the debtor was then appointed as electrical engineer for work for the Yorkshire Woollen District Tramways. The partnership with Mr. Birch was dissolved, and shortly afterwards the debtor was joined by another partner, who introduced £1,000 into the business. The debtor's capital was then £500. In October, 1905, he was paid out of the business, receiving £150 as his share. His statement of affairs shows gross liabilities amounting to £116 8s. 1d., all of which are expected to rank. The assets consist of cash in hand amounting to £10.

THE WESTMINSTER ENGINEERING CO.—The Westminster Engineering Co. inform us that, in order to devote their attention particularly to the manufacture of dynamos, motors, switchboards, arc lamps, and other specialities, they have disposed of the wiring, fittings, and installation branch of their business carried on since 1890 and up to this date at 16 Davies Street, Berkeley Square, W. Mr. Walter Riggs, who managed the branch for seven years, retains his position with the new proprietors, who will continue the business under the name of Girdlestone & Co., but neither the Westminster Engineering Co. nor Mr. J. O. Girdlestone, the managing director of the company, will have any interest in, or be in any way connected with, the business. The offices and sales department will remain at Victoria Road, Willesden Junction, as before, but customers who find it more convenient may still deal with Messrs. Girdlestone & Co., who are agents for the sale of the company's manufactures.

MISCELLANEOUS CITY NOTES

DIRECT UNITED STATES CABLE CO.—An interim dividend of 4s. per share, free of income-tax, being at the rate of 4 per cent. per annum, for the quarter ended December 31st, has been declared; the sum of £5,000 has been allocated to the reserve fund account; and £6,396 carried forward.

DUBLIN UNITED TRAMWAYS CO.—Subject to final audit, a dividend at the rate of 6 per cent. per annum for the half-year ended December 31st, 1907, has been declared upon both the preference and ordinary shares, together with a bonus of 1s. per share upon the latter. The sum of £5,000 has been set aside to the reserve fund, £1,000 to accident insurance fund, £10,000 for reconstruction and renewals, and £2,000 further provision against Exhibition guarantee, and £8,740 11s. 6d. has been carried forward.

MEXICO TRAMWAYS CO.—A dividend at the rate of 4 per cent. per annum for the three months ended December 31st, 1907, has been declared.

RIO DE JANEIRO TRAMWAY, LIGHT AND POWER CO.—Owing to increasing business in Europe, this company has opened offices at 46 Threadneedle Street, E.C., to which the registers, &c., will be transferred February 14th. The company also announce that, owing to the pressure of other engagements, Mr. William Mackenzie, of Toronto, has resigned the presidency, but will remain chairman of the board. Dr. F. S. Pearson has been elected president, and Mr. R. M. Horne-Payne and Mr. E. R. Wood, additional vice-presidents. Mr. George Flett, managing director of Dick, Kerr & Co., Ltd., has also been elected an additional director.

SIMPLEX CONDUITS.—The usual 6 per cent. dividend on the preference shares has been paid for the half-year ending December 31st, 1907. Dividend warrants have already been posted.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—In a recent issue of the *Tribune* it was stated that the scheme for dealing with the profit-sharing notes of the Underground Electric Railways of London would, in all probability, be issued within the next few weeks.

APPOINTMENTS AND PERSONAL NOTES

At the meeting of the Manchester City Council on Wednesday last week the recommendations with regard to the appointment of Mr. S. L. Pearce, Chief Electrical Engineer (which we gave in our last issue), were agreed to.

Mr. O. F. Francis, Borough Electrical Engineer, Kirkcaldy, who, as we announced last week, was appointed to a similar position at Carlisle, has decided to remain at Kirkcaldy. At the monthly meeting of the Carlisle Town Council on Tuesday, when the confirmation of Mr. Francis's appointment came up for consideration, Mr. Johnstone, chairman of the Electricity Committee, said Mr. Francis had acted honourably in the matter, an offer on the part of the Kirkcaldy Town Council having been spontaneous. The salary offered by Carlisle was £300 a year, with increments of £20 a year until it reached £400, but the Kirkcaldy Town Council had offered him £350 a year, with increments of £25 a year until the salary reached £400. The Electricity Committee has decided to offer the Carlisle appointment to Mr. Allen, chief assistant borough electrical engineer of Plymouth, who was second on the list of selected applicants.

Mr. W. S. Smart, of the northern branch of the Post Office engineering department, has been presented by his colleagues with a valuable petrolite lamp and case of pipes upon his retirement at the age of 60. Mr. Smart has served at Gloucester, Cardiff, and Hull, and was transferred to Darlington about three years ago.

NEW COMPANIES

A. B. CARTER & CO. (GERMANY).—This company was registered on January 9th, with a capital of £1,500 in £1 shares, to adopt an agreement with J. Wenk, of 107A Strand, W.C., and to carry on the business of electricians, mechanical engineers, suppliers of electricity, manufacturers of and dealers in electric, magnetic, galvanic, and other apparatus, builders, signmakers, printers, photographers, advertising agents, &c. The subscribers are:—T. H. Bower, J. Wenk, G. C. N. Perkis, G. R. Bell, T. Hulme, F. Partington, C. Ivory. No initial public issue. J. Wenk is the first manager and permanent director. Qualification, £150 shares or stock. Registered office: 107A Strand, W.C.

MERSEY MACHINERY CO.—This company was registered on January 9th, with a capital of £1,500 in £1 shares (500 10 per cent. cumulative preference), to act as selling agents for the Neville Machine & Tool Co., Ltd., in Southport, Ormskirk, Bootle, Widnes, Newton, Ince, Liverpool, St. Helens, Warrington, Wigan, Wirral, Northwich, Eddisbury, and Flintshire. The subscribers are:—J. U. Neville, engineer, T. J. Knowles, Mrs. M. A. Knowles, R. Hughes, A. E. Waterhouse, E. D. Symond, Mrs. M. E. Neville. No initial public issue. The number of directors is not to be less than two nor more than three; the first are J. U. Neville and T. J. Knowles. No remuneration. Registered office: 7 James Street, Liverpool.

SUMMARY

March 3rd has been fixed as the date for the inquiry into the proposed Home Office Regulations for factories in which electricity is employed. Mr. James Swinburne, F.R.S., is the Commissioner appointed to hold the inquiry. (Page 111.)

A report on a recent burn out on the District Railway has been issued by the Board of Trade. (Page 112.)

The Law and Parliamentary Committee of the Westminster City Council have presented a report on the electric supply Bills which will come before Parliament this session. The report is least unfavourable to the London and District Electricity Supply Bill, as it favours on general principles the advent of a new bulk supply company, whose operations would not affect the position of the Council with regard to the ultimate purchase of the existing companies supplying in Westminster. The Camberwell Borough Council have also considered the two Bills, and have decided to oppose both, in order to obtain amendments. (Page 112.)

Among the new metallic filament lamps which are already on the market in Germany, and will shortly be available in this country, are a 100-volt, 16-c.p. tantalum lamp, and 200-volt osram lamps of 40 50, and 100 c.p. It is claimed by the makers that the new osram lamps, both for 100 and 200 volts, will be suitable for use in any position. (Page 113.)

Prof. G. Kapp, in an afternoon lecture on the electrification of railways, delivered last Saturday at the Royal Institution, outlined the main features of the continuous-current single-phase and three-phase systems, and drew particular attention to the impending electrification on a large scale of the State railways of Italy and Sweden on the three-phase and single-phase systems respectively. (Page 113.)

In the discussion on Mr. G. W. Worrall's Paper on "Magnetic Oscillations in Alternators," read last week at the Manchester Local Section of the Institution of Electrical Engineers, several speakers referred to the application of the results to explain the phenomenon of humming in continuous-current machines. There was a disposition to question how far general deductions should be drawn from experimental results on a machine of special design, and some questions were asked regarding points still requiring elucidation. (Page 114.)

A Paper was read last Thursday by Mr. Horace Boot before the Society of Architects on the design of buildings for power-houses, in which the general requirements to which attention should be paid by architects when designing generating station buildings were dealt with. (Page 115.)

Digitized by Google

AN unusually large number of new students were elected at the last meeting of the Institution of Electrical Engineers. (Page 116.)

A PAPER was read by Mr. I. V. ROBINSON on Tuesday last before the Institution of Engineers and Shipbuilders in Scotland on the cost of power production, in which he compared the cost of power generated by water-power with that from stations driven by large gas-engines under the conditions of high load factor obtaining in electrochemical work on a large scale. (Page 117.)

THE Electrical Engineering Department of the Northampton Institute offers many facilities for young electrical engineering students, as well as for the more advanced. The course of instruction is spread over a period of four years for day students, and five years for evening students, and is divided into junior, intermediate, and senior classes. The more important features of the laboratories are described. (Page 119.)

IN this year's pantomime at Drury Lane a number of new electrical effects are introduced. (Page 120.)

THE Paper read by Mr. T. M. BARLOW before the Birmingham Local Section of the Institution of Electrical Engineers on January 15th contained the results of a series of experiments on the heat conductivity of assembled insulated iron stampings both in directions parallel and at right angles to their surface. The results emphasised the importance which should be given in dynamo design to the amount of edge surface of the stampings of a laminated iron core exposed to a cooling medium. The most efficient ratio of the linear dimensions of the edge side to the plate side of the core is given as 1 : 10, a much higher ratio than commonly in use. We are obliged to hold over our report of the discussion in which Dr. Sumpner, Prof. Kapp, Dr. D. K. Morris, and others took part, until our next issue. (Page 121.)

THE more recent additions to the generating plant at the Fulham Electricity Works include examples of high-speed reciprocating sets, and also a vertical shaft steam turbine, which form a remarkable contrast to the original slow-speed alternators. A new boiler-house has been erected recently, but a supply of steam is also obtained from the Horsfall destructor plant. This has now been altered so that no coal is ever burnt under the boilers, and the arrangement of the flues has been improved. (Page 125.)

AN automatic signalling system has been installed on a section of the Burton & Ashby Light Railway. (Page 128.)

IN an exhaustive report upon British trade with Canada, Mr. RICHARD GRIGG, a special Commissioner of the Advisory Committee to the Board of Trade, gives many reasons why British trade with the Dominion does not amount to a greater percentage of the whole than is now the case. He first admits that the geographical position of the United States is the all-important reason for the great disparity in the amount of trade done with Canada by that country and the United Kingdom, but he nevertheless believes that the British trader has himself to blame for the present position to a large exent. Little trouble, he says, has been taken to deal with the needs of the market. Goods are produced under British conditions and sent to Canada, where totally different conditions prevail. Direct communication between producer and buyer is recommended, and less reliance placed upon merchants and agents. The adoption of Canadian standards with regard to iron and steel, and the Canadian system of weights and measures is also necessary, whilst quotations should be in dollars and cents, and c.i.f. instead of f.o.b. (Page 132.)

THE discussion in London on Mr. J. F. C. SNELL'S Paper on "The Cost of Electrical Power for Industrial Purposes" was continued last Thursday. Mr. C. P. SPARKS and Mr. R. HAMMOND thought that his figures for the cost of electrical energy generated by independent plants was too low, while Col. CROMPTON supported them. Mr. G. W. PARTRIDGE thought he had over-estimated the diversity factor, and under-estimated the cost of laying mains in London. Messrs. E. W. COWAN, G. L. ADDENBROOKE, C. H. WORDINGHAM, W. H. BOOTH, G. H. CORRINGHAM, and A. M. TAYLOR also spoke. Several gentlemen desirous of taking part in the discussion were obliged to send their remarks in writing. These included Ald. Pearson, Messrs. W. C. P. Tapper, A. W. Heaviside, A. H. Shaw, G. H. Cottam, W. B. Woodhouse, and L. H. Hordern. A large proportion of the writers and speakers found fault with Mr. Snell's statement of the "correct" price that should be charged for power by existing undertakers, and the full discussion of the subject, together with the large number of numerical data given, was of considerable value. (Page 133.)

UNDER Electrical Science, in the British and American section, is a note on a null method of measuring ionisation. In the Papers abstracted in the Continental section, CATHIARD shows how to use a coal-gas flame as a rectifier. STARK draws some important conclusions from the Doppler effect in canal rays, and BORDAS describes the production of emeralds from sapphires by means of penetrating radium rays. (Page 138.)

LAST Friday evening Prof. T. E. THORPE gave a lecture at the Royal Institution upon "The Centenary of Davy's Discovery of the Metals of the Alkalis." A short review of the progress which has been made in the last few months in connection with electrolytic metallurgy shows that considerable work has been done in this direction, and points out directions in which future research would be of interest. A portion of the Notodden Atmospheric Nitrate Works was destroyed on January 7th by fire, when damage amounting to £8,500 was done. (Page 139.)

AMONG the specifications published by the Patent Office on Thursday last is one by the British Thomson-Houston Co. relating to the control of alternating current motors of the commutator type, and providing a means of braking for such type of motors. Another specification by the same firm relates to controlling devices which automatically open circuits in case of overload, and also prevent their being closed, while the overload continues. A specification by W. D. KILROY and EVERSHED & VIGNOLES covers an automatic electric starting switch. THE SUNDERLAND FORGE & ENGINEERING Co. and W. BLAIR have patented a device which relates to electric cranes and winches fitted with hand-operated or foot-power brakes, and provides a means for returning the starting-switch to its original position when the brake is applied. THE BRITISH THOMSON-HOUSTON Co. have also a patent automatic block signalling system for railways. A specification by G. MARCONI and the MARCONI WIRELESS TELEGRAPH Co. for a form of wireless telegraph transmitter which obviates the use of sparks or arcs in the oscillating circuit is also published. (Page 140.)

THE Southwick Electricity Works of the Brighton Corporation are in danger, owing to the weak state of the beach in front of them; an action for injunction against the Corporation is proceeding, as it is alleged that the old works and sub-station in North Road interfere with the service in a neighbouring church. The Clydebank Town Council are considering the transference of the Clyde Valley Electrical Power Co.'s order to the Stuthelyde Co. A breakdown of the electrical plant at Hull has had serious results, as three of the

Digitized by Google

largest sets are practically destroyed. The Corporation are ordering three new dynamos from the Lahmeyer Co. The Battersea Borough Council has agreed to the terms laid down by the L.C.C. with regard to the electrification of the tramways on Battersea Rise and St. John's Hill. The Southwark electricity undertaking shows a profit this year, for the first time; the council has refused the offer of a supply of electricity from the London Electric Supply Co. The Manchester Tramways Parcels Delivery continues to be successful. The Uxbridge and District Electric Supply Co., Ltd., are seeking to transfer a portion of their area of supply to the Metropolitan Electric Supply Co., Ltd. (Pages 116 and 141-142.)

TENDER forms, specifications, &c., in connection with the supply of 33 switchboards for private branch exchanges for common battery work required by the Australian Postmaster-General's department may be inspected at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, E.C. The Bristol Docks Committee invite tenders for cables and electric lighting installations at the Avonmouth Docks. Cable is also required by the Croydon and West Ham Corporations, and tenders for an extension to the switchboard at Edinburgh are invited. The Ilford Council are about to extend their generating station at a cost of £27,000. The Lowestoft Corporation has accepted a tender of Messrs. Siemens Bros. & Co. for an electric locomotive for use on their coal siding. A meeting has been held by the Dutch holders of profit-sharing notes of the Underground Electric Railways Co. of London, when a committee was appointed to examine any proposals for reorganisation. (Pages 144-146.)

THE Union Electric Co. on Thursday last held a reception at their works in Park Street, Southwark, and in the evening gave a dinner to their provincial representatives, staff, and friends at the Café Royal, Regent Street, W. (Page 145.)

As will be seen by a notice appearing in our advertisement columns, a date has been fixed for the inquiry to be held with regard to the proposed Home Office Regulations relating to the use of electricity in factories and workshops. As these regulations, if adopted, will apply on the one hand to electrical generating stations and sub-stations, and on the other hand to all places that are a factory within the meaning of the Factory and Workshops Act, it will be seen that their effect will be far-reaching. The owners of many electricity works may be put to large expense in reconstructing their switchboards and sub-stations if the regulations are passed in their present form and are made retrospective, although these places are not accessible to any but the engineers and skilled workmen who have a full knowledge of as to what are the dangers to be avoided. At the other end of the scale, even the small dressmaker who uses a ¼-h.p. motor for running her sewing-machine would be subject to further regulations than at present, and would probably be badgered by a second inspector, in addition to the one who makes calls to see that she conforms with the rules as to the overtime and meal-times of her assistants. As we have already emphasised in these columns, the very fact of the issue of a new set of regulations controlling the use of motors is to be objected to far more than any details in the draft regulations themselves. The latter can easily be modified, and doubtless Mr. G. S. RAM, the electrical adviser to the Home Office, has already made alterations to meet many of the specific objections that have been raised. In selecting Mr. James Swinburne as "Commissioner" to hold the inquiry, no better choice could have been made, for he is one of the few leading men concerned with the heavier branches of electrical engineering who has an interest neither in electricity supply or power companies, or in manufacturing companies. From the reference to him, moreover, it would appear that it would be quite competent for him to advise in his report that no further regulations were necessary, should he be satisfied on the evidence that electric driving is no more dangerous than other methods of driving subject to no such restriction. The date of the inquiry is March 3rd, and "objectors" should carefully peruse the notice advertising it on p. vii of our present issue, in order to see in what way they can avail themselves to the utmost of the privilege of appearing either in person or by counsel.

IN another column will be found a report by Major PRINGLE and Mr. A. P. TROTTER, of the Board of Trade, referring to an occurrence which has been described as an explosion a week or two ago at Sloane Square Station. A good deal of unnecessary alarmist writing has been allowed to appear in the general Press, and we are pleased to see that this report has been widely circulated, for it clearly shows, by describing the details of an actual case, how small is the danger from fire in properly constructed electric railways. The authoritative voice of the experts of the Board of Trade is of the greatest use in helping to remove the real source of danger which, in such circumstances, is not fire, but panic.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 23RD.

Institution of Electrical Engineers: Leeds Local Section.

7.15 p.m. Meeting at the University, Leeds. Paper to be read:—"Notes on the Development of Turbo-Alternators," by Dr. Pohl.

Institution of Electrical Engineers.

8 p.m. Meeting at the Institution of Civil Engineers, 25 Great George Street, London, S.W. Paper to be read:—"Standard Performances of Electrical Machinery," by Rudolph Goldschmidt.

FRIDAY, JANUARY 24TH.

Physical Society.

5 p.m. Ordinary meeting at the Royal College of Science.

SATURDAY, JANUARY 25TH.

Royal Institution.

3 p.m. Afternoon Lecture II., on "The Electrification of Railways," by Prof. Gisbert Kapp.

North-East Coast Institution of Engineers and Shipbuilders.

7 p.m. General Meeting at 4 St. Nicholas Buildings West, Newcastle-on-Tyne. Among the subjects down for discussion is "Electricity Compared with Gas for both Lighting and Power."

TUESDAY, JANUARY 28TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology, Whitworth Street, Manchester. Paper to be read:—"The Design of Polyphase Induction Motors," by W. D. Redfern.

WEDNESDAY, JANUARY 29TH.

Society of Arts.

8 p.m. Ordinary Meeting, at John Street, Adelphi. Paper to be read:—"The New Patent Act," by J. W. Gordon.

FRIDAY, JANUARY 31ST.

Royal Institution.

9 p.m. Evening Discourse by Prof. Ernest Rutherford, F.R.S., on "Recent Researches on Radio-activity."

FIRES ON UNDERGROUND ELECTRIC RAILWAYS

THE following report, by Major Pringle and Mr. A. P. Trotter, addressed to the President of the Board of Trade, referring to an occurrence at Sloane Square Station on January 8th, has been sent us by the Board:

SIR,—We have, in the usual course of our duty, inquired into the circumstances under which an explosion and electric flashing took place in a car, on the evening of January 8th, at Sloane Square Station on the Metropolitan District Railway. We made a very careful examination of motor-car No. 34, which alone was concerned in this case, before any repair work had been carried out, or any of the effects of the explosion and flashing had been removed.

Above floor level there was some blistering of the varnish on the woodwork surrounding the end left-hand window and doorway, and two panes of glass were blackened with smoke and fumes. No glass was broken, and it was possible by rubbing off the blistering on the wood to see that the red paintwork underneath was undamaged. Below floor level the metal pipe carrying the electric lighting wires and a metal junction box were fused. The underside of the timber flooring immediately above this pipe and junction box was charred in places. The charring nowhere exceeded a quarter of an inch in depth. No mark of fire could be found inside the car on the flooring, seats, or sides.

We may here remark that all the woodwork on the company's cars in proximity to electric conductors has been rendered non-inflammable. This and other occurrences of a similar kind have proved that the wood will char under the effect of intense heat from electric flashing, but will not catch fire. The real combustibles in this fire, if we use the word, were copper, iron, and brass. Such electric arcs continue until they exhaust or burn themselves out, or until the current is cut off, as was done at Sloane Square. The ordinary method of extinguishing a fire is useless for electric arcs.

This particular case was caused in all probability by failure of the insulation of the electric lighting wires owing to damp. The heating of the wires resulted in the liquefaction of a small plug of bitumen. An explosion of bitumen vapour followed, causing smoke and fumes. Subsequently, electric flashing took place along the pipe and at the junction box under the car. The conductor in charge of the car states that he immediately entered the door at the corner where the explosion had taken place, and worked the air valve which actuates the double doors in the centre of the car. The doors opened in the usual way; they had not to be forced or held apart. The passengers, eight in number, stepped out on to the platform through the open doorway without any apparent panic or alarm. No complaint of injury or danger was made to either the station inspector or any of the company's officials. Arrangements also exist, on underground as well as on tube railways, to allow passengers in case of need to descend from a train at either end.

In our opinion the apprehensions of danger which have been expressed by writers to the newspapers are not justified by the facts. The main danger in any such cases of fire will be from panic. For this reason we deprecate the writing for publication of alarmist letters.

We are, Sir, your obedient servants,

(Signed) J. W. PRINGLE (MAJOR),
Inspecting Officer of Railways.
(Signed) A. P. TROTTER,
The Electrical Adviser to the Board of Trade.

TO THE PRESIDENT OF THE BOARD OF TRADE.

Wireless Telegraphy.—The North of England Steamship Owners' Association has decided to continue urging upon the Board of Trade the advisability of establishing communication between the Newarfs and Cockle Lightships, and the shore, as a medium whereby ships' orders might be readily transmitted. The Margate Corporation have forwarded a resolution to the Board of Trade urging the desirability of installing a system of wireless telegraphy between the Long Sand lightships and the shore.

Audit of Electric Lighting Companies' Accounts.—Several of the London borough councils are protesting against the proposal of the Board of Trade to dispense with the services of an official and separate auditor in connection with the annual audit of the accounts of electric supply companies. Camberwell, Battersea, Paddington, Lambeth and Bermondsey have taken the matter up, and an appeal will be made to the Board of Trade. We gave the letter of the Board of Trade in reference to the proposal in question in our issue for December 12th, page 944.

THE LONDON POWER BILLS

THE Law and Parliamentary Committee of the Westminster City Council has drawn up a long report with regard to the electric supply Bills to be presented during the coming Session. The committee state that it seems probable that Parliament will be compelled to sanction some scheme for cheapening bulk supply, and in the absence this year of a municipal scheme the contest lies between the creation of a new bulk supply company, and the practical amalgamation of the existing companies. The latter scheme would involve an entire change in the character of many of the existing undertakings, by gratting on to them what would be practically a separate existing undertaking; and it would inevitably lead to such an intermingling of assets and interests, and to such an overlapping of areas, as would render insuperable the difficulties of ultimate purchase on anything resembling the original lines. The establishment of a new and distinct bulk supply undertaking, the report continues, need not have these effects, and might be an advantage to the present undertakers, whether companies or local authorities, as it would furnish them with a cheap bulk supply supplementary to the supply of those who possessed generating stations, whilst saving the expense of the erection of new generating plant in the numerous cases where the powers of purchase will extend merely to distributing plant. It would seem, therefore, that, from the point of view of the local authorities, as prospective purchasing authorities, the better course would be to seek to restrict the existing companies to their present functions and areas, and to keep intact the powers of purchase under the Electric Lighting Acts, whilst entrusting a separate undertaking with bulk and power supply. In one way the position of Westminster is at present exceptionally favourable, inasmuch as the City Council is in the position that if in 1931 they exercise their powers of purchase of the undertakings of the St. James and Pall Mall and Westminster companies, they will at the same time acquire on very favourable terms the generating station in Marylebone, and will thus have a source of supply which, independently of any other generating station, would go a long way to meet the needs of the whole of Westminster, as far as regards electric lighting. The committee recommend, therefore, that the most favourable course for Westminster would be the maintenance of the present position, with the addition of a bulk supply undertaking, which could be optionally resorted to should the Marylebone generating station prove insufficient. The report points out, however, that the London and District Electricity Supply Bill would give its promoters the power of direct supply to the consumer, practically in competition with the authorised distributor, and would also give them large powers of street breaking. Referring to the London Electric Supply Bill, promoted by the companies jointly, the committee states that the measure threatens to destroy the power of Westminster to purchase the Central Company's generating stations, and thus to deprive the City of a valuable asset expressly conferred by Parliament only three ago. In regard to the London (Westminster and Kensington) Electric Supply Company's Bill, the committee express the opinion that the effect of the measure, if passed, would be to render more difficult the question of purchase by local authorities. Petitions are to be presented against each of the three Bills.

The Camberwell Borough Council have also considered the London Electric Supply (Joint Committee) Bill and the London and District Electric Supply Bill. Reporting on these Bills, the Town Clerk and Borough Engineer, having pointed out at the outset that the former Bill is promoted by the fourteen electric lighting companies having powers for the supply of electrical energy within the administrative County of London and adjoining districts, expressed the fear that if the combination and amalgamation of the electricity companies concerned is permitted it will further complicate the difficult problem of electric lighting in London, and that it would be far better for the existing system to remain than for a huge new vested interest to be created. If the Bill proceeded, it was suggested that several amendments are required, one of which should be for the maximum charges to extend to light as well as power, and further that all capital raised by the company should be devoted only to the construction of works required for carrying on the business. It was thought by the Town Clerk and Engineer to be also necessary for the purchase clause mentioned in the Act of 1888 to be reinstated in place of the purchase clause in the Bill, and it was further urged that the authority for ultimate purchase should be the London County Council, or otherwise the whole question would again have to be fought out in Parliament. It was thought that the clause providing for the appointment of an auditor by the Board of Trade should be amended so as to provide for power to the local authority to send representatives to the auditor with the right to appeal to the Board upon any point which may arise pertinent thereto. The recent value placed upon electricity undertakings under arbitration was shown in the case of Marylebone, and what the goodwill of a monopoly was worth was shown by the fact that the goodwill realised practically twice the amount of the whole capital expenditure upon the works by the various water companies when acquired by the Metropolitan Water Board. The Council was recommended to petition against the Bill on the preamble, in order to obtain amendments and also clauses for the due protec-

Digitized by Google

tion of the exclusive right which the Borough now enjoys with regard to the special purchase clauses on undertakings as applied to Camberwell, which, if the Bill be passed in the present form, would, it was said, disappear without compensation, and the goodwill value of which is now worth many thousands of pounds. The Council adopted this recommendation, as also a proposal to petition against the London and District Electric Supply Bill.

NEW TANTALUM AND OSRAM LAMPS

THE principal disadvantages in connection with the metallic filament lamps at present on the market in this country which have prevented their more universal adoption, especially for private lighting, have been the fact that two lamps in series are required for 200-volt circuits, and the inconveniently large units of light which have to be adopted. The announcements, therefore, that in the case of the tantalum lamp a 16-c.p. lamp has been produced, and in the case of the osram lamp single lamps for 200-volt circuits have already been made, are of the greatest interest.

The new small tantalum lamp is already being advertised by Messrs. Siemens & Halske in Berlin, although we understand from Messrs. Siemens Brothers' Dynamo Works, Ltd., that deliveries will not be commenced in this country for a month or two. It is of 16 (Hefner) c.p. for 100 to 120 volts, and takes a current of 0·22 to 0·25 amperes, or 1·5 to 1·7 watts per Hefner c.p., and in general appearance is similar to the more familiar 25-c.p. lamp. The average life is stated to be 800 to 1,000 hours. The addition of this lamp to the series gives four sizes of 16, 25, 32, and 50 c.p. respectively for circuits in the neighbourhood of 100 volts.

We have already referred to the 200-volt osram lamp for 100 c.p., which will be obtainable in this country in a few weeks' time, and it is interesting to know that 40 and 50 c.p. osram lamps for 200 to 250 volts have also been made. We understand that it will be some considerable time before they will be obtainable in this country in any quantity, although they are already advertised for sale in Germany. Another improvement which is to be applied to the new osram lamps both for 100 and 200 volts is a new form of flexible support to the filament which will permit of their being used in other than the vertical position.

The Poplar Boiler Explosion.—A Board of Trade report by Messrs. A. A. Hudson and J. H. Hallett has been issued on the boiler explosion which occurred on August 16th last at the Poplar Electricity Works, when two stokers were killed. The boiler in question was of the Stirling type, with three main steam drums, a mud drum, and 630 tubes. A superheater was also fitted. By the explosion one of the tubes in the front bank of tubes was split and bent, and the tube drawn out of the front upper drum of the boiler, and vapour and ashes were blown out through the cleaning doors of the combustion chamber. The cause of the explosion was overheating of one of the tubes in the front bank of tubes, owing to its being blocked with scale; the tube in consequence split and bent, and withdrew from the front upper drum. The Commissioners consider that the staff employed to look after the works were highly efficient. Upon an examination of the boiler after the explosion, it appeared that a tube in the fourth row of the front rank had bulged and split, and had also become bent, so that it had drawn itself out from the upper drum, leaving an aperture the size of the tube in the upper drum. It was also found that the tube which had split was completely blocked with deposit at the bend at the lower end of it, while seven other tubes just round the burst tube were considerably choked with deposit in a similar position, not absolutely choked, but choked so much that Mr. Clark, the inspector from the Stirling Boiler Co., stated that he was only just able to force up them a ⅜ in rod. In dealing with the possible causes of the accumulation of excessive deposit in the burst tube, the opinion is expressed that during the last examinaton the particular tube must have been missed by an oversight, and attention is called to the exceptional care in cleaning which is required with bent tubes of the description used. The report continues:—"With regard to the supply of water, there is no doubt in our minds that the failure of the softener to perform its work did accelerate the deposit in this boiler." The defective action of the softener was not discovered till after the explosion.

RAILWAY ELECTRIFICATION

AT the Royal Institution on Saturday last Prof. Gisbert Kapp, of the University of Birmingham, delivered the first of a course of two lectures on the electrification of railways. The lecturer dealt briefly with the history of electric traction, and then passed on to consider the advantages to be gained by the electrification of existing railways. There is no doubt that a more frequent, quicker, and more comfortable service is obtained with electric traction, but it has yet to be shown that electric traction is more economical than steam traction; indeed, we cannot expect the short lengths of line already electrified to show much economy, but when the extensive electrifications now being carried out in Sweden and Italy are completed a great saving, as compared with steam traction, may be expected. The economy will, of course, be greatest in such countries where coal is dear.

The high acceleration due to the large starting torque obtainable with the electric motor, to the high value of the adhesion weight in the case of motor-cars, and to the capacity of an electrical equipment for developing an amount of power far in excess of its rated output for a short time, has increased the frequency of the service, while the steam locomotive is limited in these respects by the size of its boiler. The maximum safe speed round curves is also higher for an electric locomotive than for a steam locomotive, as the centre of gravity is much lower in the former case. The greatest difficulty to be encountered in any electrification is the arrangement of the contact rail or wire. The third rail is dangerous and creates even greater difficulties at points and crossings than the overhead wire, which latter, however, may in some cases interfere with the driver's view of the signals.

The lecturer described the Wilgus-Sprague protected under-running third rail as used on the New York Central and other American railways (see ELECTRICAL ENGINEERING, January 9th, p. 38), and various typical forms of catenary suspension. The different systems were classified with regard to the motors used., *i.e.*, whether continuous-current, three-phase, or single-phase. The single-phase motor must be heavier for a given torque than the continuous-current motor, as the effective torque is only about 70 per cent. of the maximum. The three-phase motor is lighter than either the single-phase or the continuous-current motor for a given output, as the only limit to the armature strength is the heating, whereas the field distortion with the resultant commutation troubles is the principal limiting factor in the other two types.

Prof. Kapp then passed on to the two different methods of obtaining variable speed with three-phase motors. First, the stator winding may be arranged so that two different numbers of effective poles can be produced. In such a motor, however, the rotor must be provided with two independent windings and two groups of slip-rings. Secondly, cascade working may be employed, in which the stator of the second motor is supplied with current from the rotor of the first motor. If the two motors have different numbers of poles, three running speeds can be obtained. The stator of the first motor in the cascade arrangement is wound for the line pressure, say, 3,000 volts; the rotor pressure is, however, necessarily much lower, and the stator of the second motor must be wound for this low pressure. Consequently, if the second motor is to be used by itself for a third running speed, a transformer must be included in the equipment. A recent improvement, introduced by C. de Kandó, however, renders the use of a transformer unnecessary: the stator of the second cascade motor has three winding groups per phase, which are arranged in series with star connection for working direct at the line voltage, and in parallel with delta connection for working in cascade from the rotor of the first motor, the pressure in the latter case being rather less than one-fifth the pressure in the former case. (A full description of this system was given in ELECTRICAL ENGINEERING, Vol. I., p. 988, in connection with the new locomotives in use on the Vallellina Railway.)

The Italian Government is electrifying some 340 miles of track of the State railways on the three-phase system, the estimated cost of which will be £3,000,000. The chief engineer for the Swedish Government, Mr. R. Dahlander, has decided to adopt the single-phase system. Five large hydroelectric power stations will supply current at 50,000 volts to thirty-seven substations, which will transform down to the trolley-wire pressure of 15,000 volts. The first report of the Special Commission appointed by the Swiss Government has been published, but this deals only with the probable amount of power necessary, which is estimated to be some 100,000 h.p. on the average; the maximum load may be from twice to five times this amount.

The second lecture will be delivered on Saturday next, and will include descriptions of recently electrified lines

MAGNETIC OSCILLATIONS IN ALTERNATORS

Manchester Discussion

A DISCUSSION of some length followed the reading of Mr. G. W. Worrall's Paper on "Magnetic Oscillations in Alternators" on Tuesday, January 14th, before the Manchester Local Section of the Institution of Electrical Engineers. The Paper itself, in which Mr. Worrall gave an account of the continuation of a series of experiments described in a former Paper making a distinction between "pulsations" and "to and fro" movement of the flux, and investigating the conditions under which each is a maximum, was given in our last issue on p. 95.

Mr. S. L. PEARCE (Chief Electrical Engineer, Manchester Corporation), who was in the chair, made a few remarks before calling on other speakers, in which he emphasised the importance of Mr. Worrall's results to dynamo designers.

Dr. E. W. MARCHANT (Liverpool University) thought that the author's observation of the effect of the pole width on the ripples in the E.M.F. wave produced by an alternator was a very interesting one. The method of getting rid of ripple by altering the size of the air gap at the edges of the pole shoe was, of course, very well known; but the fact that shaving off the edges of the pole affects these ripples so much had not, he thought, been hitherto noticed. Mr. Worrall had said that the experiments of Fischer-Hinnen showed that the noise produced by a dynamo was greatest when the pulsation in the magnetic flux was a maximum. In Fig. 2 there was a maximum for this pulsation when the ratio between the polar arc and the tooth pitch is 6, a whole number. In Fig. 3 it is seen that the best wave is obtained when the ratio of polar arc to tooth pitch is 5·5, so that when there is a maximum magnetic pulsation there is a minimum magnetic swing, and *vice versa*, so that it would appear that a machine that is not noisy must have a bad wave, and, on the other hand, if the machine has a good wave, it is bound to be noisy.

Mr. W. CRAMP suggested that there were three types of machines concerned with this question of magnetic oscillation. First, there is no doubt that a great many D.C. machines have given trouble on account of the noise due to the flux changes. In any case, there is a vibration set up by the armature teeth which seems at some particular speed to correspond with the natural period of vibration of some part of the machine, such as the pole tip. But he had come across a case in which the noise was very loud at a particular speed, although the machine had a cast steel pole and no pole tips. The question arose whether such noise was due to the "swing" or the "pulsation." If the latter, one must conclude from the Paper that a ratio of polar arc to toothpitch at 5·5 must be used; but if it is due to the "swing," a ratio equal to a whole number would be required. Next, there was the case of the alternating current motor. Everyone who had dealt with alternating current motors knew that there was a good deal of difficulty in avoiding what was known as "cogging," and that such cogging is due to variations of reluctance in the magnetic circuit due to the effect of the teeth passing the slots. To get rid of "cogging," it was usual to choose a prime number of slots for the rotor. If this cannot be done, then, according to this Paper, a number of slots must be chosen, so as to get the minimum main magnetic change, *i.e.*, corresponding to that which Mr. Worrall gives as 5·5. Lastly, there was the case of the alternating current generator, in which there was with one ratio a big change of flux, and with the other the ripples, both of which should be avoided. Mr. Worrall said that in order to obtain the minimum change of flux a ratio 4 polar arc to tooth pitch $5\frac{1}{2}$ should be used, and in order to get rid of the swing a whole number should be used for the ratio. Now, it seemed to follow from Fig. 4 that the swing entailed a complete movement of flux right over the pole face. For the production of the ripples on the top of the no-load E.M.F. wave probably means that the whole flux moves across the pole face, which would not have been expected. If the whole flux does move across the pole face, it was evidently possible to get rid of the ripples on the top of the wave by putting slots in the pole piece itself, so that the reluctance of the part under the pole should change in the opposite direction to that in which it changed when the slots and teeth left the pole. Thus it ought to be possible to design an alternator with practically no magnetic oscillations. There were one or two further questions which he would like to ask Mr. Worrall. In Fig. 2 the change in the flux seemed very abnormal, and one wondered whether there was anything curious in the construction of the machine. The air gap seemed small for the size of machine, so that he questioned whether the conditions were quite those met with in ordinary practice. The width of the slot and the ratio of the air gap to slot were not very extraordinary, but the ratio of the air gap to slot depth was rather less than one would meet with in ordinary practice. In some of the figures ripples were only apparent in the tops of the waves, but he did not know why they did not also appear down the side. Lastly, he asked Mr. Worrall whether he had anything to offer us in the way of conclusions as to the effect on this particular alternator of using closed slots.

Mr. J. S. PECK (British Westinghouse Co.) agreed as to the importance of eliminating the ripples from the E.M.F. wave. The semi-closed slot would help matters very much, as would also increasing the number of slots. He was rather surprised at the statement:—"As successive slots pass a given point in the pole-face the armature current opposite that point would not be quite constant, but the flux displacement was not found to vary within the possibilities of measurement." He would have thought that even with a three-phase alternator there would be sufficient difference between the currents in the slots at different times to make quite a decided difference in the measurements. Mr. Worrall stated that with a single-phase armature the effect would be marked, and he would like to ask whether he had ever made any tests on a single-phase alternator to find out what this flux displacement amounted to.

Dr. E. ROSENBERG (British Westinghouse Co.) said:—What we must always bear in mind is that these facts have been attained only on one particular machine, and that the results are valid only for this machine, and we must not generalise. For this particular machine, with this particular air-gap, and particular size and number of slots, the magnetic pulsations are the smallest for a pole-face equal to $5\frac{1}{2}$ slots, and the biggest for a pole-face equal to six slots. If we alter the air-gap, and alter the number of slots per pole, the results may be different. It is interesting that the author has come to the same conclusion as Fischer Hinnen in his researches on humming, but I may also say that the results obtained by Prof. Hinnen are not applicable to all kinds of machines, and there are many motors which could not be made noiseless by applying Fischer-Hinnen's rule. Figs. 5 and 6 apparently give a theoretical explanation for the results obtained. Mr. Worrall took exactly a fringe of 45 degrees, but, of course, the fringe has no definite limits. We know that it gradually decreases, and if we choose any other angle for the fringe the result is quite different. The ripples on the E.M.F. wave have a specially marked result if a dynamo works in parallel with another dynamo, or is driving a synchronous motor with another wave shape. Then the higher harmonics produce a current in a circuit that contains nothing but the self-induction of the two machines, and this current may be higher than the main current. I once published a no-load current curve of a synchronous motor with harmonics of the 5th 6th, 7th, and 11th order, that were nearly three times as big as the value of the fundamental current. The fundamental curve shows 2·6 amps., and the current measured was 7·2 amps. In another case the ratio was 5·5 and 15. I should like to ask Mr. Worrall in what manner he succeeded in getting exact resonance in his Fig. 7.

Dr. C. C. GARRARD (Messrs. Ferranti, Ltd.) made some remarks upon the higher harmonics in the E.M.F. waves of star-connected machines and the effects produced when the neutrals were earthed.

Mr. J. FRITH referred to similar experience with regard to the humming of machines to that of Mr. Cramp. He believed it was entirely a mechanical effect on the pole tip due to the intermittent magnetic pull of the teeth. He had noticed it quite as much with machines with laminated pole shoes, and it would nearly always be cured by using the same average width of pole, but staggering it across the slots. With regard to the tooth ripples being very much more marked on the top of the curve, he suggested that this was partly due to the fact that they did not show so much when they were on the sloping sides of the curve.

Mr. G. W. WORRALL, in reply, said:—In this Paper I have referred to only one machine, but I have attempted to generalise the results as far as possible, and although I must admit that any other machine will have results either similar or perhaps somewhat different to the results I have given, I have endeavoured to lay down the laws governing these results, so that if we understand the machine we are dealing with, we shall be able to understand the cause of the phenomena which we may have observed. If we have a machine that will give a large fringing, then we must know that there is some effect on the oscillations, although it is remarkable that the Fischer-Hinnen results gave the same impressions that I have obtained. The P.D. waves that I gave in Fig. 8 rather point to a confirmation of my results. There we have machines radically different to those on which I conducted most of my experiments. Referring to the remarks of Professor Marchant as to the humming, according to my ear the pitch remained the same for all sizes of polar arc. Respecting the remark that if you want a good smooth wave we must have a loud noise, and if you want a silent machine we must have a bad wave, that is at all events true as regards my machine, for I noticed that the humming distinctly

Digitized by Google

diminished in intensity as I reduced the polar arc. Mr. Cramp made some remarks regarding the oscillations in the zero portion of the wave. One reason for their apparent absence has already been given in the discussion, and that is the wave is more or less steep at the side, and, therefore, the ripples would not appear to be so heavy; but I think there is another reason, which is probably due to the fact that any variation in the main flux is bound to be subjected to a damping effect of the iron. If we consider a magnetic circuit, then we have the flux threading through, and any variation of that main flux is subject to a certain damping action of the whole circuit. The actual percentage is not very large; the maximum in the pole shoe is only 0·2 per cent. The maximum under the limb is 0·0094. When we consider the main flux that is subject to a damping action, we must consider the movement of the flux in the air gap, that is subject to a very much greater damping action. Mr. Cramp made some suggestion regarding placing teeth in the pole face in order to get the backward movement of the flux. In order to discuss that point it would require some greater knowledge than I possess at present of the nature of this swing. One gentleman asked me if the swing took place over the whole pole face. I must admit I have not yet devised any method of observing that swing independent of the local oscillations. I think we must distinguish between the flux swing of the total flux and the local swing over a single tooth, and I cannot yet see how to actually carry out any oscillograph record of measuring this total swing, and distinguish it in that record from the main pulsation or from the local swing over the tooth, so that whether this main swing takes place over the whole pole face, as it certainly appears to do, or whether it takes place in any other way, I cannot say. With regard to the point *re* closed slots. In a previous Paper I just touched upon the subject of the main variation of the total flux. I showed there that the introduction of a bridge in magnetic contact over the slot made very little difference to the change in the whole flux as the teeth passed, *i.e.*, taking a smaller armature, one with closed slots and the other with open slots, the main pulsations appear to be the same. Now that is probably due to the fact that when you consider the reluctance of the whole circuit and the reluctance of the air gap, then any thin bridge over the slot will hardly have much influence on the main flux, but of course it has a very great influence on any local oscillation in the local flux, but not in the main flux. Mr. Peck drew attention to the effect on single-phase generators, and asked me if I had made any observations on single-phase generators of the effect of the varying position of the line of symmetry of the flux entering the teeth. I have not made any observations of this, so that I cannot say, experimentally, whether it takes place, but it appears to me reasonable that, at all events, there would be more for a single-phase than a three-phase generator.

DESIGN OF BUILDINGS FOR GENERATING STATIONS

MR. HORACE BOOT read a paper last Thursday before the Society of Architects on the "Planning and design of buildings for power works for the generation of electricity." In the introductory portion of the paper he summarised the conditions to which attention should be paid when choosing a site for a generating station, mentioning particularly the importance of facilities for fuel and water supply, and carriage of heavy material, the question of nuisance to adjoining property owners, and the nature of subsoil and foundations. Passing on to the buildings themselves, he classified the requirements briefly as follows:—

(1) The main engine room, where the engines and generators are fixed. (2) The boiler-house, where the boilers and automatic plant relating thereto are fixed. (3) The pump house and auxiliary plant, where feed pumps and small machinery in general is housed. (4) Coal and fuel storage. (5) Workshops for undertaking repairs. (6) Stores and storekeeper's office. (7) A battery room, if batteries are used. (8) The testing room. (9) Baths and wash-houses for the engineers' department, general offices, men in charge and engine drivers, also for the stokers and men whose calling makes them require separate lavatories. (10) Chimney shafts. (11) Foundations for engines, boilers, pumps, main flues, and general work of a builder's character.

For the above, the details and space required, height, and depth of foundations, &c., should be given to the architect by the consulting engineer employed to carry out the work, and he should also inform the architect about how much the undertaking can afford to spend upon the buildings, as distinct from the other portions of the works.

A table was then given showing the enormous variation in the cost of buildings of different stations. The two extremes quoted were £2·76 per kilowatt of plant capacity installed at Brighton, and £23·55 per kilowatt at the Neasden power-station of the Metropolitan Railway.

Whilst in no way sacrificing efficiency, the cost of the buildings should be kept low, because capital outlay plays a very important part in the cost of production of electricity, and very often in the case of small works in their early days, the capital outlay on buildings is likely to hinder the healthy and rapid development of the undertaking, owing to the necessity of charging a higher price per unit than would have been the case had the capital outlay been kept moderate, or rather in proportion to the business undertaken.

In alluding to refuse destructors, Mr. Boot said:—"It is the practice of several authorities, and I venture to think the practice will increase rather than diminish, to combine the destruction of refuse for the generation of steam, and where such is the case, the refuse destructor house should be so designed as to provide for an inclined roadway for the carts to deliver into the place from which the charging of the furnaces can be done direct. The destructor building is better apart from the engine-house, otherwise trouble will be experienced by hot bearings caused by the dust. The refuse house should be well ventilated, and arrangements made for disinfection and cleansing."

Plans of typical power-houses were shown, and the different requirements of a station with gas or oil-driven plant were pointed out. In the case of producer gas plant, for example, of course a boiler-house is not required, but in its place it is usual to erect open outdoor buildings, so that noxious fumes given off by the gas making cannot concentrate, but are at once carried away. With regard to the engine-house, it is designed on much the same lines as that required for steam, with the exception that much more perfect ventilation must be provided for—either natural or forced. In the case of oil engine plant, the buildings become much simpler, especially in the case of works employing engines of the "Diesel" type for prime movers. Here, practically only an engine house and offices are required; the oil storage can be kept on the roof or somewhere adjacent outside the buildings.

When dealing with steam as the prime mover, the space required may vary very much; for instance, in the early days it was customary to use slow speed rope-driven dynamos; these have been replaced with high speed engines, taking up much less space, and again—certainly in big power stations—the steam turbine is rapidly taking the place of the reciprocating engine. In the case of steam-driven sets, the boiler and engine houses are practically one building; but in the case of gas engines, the gas houses are separate from the main engine-house, the gas holders are placed outside, and all is arranged for thorough ventilation. The space required by turbines is very much less than for reciprocating engines, although that is not altogether the reason why turbines have been adopted.

Some examples were mentioned to show the gain in floor space by the adoption of turbines in place of reciprocating engines. At Shoreditch the engine-room contains two 800 kw. sets, and two 1,500 kw. steam turbines side by side. In a space of 28 ft. by 50 ft., 3,000 kw. of steam turbine plant is installed; whereas the 1,600 kw. of reciprocating engines occupy 48 ft. by 46 ft. At the Metropolitan Railway power-house, Neasden, the total space taken is 324 ft. 7 in. by 102 ft. 6 in. for the engine-room, with an addition of 114 ft. for the chimney and economisers.

Dealing with the general style of buildings required, it was pointed out that buildings must be fireproof. The materials used are best left to local conditions, and whether the building is a brick or steel one depends upon the amount available for such building. If the buildings are situated in a town, there should be plain ornamentations: if the walls are of brick, the use of white glazed bricks up to a height of 10 ft., finished off with chocolate glazed bricks with a cornice, forms a neat and ornamental finish inside. The walls, or rather pilasters, must be of sufficient strength to carry rails on either side for the crane, which crane should be designed to lift not less than 10 tons, and in the case of big power stations, 20 tons. The question of what forms the best flooring for an engine room has often been debated, and so far as appearance goes it is hard to beat tesselated paving; but in this case, it is necessary to section it up in squares, and the author has found that if this is done, and a gap, of say half-inch left, this space can be run in with a very hard setting compound, having sufficient give in it to prevent the pavement cracking. Another form used is tiles; but the trouble is, that when heavy tools are often dropped, a tile is often broken. Wood block flooring has been used, but with oil and grease about, it is very difficult and expensive to

Digitized by Google

keep clean. Where, however, appearance does not matter so much, he was in favour of using blue bricks placed sideways, which forms a most efficient flooring so far as wear goes, but it does not look so neat as a tessellated one.

It was mentioned that in America the boilers are often placed one above the other on different floors; but this practice has not been copied over here, except in one case, and there are undoubtedly objections to it. The height of roof varies according to the plant to be installed. Should it be decided to instal steam turbines, the height can be kept low; on the other hand, if reciprocating engines are installed, the height of the roof will be much more. Whatever form of plant is installed, a travelling crane is indispensable.

It is important in designing to take special care with regard to the levels, as where heavy machinery has to be managed the engine-room floor should undoubtedly be all on one level. Again, it is important where main flues have to be constructed, and economisers installed, to see that they are not constructed below the ground water level, as experience has proved it to be very difficult to keep the water out of the flues, although many schemes have been employed. With regard to drains, it has been found that large quantities of dirty oil, waste, and things of that nature find their way into the drains, so that special precautions should be taken, and arrangements made for cleaning them out, for inspection and accessibility. It is also important that the main blow down pipes from the boilers should not enter the drains, but should discharge into a large open sump and then overflow into the drains. With regard to chimneys, numerous designs are in use, but one design which deserves special mention is that of the Alphons Custodis Chimney Construction Co. It consists of hollow blocks, keyed with cement. The foundations required for engines, boilers, pumps, &c., are often elaborate so far as their requirements go, and it is usual to make these of concrete; the cable-ways and pipe trenches required should all be carefully shown on the plan, and undertaken at the time of the general building.

INSTITUTION OF ELECTRICAL ENGINEERS

THE following is the result of the ballot for new members on Thursday :—

As Members (2): Major W. B. Brown, R.E., War Office, Whitehall, S.W.; H. P. Gibbs, Chief Electrical Engineer to Government of Mysore, Bangalore, India.

As Associate Members (32): H. W. Arbuckle, Rifle Factory, Ishapur, near Calcutta: R. H. Bradbury, 49 Birmingham Street, Oldbury, near Birmingham; L. Burn, 13 Mayhill Road, Old Charlton; F. A. Cole, Sandymount, Helsby, near Warrington; E. Comerford, Abbots Grange, Chester; H. G. Cotsworth, Mining and Technical College, Wigan; R. W. J. Fletcher, 44 Garscabe Terrace, Edinburgh; J. K. Forrest, Tramway la Capital, Avenida de Mayo, 761, Buenos Aires; P. V. Gray, The Bombay Electric Supply and Tramways Co., Ltd., P.O. Box 192, Bombay; C. J. Grimes, c/o Port Commission, Calcutta; J. H. Harpin, 47 Temple Row, Birmingham; H. W. Hartnell, Corporation Electricity Department, Cheltenham; W. L. James, 22 Sutherland Avenue, Maida Vale, W.; J. Lloyd, Corporation Electricity Works, Norwich; C. H. Lydall, The Cleveland and Durham Electric Power, Ltd., Fylands Bridge Power Station, Bishop Auckland; J. J. McMahon, Clare Mount, Queen's Road, Cheetham Hill, Manchester; A. McPherson, 30 McCulloch Street, Pollockshields, Glasgow; A. W. Martin, Postal Telegraphs, Cambridge; W. L. Maxwell, Electrical Department, Central South African Railways, Pretoria; W. R. May, 134 Denmark Road, Lowestoft; W. F. Mitchell, Electricity Works, Dewar Place, Edinburgh; T. B. Naylor, c/o R. P. Wilson, Esq., 66 Victoria Street, S.W.; G. K. Paton, The North Wales Power Co., Ltd., Llanberis, R.S.O.; E. G. Phillips, "Heatherbrae," Priory Hill, Dartford, Kent; R. J. Roberts, Hopesay Rectory, Aston-on-Clun, R.S.O.; E. Rowarth, Battersea Polytechnic, S.W.; C. W. Smith, "Clandon," Woodside Road, Kingston-on-Thames; Professor W. Templeton, Ceylon Technical College, Colombo, Sandilands, M.A., B.Sc., Ceylon; S. W. Thomas, the Post Office, Sydney, New South Wales; B. Wiesengrund, Ph.D., 13 Woodside Park Gardens, North Finchley, N.; P. A. von Wildenrath, Box 36, Premier Diamond Mine, Transvaal; A. R. Woodhall, The Midland Engineering Co., 2 Victoria Square, Birmingham.

As Associates (4): Major J. Bruce-Kingsmill, R.A. (retired), Messrs. E. S. Hindley & Sons, Bourton, Dorset; H. Foulds, Faraday House, Southampton Row, W.C.; L. S. Simpson, Assistant Loco. Superintendent, Buenos Aires and Pacific Railway, Calle 25 de Mayo 277, Buenos Aires; W. B. Trafford, Sun Fire Office, Threadneedle Street, E.C.

As Students (133): F. Alexander, A. J. Anido, M. B. Baker, A. N. Balme, P. E. Bamford, J. T. Baring, L. Barney, R. H. Batson, H. G. Baxter, S. Baxter, C. W. Beak, A. G. Bower, R. A. S. Boyton, H. M. Bruton, L. G. Bulmer, J. H. P. Burchett, F. E. Burnett, M. N. Caird, R. W. Canning, E. G. D. Carr, R. A. Cartland, A. G. B. Chaldecott, T. W. Chalk, A. Collins, J. Conway, N. R. Corke, E. Crawshaw, G. G. Cree, A. W. Crompton, E. V. E. Crosse, S. P. Dass, J. J. de De Mesquita, A. E. Dent, T. A. F. Dixon, A. McLaren Doig, G. O. Earle, E. W. Eller, G. J. Farrelly, A. H. Finnis, F. G. Foote, R. Ford-Hutchinson, J. F. Forrest, K. P. Framjee; G. Franklin, F. W. Geoghegan, J. A. Gibson, L. B. Gilbert, C. M. Gillies, W. T. Golden, J. M. Goodall, A. G. Gow, M. F. Gower, H. P. Guy, J. Hacking, L. Harding, E. A. Hilton, J. H. N. Hingston, S. M. Hitchcock, W. R. C. Hockin, J. Hollingworth, B. W. Holman, P. E. Hosegood, E. F. James, E. Josephs, L. J. Jowit, S. Kay, R. E. Keelan, C. Kelley, A. F. Kelly, T. M. Klein, T. T. Kreiser, R. Larkworthy, W. R. Lewis, R. F. Long, D. W. Low, W. C. McCallum, E. S. McClintock, G. B. Manson, H. C. R. Martin, L. C. Martin, L. J. Matthews, C. Melbourne, E. A. Mills, R. M. Murché, R. E. Neale, V. W. Newman, J. P. G. Northcott, V. S. Padhye, R. G. Parrott, T. H. L. Paull, M. L. Peel, C. B. Penrose-Fitzgerald, T. C. Pettifor-Catchpool, M. Pitt, H. E. Poole, W. A. Prescott, A. Priestley, G. R. D. Prince, G. H. N. Reay, A. O. Roberts, W. L. A. Rogers, A. M. Rosa, C. Saxton, G. O. Scampton, A. R. Sharpe, R. A. Shiell, C. W. Short, E. Simkiss, H. J. Stenning, G. E. Stevenson, A. A. Stone, A. Stubbs, G. S. Terry, H. M. Thompson, C. P. Tufnell, E. J. Uhink, H. E. T. Vale, H. R. Viall, C. C. Villa, L. N. Vine, J. M. Walsh, F. G. Watermeyer, W. A. Watkins, H. G. Weaver, J. M. McGregor Whellens, P. F. R. White, S. N. C. Whitehead, W. H. Whitehouse, H. Williams, L. F. Willing, G. P. Willoughby, A. C. Yeates, G. E. Yonge.

Birmingham and District Electric Club.—Mr. E. C. R. Marks delivered his presidential address to the Birmingham and District Electric Club last Saturday. His subject was the relation of the Universities to technical training. It was, he said, of supreme importance that a University should recognise and endeavour to ally if not incorporate with itself such organisations as the municipal technical school. Manchester University has a faculty of technology, embracing not merely its own students, but those also at the Municipal School of Technology. The University of Liverpool in the faculty of arts had arranged for the preparation of students by evening classes of study for graduation in that faculty. He complained that their own University in particular gave no support to evening classes, and would officially recognise no students but those trained on its own premises. He was afraid the result might be that many young men who were worthy of being admitted as graduates of the University would go elsewhere for that encouragement and recognition they would gladly receive in their native city.

Nuisance from Brighton Corporation Motor Generator Station. On Thursday, in the Chancery Division of the High Court, Mr. Justice Joyce heard an action brought by the Rev. Edward Heath, Colonel Grove-Morris, and Mr. Frank Harold, who asked for an injunction to restrain the Brighton Corporation from working their North Road works so as to cause a nuisance and annoyance to the worshippers of St. Mary and St. Mary Magdalene churches, in Bread Street, Brighton. The allegation on the part of the plaintiffs was that the noise from the machinery disturbed the Rev. Mr. Heath while he was conducting the services, and it rendered it at all times impossible to hold classes and meetings. It was pleaded on behalf of the Corporation that their machinery was of the most modern type. They denied that there was either a nuisance or inconvenience, and relied upon their statutory powers, which they said they had exercised in a reasonable and proper manner. His lordship inquired if it was only the noise that was complained of. Mr. Hughes, K.C., for the plaintiffs, stated that the noise was still intolerable, despite the efforts of the Corporation to reduce it. It was of a very unpleasant and humming character. The case was continued on Friday and Saturday. The Rev. Mr. Heath stated that the noise varied greatly, but it could sometimes be heard above the organ and choir. He had been obliged to give up one of his classes, and also preach from the floor of the church instead of from the pulpit. Dr. Robert Hill Shaw said he was at St. Mary's Church on the previous Sunday. He got headache, owing to the noise. On Saturday Mr. Dinnick, estate agent and trustee of a number of houses in Bread Street, stated that owing to the nuisance from the Corporation works he had difficulty in obtaining the rents he formerly secured. The noise in the church and class-rooms rendered it difficult to read or write. Mr. Wharton, organist of St. Mary's, said the noise from the convertors resembled the sound of large humming tops. It varied slightly in different parts of the church. Cross-examined, witness said it could not honestly be stated that the noise was sufficiently loud to cause a nuisance to reasonable people. On Tuesday Mr. R. P. Wilson, consulting engineer, Westminster, gave evidence as to having inspected the church and Corporation works at Brighton in June and July last. He supported the plaintiffs' claim as to the noise which the electrical works created. A number of other witnesses who attend the church, and also live in the neighbourhood, spoke as to the noise, and the hearing was adjourned.

THE COST OF POWER PRODUCTION

MR. I. V. ROBINSON read a Paper on Tuesday last before the Institution of Engineers and Shipbuilders in Scotland on the cost of power production. The Paper consisted principally of a comparison of the estimated cost of power supply at a high load factor such as is obtained under the conditions of electro-chemical work from a water-power plant and from a gas-driven plant.

For purposes of comparison, a power station designed for a continuous output of 20,000 b.h.p. was taken and its capital cost was estimated, assuming (1) that waste gas from blast furnaces were available, and (2) that gas producers, and with them ammonia recovery plant, have to be provided.

As an up-to-date example of a water-power station, information was given of the cost of equipping two stations on the River Aveto in Italy, by the Societa Idroelettrica Ligure, Milan. Owing to the total head available being so great, it was decided to divide the fall between three power stations. The first station will generate 28,000 h.p., with a fall of 1,150 ft; the second, 17,500 h.p., with a fall of 625 ft.; and the third, 12,000 h.p., with a fall of 550 ft.

The total cost of the first and second stations is estimated to amount to £640,000, or slightly over £14 per horse-power developed.

This estimate includes the cost of the transmission line, transformers, and distribution system. For a comparison with a gas-power station, it was thought that the cost of the transmission line and transformers should be included. As the power station has to be built where the water is available, in the comparative cost must be included all expense entailed in bringing the power to the place where it is required. It is not necessary to include the distribution system, as for electro-chemical or electro-metallurgical work this would not be a very large item, such work usually being placed close to the power station or sub-station. It was assumed that £40,000 had been allowed for this item, reducing the capital cost to £600,000, or £13 4s. per h.p. developed. The electrical loss in the transmission line was taken as 10 per cent., so that then the capital cost per h.p. delivered is about £14 13s.

In a report recently issued, it is stated that the Mexican Light & Power Co. proposes the erection of a second water-power station to contain six units of 8,000 h.p. each. The total cost of the station containing in all 48,000 h.p. will be £417,000, or about £8 14s. per h.p. developed.

A Commission was appointed some time ago to report to the Canadian Government regarding the power obtainable in the Province of Ontario. The following details of the Cameron Rapids Development are abstracted from the fifth report of this Commission.

It is estimated that the Cameron Rapids are capable of developing 16,350 h.p., and that the bulk of this power would be transmitted to Port Arthur and Port William, 75 miles away. In estimating the total working costs, the Commission has allowed for the renewal of the so-called permanent works, such as dam, headworks, power-house, &c., in 40 years, and of the transmission and transformation plant in 15 to 30 years. Interest on capital has been allowed for at 4 per cent. The capital cost of the complete generating station, including all the headworks, &c., is estimated to be £168,300, or £10 6s. per h.p. developed.

The transmission line is estimated to cost £1,145 per mile; there will be a loss of 11·6 per cent.

The estimated annual generating and transmission expenses for the scheme are given as follows :—

Wages, labour, &c., £3,380; maintenance and repairs, £3,575; replacement fund, £3,450; administration, £1,000; interest at 4 per cent., £6,715; total generating expenses, £18,120. The generating expenses per h.p. per year work out at £1 2s. 3d.

The transmission expenses per mile are given as follows :—Interest, maintenance, repairs, and replacement fund, £63; right of way protection, £1 2s. 6d.; engineering and contingencies, £12 17s. 6d.; total, £77.

The total capital charges for 75 miles is thus :—£5,765, which, with the addition of £465 for patrol of line, gives the total transmission expenses as £6,230.

Taking the power transmitted as 14,450 h.p., the generating and transmission expenses per h.p. per year work out at £1 13s. 8d.

In the above estimate interest is allowed at 4 per cent. In the gas-engine estimate the interest allowed is 5 per cent. With the higher rate the generating expenses per h.p. per year would be £1 4s. 3d., and the generating and transmission expenses per h.p. per year would be £1 17s. 3d.

Some remarkable figures have been recently published by Professor S. P. Thomson regarding the cost of water-power used at Notodden for the Birkeland & Eyde nitrogen-fixation process. He states that the total costs per unit are 0·025d., and that they will be 0·0151d. at the new power station at Svaelgfos. The figures are equivalent to 13s. 7d. and 8s. 3d. per h.p. per year respectively. No information is given as to whether this includes replacement-fund charges, interest on capital, &c.

Various estimates of the cost of water-power have been made, and the cost per horse-power per year for a number of schemes is given in the following table :—

TOTAL COST PER HORSE-POWER PER YEAR.

Situation.	Price.	Remarks.
Svaelgfos, Norway.	£0 8 3	No transmission costs included. No information regarding capital charges, &c.
Notodden, Norway.	0 13 7	No transmission costs included. No information regarding capital charges, &c.
Cameron Rapids, Ontario.	1 2 3	Total generating costs. Interest 4 per cent.
Do. do.	1 4 3	Total generating costs. Interest 5 per cent.
Do. do.	1 13 8	Total generating and transmission costs. Interest 4 per cent.
Do. do.	1 17 3	Total generating and transmission costs. Interest 5 per cent.
Toronto, Canada.	2 17 9	Hydro-electric Power Commission's offer delivered to Corporation's boundary from Niagara.
Horahora Rapids, New Zealand.	3 0 0	Proposal of Waihi Gold Mining Co.
Montreal, Canada.	3 3 0	Average price obtained by Shawinigan Water and Power Co. for 19,000 h.p. delivered in Island of Montreal.
Do. do.	3 18 6	Montreal firm's contract with Shawinigan Water and Power Co. for 3,250 h.p.
El Oro Gold Mines, Mexico.	10 0 0	Purchase price of power transmitted 76 miles from Nexaca Station of Mexico Light and Power Co.

In considering the equipment of a gas-engine power station, engines were taken with double-acting cylinders 39½ in. in diameter by 43½ in. stroke (1,000 millimetres by 1,100 millimetres). A twin-tandem engine fitted with this size of cylinder would be capable of giving a continuous output of about 2,850 b.h.p. when running at 94 revolutions per minute. To ensure being on the safe side, the normal full load was taken at 2,500 b.h.p., eight engines would be installed for the full load of 20,000 b.h.p., and a ninth would be installed as a spare unit.

The foundations for a gas engine are generally more expensive than those required for a steam-turbine.

The approximate total cost of the complete power station is given in the following table :—

	Total Cost.	Cost per b.h.p.
Nine twin-tandem double-acting gas engines to develop 2,500 b.h.p. at 94 revolutions	£112,500	£5 12 6
Nine 50-cycle 5,000-volt three-phase alternators for direct-coupling to gas engines	£26,000	£1 6 0
Centrifugal-type gas-cleaning plant	£12,000	£0 12 0
Switchboard, motor-generators, and connections to alternators	£10,000	£0 10 0
Engine-house, 470 ft. by 80 ft., steel structure, brick-filled, with 20-ton crane	£24,000	£1 4 0
Foundations for gas engines and engine house about 14,000 cubic yards	£14,000	£0 14 0
Cooling towers for jacket-water 300,000 gallons per hour	£2,000	£0 2 0
Water pumps, air compressor, and reservoir for starting gas engine	£1,500	£0 1 6
Incidentals and supervision	£11,000	£0 11 0
	£213,000	£10 13 0

For a 20,000 b.h.p. gas-engine power station using producer gas, the equipment would not be altered, except that a gas-producing and ammonia-recovery plant would be substituted for the gas-cleaning plant. The capital cost of this plant complete with all producers, gas cleaners, ammonia-recovery towers, exhaust-gas-heated boilers for supplying steam required by producers would be about £75,000 or £3 15s. per b.h.p.

Digitized by Google

The total cost of the station would be £276,000 or £13 6s. per b.h.p., as compared with £10 15s. for the blast-furnace-gas station. There would be two coal-fired Lancashire boilers for providing steam when the plant is starting up from all standing, and if all boilers were of this type instead of the exhaust-gas-heated boiler, the total price would be reduced by about £4,000.

With a gas engine the working expenses are low owing to the high thermal efficiency, but the capital charges are higher than for steam-turbine plant, owing to the heavier initial expense. With water-power the second item constitutes the bulk of the total cost, owing to the generally very heavy initial cost and the fact that no fuel is required.

Some figures were given in a Paper read by Mr. L. Greiner, before the Liège Association of Engineers last March, regarding the working costs of Messrs. Cockerills' own central gas-power stations. In 1900 all electric power required in Messrs. Cockerills' works was generated by steam engines with a total capacity of 1,000 kilowatts. They gradually replaced their steam engines by gas engines, and by 1906 all the steam engines were removed, and they had gas-engines in use developing 5,700 kilowatts.

The output for 1906-7 was of 24,000,000 units with a load factor of 50 per cent. calculated upon a full year of 8,760 hours, and the working costs per b.h.p. per hour were 0·047d. With a higher load factor, the working costs per unit are decreased. For a load factor of 95 per cent. which may be attained in electro-chemical or electro-metallurgical works, the total working cost per b.h.p. per hour would be about 0·024d. On analysis of the working costs it was seen that they could be divided approximately as follows:—Labour, including engine attendants, generator and switchboard hands, &c., superintendence, &c., 45 per cent; lubrication, 20 per cent.; cleaning, upkeep, and repairs, 35 per cent. With a total cost per b.h.p. per hour of 0·024d., these three items amount to 0·108d., 0·0048d., and 0·0084d. respectively.

The fixed charges depend upon the useful life, the capital cost of the plant, and the interest to be paid upon this capital. Large gas engines have not been in use yet for a sufficient length of time to say from experience what useful life they will have. As this has a very great effect upon the fixed annual charges, three cases are taken, assming that the life is (1) 10 years, (2) 15 years, and (3) 20 years. It is necessary to allow only the same useful life to the alternators and foundations, as they might not be utilised for new gas-engines.

For the gas-cleaning plant, switchboard, motor-generators, &c., a useful life of 15 years may be taken. A 20 years' life is assumed for the water-pumps and air-compressors, but only 12 years for the cooling-towers, depending upon the quality of the timber used in their construction. The engine-house should last at least 40 years. For depreciation it has been assumed that a sinking fund would be formed, and that 3 per cent. compound interest could be obtained upon annual payments. For the engine-house a separate sinking fund should be formed owing to its life being so much longer than the other items. To obtain the period in which the sinking fund should mature, the cost of each item is multiplied by its allowable life, and the sum of these products is divided by the total capital cost. The annual payment to the sinking fund for the engine-house amounts to £310 per annum. For the remaining items in the blast-furnace station £189,000 has to be redeemed in 20 years for the longer life of the engine, &c. For the 15 years' life the equated period is 15·35 or, say, 15 years, and for the 10 years 11·3 or, say, 11 years. The annual payments are £6,820, £9,810, and £14,280. In addition to the sinking fund there is the interest on capital to be allowed at the rate of 5 per cent. per annum. The station is assumed to work at an average load of 19,000 b.h.p. for 8,760 hours per year, or at a load factor of 95 per cent. The output is then 166,000,000 b.h.p. hours per annum.

With this output the total annual working costs of the blast-furnace gas-engine station will be as follows:—

Item.	Life of plant. 20 years.	15 years.	10 years.
	£	£	£
Labour 166,000,000 at 0·108d. ...	7,470	7,470	7,420
Lubrication 166,000,000 at 0·0048d.	3,320	3,320	3,320
Cleaning and repairs 166,000,000 at 0·0084d	5,810	5,810	5,810
Works cost	£16,600	£16,600	£16,600
Sinking fund, engines, &c.	6,820	9,810	14,280
Do. house...	310	310	310
Interest	10,650	10,650	10,650
Total costs	£34,380	£37,370	£41,840
Cost per b.h.p. per year	£1 14 4	£1 17 4	£2 1 10

To estimate the cost of power generated by a gas-engine power station using producer gas, the extra net cost of the gas has to be added to the expenses previously indicated. From experience gained with several large producer plants, it appears that the total cost of producer gas for engines with a capacity of 20,000 b.h.p., working with a 95 per cent. load factor, will be as given in the following table. Coal has been taken at 7s. 6d. per ton, although an ordinary price for fuel of a suitable grade in the Glasgow district is 6s. per ton. The coal consumption per b.h.p. per hour has been assumed at 1·2 lb., or 1·6 lb. per kw. hour. This includes the raising of all steam required for the ammonia-recovery plant, &c. The yield of sulphate of ammonia per ton of fuel has been taken at 92 lb. This figure depends upon the composition of the coal and is a fair average value. The sale price of the sulphate of ammonia obtained from the gas has been assumed to be £11 per ton.

For the 10 years' life of the engine the sinking fund has to mature in 12 years, owing to the fact that a 15 years' life is allowed for the gas-producing and ammonia-recovery plant.

Labour at the gas plant	£5,300
Acid, stores, repairs, &c.	9,300
Water	770
Fuel—89,000 tons at 7s. 6d. per ton ...	33,375
	£48,745
Less 3,660 tons of ammonium sulphate at £11 per ton	40,260
Nett cost of gas ...	£8485

	Life of plant. 20 years.	15 years.	10 years.
	£	£	£
Works cost (excluding fuel)	16,600	16,600	16,600
Nett cost of gas...	8,485	8,485	8,485
	£25,085	£25,085	£25,085
Sinking fund, engines, &c.	9,200	13,480	17,700
Do. house...	310	310	310
Interest	13,800	13,800	13,800
	£48,395	£52,675	£56,895
Cost per b.h.p. per year	£2 8 5	£2 12 8	£2 16 11

From this comparison it appears that power generated from blast-furnace gases costs about the same as water power, when the capital cost of the generating station, with or without transmission lines as may be required, is about £18 per h.p. delivered at the consumers' boundary Investigation shows, however, that the majority of water-power plants are estimated to cost more than this figure.

Power from gas engines using blast-furnace gas is, therefore, worthy of more attention than it has received up to the present time in Great Britain. During 1905 the various Scotch blast furnaces turned out 850,000 tons of pig iron. With this output the spare power would be about 71,000 h.p. on the assumption that the works are equipped with modern gas-blowing engines, &c. If this power were used for the manufacture of calcium carbide, aluminium, or nitrogenous manures from atmospheric nitrogen, it would be possible to get a return of at least £2 per h.p. per annum. There is thus an annual loss in the Scotch blast furnaces only of upwards of £140,000. To harness this power the capital cost would be about £750,000. A return of £2 per h.p. per year would give upwards of 18 per cent. on this capital expenditure in addition to the 5 per cent. interest allowed in estimating the cost of the power.

Institution Leeds Local Section.—A smoking concert will be held on Thursday, February 6th, at the Hotel Metropole, Leeds, at 8 p.m.

A Large Sub-station Battery.—One of the features of the Albula-Zurich power scheme is to be the provision of a battery of very considerable size, intended to act as a stand-by for the Zurich tramway system in event of interruption in the supply from the Albula station, about 130 kilometres distant. In this scheme, according to *L'Electricien*, two independent transmission lines are provided, one on each side of the lake, to the sub-station of Letten. At this sub-station a certain amount of reserve plant will be installed for use in event of breakdown or shortage of power at the main station. The chief object of the battery, which can furnish an output of 4,700 h.p. for fifteen minutes, is to carry on the supply while the reserve plant is being started up; but it can also be employed as a buffer battery to equalise the load. The cells are of the "Olten" type, and the battery is said to be the largest in Switzerland. As the system is alternating an automatically controlled motor generator is used for charging and discharging.

THE NORTHAMPTON INSTITUTE, ELECTRICAL ENGINEERING DEPARTMENT

THE Electrical Engineering Department of the Northampton Institute is designed so that the students may have not only theoretical but also practical work in connection with their studies. The department is divided into three sections for instruction, which comprise junior, intermediate, and advanced classes, and the whole course of lectures covers a period of four years for day students and five years for evening students.

The senior engineering laboratory in the basement is divided into two sections: the generator room, and a meter-testing and standardising room. In the main laboratory are a number of small machines, both continuous- and alternating-current dynamos, and motors, upon which the students are allowed to practise starting, stopping, regulating, paralleling, synchronising, &c. The department is arranged so that the students can see exactly what happens in all their experiments. All the machines are connected by mercury distribution boards, in such a way that any machine or combination of machines may be simply and easily connected to the main distribution board, without altering the leads on the dynamos themselves. Machines brought in for testing can easily be placed in any part of the laboratory, as lines of sliding rails are provided. There is a motor generator, the generator of which has been manufactured entirely in the workshops of the department on the premises. The generator is three phase, and each set of coils is double wound, which enables it to be run either in series or in parallel. The field magnets are wound in sections on the Heyland principle, each having six slots and wave-form winding; each slot is independent of the others, and the whole can be short circuited by means of supplementary slip rings.

Each machine in the laboratory has its own ammeter and voltmeter, and regulating resistance, which are fixed, and has its own speed indicator. There is also a stroboscope for determining exactly the speed of each set. This instrument consists of a tuning fork, which has slits and shutters on the prongs, and when the tuning fork is vibrating light passes through the slits. On the end of the shaft of the machine is placed a disc in which a square is surrounded by a pentagon and a hexagon. The square appears for speeds between 1,500 and 3,000 revs., double for 750 and 2,250 revs., and triple for 500, 1,000, 2,000, and 2,500 r.p.m. A single pentagon appears at speeds of 1,200, 2,400, 3,600, and double for 600, 1,800, 3,000, and triple for 400, 800, 1,600, 2,000, 2,800, 3,200. The hexagon appears single at 1,000, 2,000, 3,000, and double for 500, 1,500, and 2,500, triple for 333·3, 666·7, 1,333, 1,667, 2,333, 2,667 revs. per min.

The plant in this testing laboratory contains a specimen of nearly all the best known types of motors and generators. The generator and motor-test bed has been arranged for the testing of either direct-current or alternating-current machines, and consists of a Westinghouse 10 h.p. generator running at speeds from 750 to 1,000 r.p.m. This machine is supported on ball bearings and knife edges, and has a telescopic shaft and an ordinary chuck coupling, so that any motor can be easily connected to it. A special method for getting the machines into alignment is provided. The motor is placed on rails on an iron table, which can be raised or lowered by means of screw gearing. The power supplied to the machines under test is measured by weighing the torque at the end of one of the two levers, a two-pound weight balanced at 1,000 r.p.m. being equivalent to one horse-power. The switchboard was constructed to the specifications of the professors of the Institute. The main and shunt terminals of the generator are connected to this. On this board the cables from the direct-current machines are connected by means of two single-pole switches, and by means of a reversing switch the excitation of the swinging generator is obtained from the negative pole switch. Reversing switches are also provided. The positive pole of the dynamo is connected through a short-circuiting switch, and overload circuit breaker and ammeter, to the centre of the positive main switch, which also is of the throw-over type. The right-hand contact is connected to the positive main and the left-hand to the negative terminal of the armature. Over the raising table, on which motors to be tested are placed, there is another switchboard, which is made up of eight switches and four terminal contacts. Six of the switches connect the terminals to any of the supply, either one, two, or three phase, for which the laboratory is specially wired. The other two terminals are connected to the direct-current supply. A voltmeter is provided for paralleling the generator, which is run up to speed by the motor under test, and then paralleled on the supply mains. A motor under test can be loaded either with the generator in parallel, or can be loaded up on resistance.

In this laboratory there is also provided a transformer station in the form of a table, which enables the transformers to be tested without danger to the students. It consists of a special bench, in which the transformers are enclosed in glass-fronted cases, and thus the windings and general construction are visible to the students without being readily accessible. There is at one end of this table a Kolben converter, which supplies power at 2,000 volts, and is on the three-phase system. The other transformers, which range from two to four kilowatts, can be connected to the converter and then transform down from 2,000–100 volts. The transformers can be loaded up by means of resistances, or can be directly connected to the main supply of the building. For taking the readings on these tests, two wattmeters are provided, which read either on the single or three-phase supply, and on the low- or high-tension sides. There is also in this department a special Ferranti alternator, with contact makers in connection with an oscillograph, which is also connected to an Addenbrooke electrostatic voltmeter, so that wave forms can be correctly determined.

The adjoining department is the standardising laboratory, just outside the machine room. This laboratory contains a long bench, upon which are mounted the secondary standards for current and potential difference. There are four Siemens dynamometers, and also a battery of three cells, which is capable of being used either in series or parallel, and a converter transforming from 200–5 volts, and capable of dealing with currents, either continuous or alternating, up to 400 amperes. Regulation is obtained by graduated Eureka wire resistances and connectors sliding in mercury trough resistances. Cables run from the testing bench to the main switchboard, so that any ammeter in the laboratory can easily be tested from its permanent situation. On this bench there is also a Kelvin electrostatic instrument, a Weston standard voltmeter, and a potentiometer, for standards for testing direct- and alternating-current potential difference at various voltages. There is a pair of voltmeter checking leads running round the laboratory for the testing of voltmeters, which can be fixed to the battens in the same manner as the ammeters, and each voltmeter is provided with a two-way switch, by means of which the voltmeter can instantly be switched off the testing machine and on to the standard checking leads. Each ammeter and voltmeter has at its side a small case, in which a card recording the number of the meter, and the amount of error on both alternating and direct currents.

In the junior laboratory there is a complete set of simple instruments, and specimens of all kinds of batteries and small motors, &c., with which the students are allowed to experiment; simple winding of motors and dynamos, and the construction of resistances and controllers and their general action are taught in this laboratory. In the intermediate laboratory more heavy machinery is provided, and motors up to 5 h.p. are supplied, of various makes, and the students in this department perform all kinds of experiments. The Institute provides a number of cards, on which different experiments are defined, and the students are each given one of these, and are expected to conduct the whole of the work themselves, doing all the necessary wiring and connecting up.

In the senior laboratory there are a number of tables on which different testing apparatus is set out, and which enables all kinds of instruments to be tested. The first of these tables is equipped with a standard Anthony-pattern bridge, with various shunts and cell regulators, connected to a Kelvin galvanometer with coils of various resistances. The bridge winding is of low temperature wire. The second table is provided with a Carey-Foster bridge, for the standardising of resistance coils, and for the testing of low resistances as used in potentiometer work. Oil baths for keeping the coils at any desired temperatures are electrically heated. The third table is arranged for testing insulations, &c. Here there is a 100,000-ohm Kelvin galvanometer of high insulation, and there is a secondary cell battery, consisting of 300 small cells, and from which 600 volts can be obtained. The cables to be tested are of various lengths and makes, and are contained in circular tanks. The fourth table is laid out for testing extra high insulations, by fall of potential theories. An Ayrton-Mather electrometer and small tanks containing various types of insulators are used for these tests. The fifth table is used for capacity measurements, and is arranged with various kinds of keys, a standard condenser, and a ballastic galvanometer, by Nalder Bros., of 10,000 ohms. A universal shunt, by Sullivan,

Digitized by Google

enables all kinds of capacity tests to be made. No. 6 table is for induction instruments and measurements, and the set consists of a Wheatstone bridge, to which are connected variable and fixed standards of self-induction, and also a motor secchometer. On No. 7 table there is a Crompton standard potentiometer, which is used in connection with a Crompton moving coil galvanometer, and Board of Trade and Carhart cells are used for standardisation, and measurements can be made up to 750 volts, which pressure is obtained from the cells in the Institute. Tables 8 and 9 are used for measuring currents, and Kelvin deca- and centi-ampere balances, and regulating resistances are provided. Copper and silver voltameters, with a balance for standardising currents, are provided. Other tables are provided with iron testing and conductivity apparatus. For the testing of iron the experiments are carried on, in the ring and yoke methods, by magnometer. In the electrochemical laboratory all kinds of experiments are carried out. A large vacuum tube with adjustable electrodes is used for determining the various amalgams of the rarer metals used for the filaments of electric lamps, &c. There is also a complete laboratory for determining the candle-power of incandescent lamps. We are indebted to the Principal, Dr. R. Mullineux Walmsley, Dr. C. V. Drysdale, and Mr. Jolle for the facilities which they have given us for the compilation of this article.

"THE BABES IN THE WOOD"

IN this year's Drury Lane pantomime, "The Babes in the Wood," some highly ingenious and pleasing electrical effects are produced. One of these is in the "firework act." A huge imitation rocket is brought on to the stage, and the top, consisting of an ordinary squib, is lighted. The usual "fizzing" ensues, and at the instant when the squib explodes the switches of all stage circuits are opened; this is intended to represent the ascent of the rocket. Then, descending through the darkness, are seen half a dozen of the familiar coloured lights which make their appearance when a rocket explodes in mid air. These coloured lights are really electric lamps, lowered slowly and cautiously from the flies. At a given signal they are extinguished, and quickly drawn out of sight, upon which the stage circuit switches are once more closed.

Another delightful effect is that of the rising sun. This piece of apparatus consists of a shallow drum, with calico in place of the usual skin, while between the two ends or "heads" are several incandescent electric lamps of various colours, from ruby to clear, wired on a number of different circuits. The stage lights, which have previously been almost extinguished, are gradually brought up on the dimmers until a faint glow suffuses the stage. Then the sun, which measures 6 ft. 6 in. in diameter, is gradually raised from the stage behind a forest and cloud scene, only the ruby lamps being on. At this point only the upper edge of the sun's disc can be seen from the front, and it appears blood red. As it is raised it apparently passes through clouds—which are really painted on the back cloth—while at the same time some of the ruby lamps are switched out and amber lamps are switched on. Simultaneously the stage lights are brought still further up on the dimmers. This process is continued until the sun appears to be of a brilliant golden hue, and the stage lamps are then brought up to full brightness. The stage is then flooded in warm sunshine, and the effect is complete.

Another pretty scene is that in which about a dozen members of the chorus perform a moonlight dance. Each dancer is provided with a wire ring, a foot in diameter, around which are fastened 16 lamps, each taking 1½ amperes at 8 volts. The ring and lamps are covered with a blue fabric, and the whole contrivance is very aptly called a "halo." The lamps are supplied from portable accumulators carried in indiarubber bags and suspended from the dancer's shoulders at the back. A small tumbler switch, carried in the hand, completes the equipment.

In another scene, which depicts the search for the "Babes," some three dozen electric torches, of the familiar type, are employed. These, carried to and fro, on a dark stage, produce a very pleasing effect.

The above are only a few of the applications of electric lighting in the "Babes in the Wood," what are technically known as the "big scenes" being on the usual lavish and magnificent scale.

Mr. H. Mather, the theatre electrician, is to be congratulated on the success which has attended his efforts, and we are indebted to him, as well as to the management, for his courtesy in enabling our representative to obtain the above details.

While referring to Drury Lane Theatre, we may take the opportunity of congratulating the management on the fact that the old system of gas heating has been at last banished for ever. For some time after elaborate precautions had been taken to guard against fire risk, the old gas radiators were retained, having a bunsen flame clearly visible from the outside. Everything inflammable was removed; iron was substituted for wood wherever possible, and the ancient wiring in casing which had done duty for so many years was reconstructed throughout in screwed steel barrel. And still the gas heaters flourished. At last, however, they have been replaced by an admirable system of heating and ventilating, electrically driven throughout. The stage plant consists of a large washing drum, measuring about 6 ft. by 6 ft. This drum is covered with a hair matting, and the lower part of its periphery dips into a large tank of water; it is driven by a 1½-h.p. Taunton motor, and its surface is therefore kept continually in contact with fresh water. Air is drawn in through the interstices of the saturated matting by a 10-h.p. electrically driven Sirocco fan, situated at the end of the drum, remote from the entrance to the chamber. The air which has thus been cleaned is passed through a tunnel, and comes in contact with a nest of about 120 steam pipes, arranged vertically. From these pipes it enters a large brick tunnel, which passes completely round the stage. At intervals, galvanised iron ducts lead off from the tunnel to points where it is desired to have an influx of warm air. The exits of the ducts consist of gratings with circular holes. A row of such gratings has been arranged between the curtain and the footlights, so that when the former is raised, occupants of the stalls are not now treated to the chilly blast which used to follow the conclusion of the overture.

Above the "gridiron" is an extraction consisting of a Sirocco fan, driven by a 10-h.p. motor, so that the warmth of the stage can be regulated to any desired degree. Further regulation can be obtained by means of the valves with which all the air ducts are provided.

For the front of the house a similar washing plant has been installed, while the extractor consists of a 15-h.p. electrically driven fan, situated immediately above the sun burner.

All the controllers, supplied by the Electric Ordnance & Accessories, Ltd., are situated under the stage, and are provided with the usual iron cases; the wiring has been carried out in screwed steel barrel.

In summer-time the entire plant is used for the introduction of cooled air into the theatre, and the extraction of heated and vitiated air. This change is effected simply by passing the washed air through open doorways instead of through the nest of heated steam-pipes.

Steam is generated by a Paxton boiler of the locomotive type, the pressure being 65 lb. per sq. in., and the evaporative capacity about 1,800 lb. per hour. Feed water is obtained from the hot well by means of a steam feed-pump and a Penberthy injector. This boiler is also employed for heating the scene-painting room, which is provided with 1,000 ft. of steam barrel and four Geipel steam-traps.

The B.T.-H. Petrol-Electric Omnibus.—An account of a 10,000 mile trial of a Wolsely motor-omnibus fitted with the B.T.-H. electrical transmission gear, just completed in the service of the London General Omnibus Co., is given in the *Railway Times*. As was to be expected for a new departure of this nature, minor defects became apparent in the course of the trial. These were rectified, and it is stated that the last 3,700 miles were covered without adjustments being necessary. The actual mileage covered was 10,480 out of a possible 13,390 miles. It must be remembered that no spares were held in London, and that considerable time was occupied in investigating the defects that occurred instead of getting the vehicle on the road again as soon as possible, as would have been the case were it an ordinary vehicle in service. The consumption of petrol is given as 4·8 miles to the gallon over the whole trial. This is said to be slightly better than the consumption with the gear-driven 'buses running over the same route. This vehicle was always exceedingly quiet, and, although it has run upwards of 15,000 miles, it has not become any more noisy. After the trial the chassis was stripped for inspection, and the electrical equipment was found to be in excellent condition. An illustrated description of the British Thomson-Houston petrol electric system appeared in ELECTRICAL ENGINEERING, Vol I., p. 463.

THE HEAT CONDUCTIVITY OF IRON STAMPINGS

THE object of the research described in the Paper read yesterday by Mr. T. M. Barlow before the Birmingham Local Section of the Institution of Electrical Engineers was to determine the heat conductivity of assembled insulated iron stampings, first in a direction parallel to the plane of their surfaces, and second in a direction at right angles to their surface through both iron and paper.

The theory of heat conduction was briefly considered, and, considering cylindrical surfaces, such as shown in Fig. 1, of a length, l, separated by a medium of heat conductivity, K, it was shown that difference of temperature, θ, between two points could be expressed as

$$\theta = \frac{1}{K}\frac{Q}{2\pi l} \cdot \log_e\left(1 + \frac{x}{r}\right)$$

From this formula the values of K (which is numerically equal to the quantity of heat which flows per unit time through unit

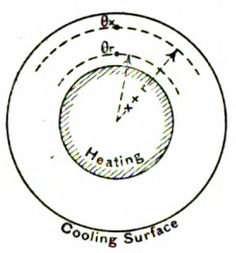

FIG. 1.

area of a plate of unit thickness having unit difference of temperature between its faces) for iron stampings, both in the direction parallel to the plane surface of the stampings and across the iron and paper at right angles to the surface, were calculated.

If K_a be the heat conduction coefficient for iron laminations in a direction parallel to the surface of one stamping, and K_b in a direction at right angles to this surface, and if C equals the ratio of the sides of two square surfaces, one being the edge surface of a packet of stampings and the other being the plane surface of the outside stamping of the packet, and if both these surfaces are made to dissipate the same amount of heat, *i.e.*, equal cooling, then—

$$C = \sqrt{\frac{K_a}{K_b}}.$$

To obviate the difficulty of calculating the heat leakage if the iron stampings were heated on one side, a cylinder built up of stampings was used, being heated on the inside edge and cooled on the outside (see Fig. 2). This was built up of stator

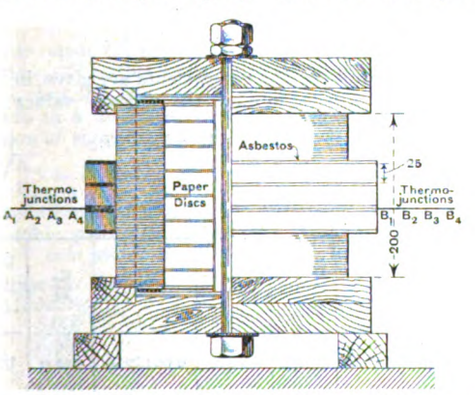

FIG. 2.—SECTION AND ELEVATION OF APPARATUS.

stampings made by Messrs. Sankey & Co., Bilston, 0·0345 cm. thick, and insulated with a preparation known as "Insuline." The plates were firmly clamped together, and the slots wound with twenty turns per slot of D.C.C. copper wire. The slots were insulated with paper tubes built up with shellac varnish. The thermo-junctions for the core were fixed between two fine sheets of condenser paper cut to the same shape as the stampings, the two leads of each junction being carefully brought out so that there was no fear of short circuit. The stampings were clamped together between two wooden rings, insulated with asbestos from the iron stampings. To prevent the iron bolt from getting hot and so allowing the nut and head to dissipate heat, the air inside was divided off into sections, so as to localise the heat currents by means of discs of paper. The bolt was also shielded by a paper tube. The top and bottom of the core were insulated also with asbestos sheet, cord, and cotton waste. These precautions ensured that practically all the power supplied to the windings would be dissipated in heat from the outside edge surface of the stampings.

For the second part of the work, *i.e.*, the measurement of the heat conductivity across iron and paper, iron strip was wound over the outside of the cylindrical core, each layer being interleaved with paper. The strip was 2·5 × 0·05 cms., and was of

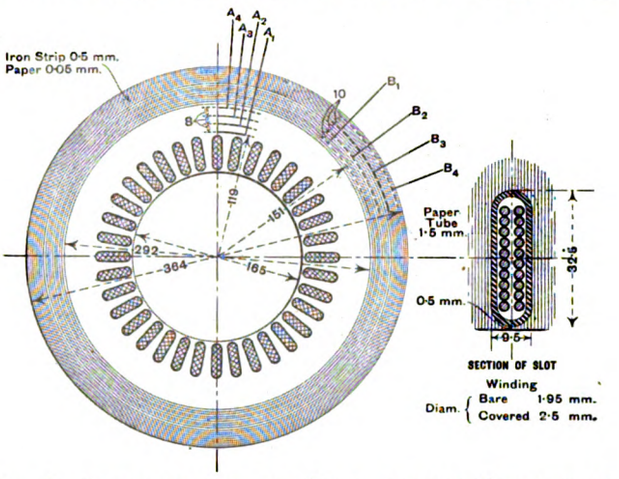

FIG. 3.—SECTION OF CORE AND STRIP, SHOWING POSITIONS OF THERMO-JUNCTIONS (ALL DIMENSIONS IN MILLIMETRES).

best soft steel of bluish colour. The paper was 0·005 cm. thick. Three coils were wound, the thermo-junctions being placed at suitable intervals in the centre one, the two outside rings acting as guard rings. The coils were insulated with asbestos sheet from each other, and the edges of the two outside coils were also insulated from the air with asbestos sheet rings.

The position and method of carrying away the leads of the thermo-junctions are shown in Fig. 3. In the core A_1, A_2, A_3, A_4 were placed 8 mm. apart. In the strip B_1, B_2, B_3, B_4 were 10 mm. apart, giving a total distance between A_1 and A_4, B_1

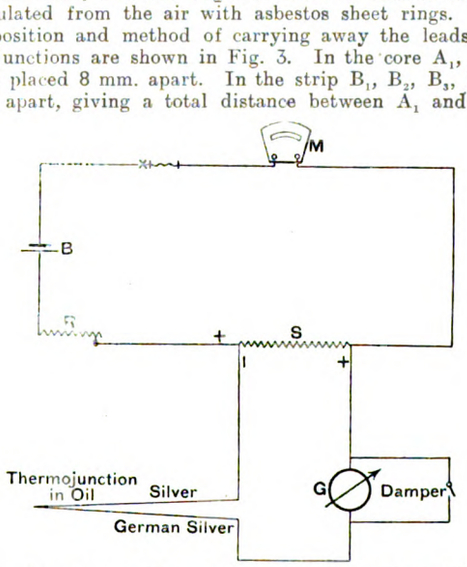

FIG. 4.—DIAGRAM OF CONNECTIONS (THERMO-JUNCTION TEST).

B. Two-volt accumulator.
R. Variable resistance for regulation.

and B_4, of 2·4 cms. and 3 cms. respectively. After the strip had been wound on it was found that A_3 and B_3 had become short-circuited or broken. As this could not be remedied without dismantling the whole apparatus, readings were only taken from the six remaining thermo-junctions, these being quite sufficient for calculating the results required.

The measurement of the temperature by electrical resistance thermometers was considered impracticable.

As the temperature was only to vary from 15–80° C., a new combination of metals was tried for a thermo-junction, and was found to give a straight line between the above limits. The positive wire was of No. 40 German silver silk covered,

Digitized by Google

and a No. 32 pure silver wire bare was used as the negative. The actual junction was made by twisting the ends for about 0·3 cm., dipping in silver solder, and then flattening by light taps.

A series of tests was carried out on two of the thermo-junctions used. The elements were first heated in an oil bath to about 90° C. and allowed to cool slowly. The temperature of the oil, *i.e.*, the hot junction, and the temperature of the cold junction were measured by delicate mercury thermometers. The micro-voltage was measured by a potentiometer method. The diagram of connections is shown in Fig. 4. From these

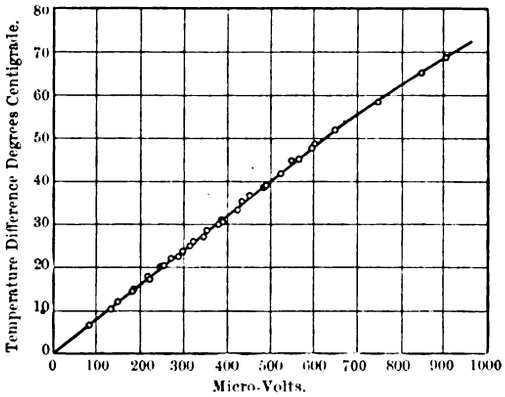

FIG. 5.—TESTS ON THERMO-JUNCTIONS A_1 AND B_1.

tests the micro-voltage per 1° C. rise of temperature was found to be 12·73. Other junctions tested gave points on the curve in Fig. 5, so this figure was accepted as correct for temperature measurement.

The experiments were conducted in a room kept as near at as uniform a temperature as possible, so that the temperature of the cold junctions would remain constant. The core was heated up for eighteen hours by passing current through the coils. Connection was then made through one of the junctions, the shunt, and the galvanometer. The galvanometer mirror was then brought to zero by passing a current through the shunt in the opposite direction. This was very finely regulated, giving the current through the shunt, and so the micro-volts for any particular junction, hence the temperature of the iron at the point where that junction was fixed.

The micro-volts A_1, A_4 were first taken. Then B_1 and B_4, and finally A_2 and B_2. The whole set of readings was repeated three times and the average taken if there was any slight variation. The instruments were all millivolt-ammeters by Siemens & Halske, and were used with suitable shunts. The main resistance, carefully calibrated, was made by the same firm, and was of 0·0005 manganin. The regulating resistances were of the ordinary wire type of 42 ohms and 31·5 ohms respectively. A carbon resistance, which was always kept tight during the tests, was placed in the circuit for final adjustment. A diagram of connections is shown in Fig. 6.

The instruments used for recording the watts supplied were a voltmeter, to read from 0–15 volts, and an ammeter, to read from 0–15 amperes.

The author then proceeds to a theoretical calculation of the conduction coefficient across iron and paper from the known values for iron, paper, and air, which, taking the proportion of the thickness of the iron, paper, and very small layers of

air between as 0·05 cm., 0·005 cm., and 0·00125 cm. respectively, and the following are values of K used for iron, paper, and air (C.G.S. Centigrade units) :—Iron, 0·152; paper, 0·0003; air, 0·0000528 (values obtained from the works of Hall, Lees and Compan), works out as 0·00138.

The constants for the experiment in formula for temperature difference are then worked out for the formula

$$\theta = \frac{1}{K} \cdot \frac{Q}{2\pi l} \log_e \left(1 + \frac{x}{r}\right)$$

The complete results of the experiments are given in Table I., from which it will be seen that the average values obtained are :—

$$K_a = 0{\cdot}1405 \text{ and } K_b = 0{\cdot}00137.$$

This gives an average value of C of 10·1. Hence the ratio of sides of square edge and plate surfaces of iron stampings for equal cooling averages about 10. In actual practice the pressure on the stampings would be slightly more than that used in the experiment. This would lower the value of C by raising K_b a little.

The temperature-drop curves shown in Fig. 7 are for Test 6.

A method of calculation of curves for temperature rise in iron stampings from the values of K and C is then given.

Consider the case of a packet of iron stampings heated internally by (we may suppose) hysteresis and eddy currents. Let the temperature at a mid-point distance t from either

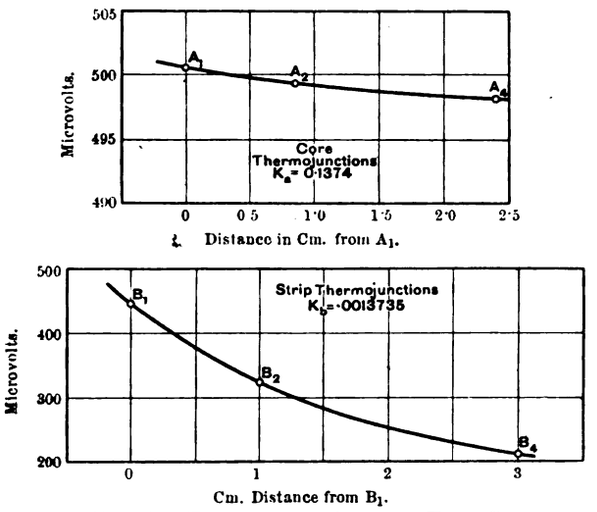

FIG. 7.—TEMPERATURE CURVES (TEST 6).

face be θ_2, and θ_1 be temperature at outside surface, then $\theta = \theta_2 - \theta_1$.

Consider an element distance x from ab having a cross-section of 1 sq. cm. The element has a temperature difference of $d\theta$ and a volume of x c.cms. Then heat transferred between $x=0$ and $x=x$ is $\frac{d\theta}{dx}$. K_a after a steady state has been reached.

But the heat transferred equals the heat generated. Also the heat generated in x c.cms. $= f(x) = \lambda x$.

$$\therefore \frac{d\theta}{dx} K_a = \lambda x$$

where λ = calories per cubic centimetre—

$$\therefore \frac{d\theta}{dx} = \frac{\lambda x}{K_a}.$$

Integrating—

$$\left[\theta\right]_{\theta_1}^{\theta_2} = \left(\frac{\lambda x^2}{2K_a}\right)_0^t \quad \therefore \theta = \frac{\lambda t^2}{2K_a}.$$

λ depends upon the induction frequency and thickness of the iron plates. Therefore curves can be drawn for various inductions showing the temperature gradient for any length of heat path, both in a direction parallel to the iron stampings, and in a direction at right angles—that is, across iron and paper, since $C = \sqrt{\frac{K_a}{K_b}}$ is known. The value of P_i—*i.e.*, watts lost per kilogramme corresponding to any particular induction—are taken from a table published by Sankey & Sons, Bilston, for their "Stalloy" iron stampings 0·35 mm. at 50 ∽ given below.

B (lines per cm.²) (Induction).	P_i (Watts lost per Kg.).
5,000	0·64
6,000	0·84
7,000	1·08
8,000	1·32
9,000	1·56
10,000	1·87
11,000	2·15

From the table we can obtain the loss in watts per kg. = to P_i.

This reduced to calories per cubic centimetre $= \lambda = \frac{P_i}{540}$.

$$\therefore \theta = \frac{P_i}{540} \cdot \frac{t^2}{2K_a}.$$

K_a average value = 0·1405—

$$\therefore \theta = \frac{P_i t^2}{152}.$$

The curves (Fig. 9) are applicable to the flow of heat across iron and paper by using the top scale, which is $\frac{1}{10}$ the bottom scale, C being taken equal to 10.

After the completion of tests as above the iron strip and paper were removed. The core was then heated up to various degrees and the temperature noted by means of the thermo-junctions. Two series of tests were conducted: (1) still air cooling, (2) moderate blast cooling. The latter was obtained by sending a blast from an ordinary ventilating fan round the core.

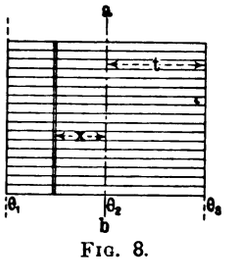

FIG. 8.

The results of these additional experiments are in Fig. 10, which is taken from an appendix to the Paper, together with the theoretical hyperbolas near to which they lie.

It will be noticed that for still air the theoretical hyperbola does not lie very well on the curve obtained by experiment. This is due to the convection currents which are set up in the still air by the dissipation of the heat. In the case of the strong air blast these have no effect. Hence the theoretical hyperbola, $T\sigma = 300$, more closely approximates to the actual curve obtained.

The main conclusion to be drawn from the values of the heat conductivities of iron insulated stampings found for a heat path (1) in a direction in the same plane as the plate surface of the stampings, and (2) in a direction at right angles to the stampings (across iron and paper), is the importance which must be given to the amount of edge surface of the stampings of a laminated iron core exposed to the cooling medium, either air or oil.

It is seen from Fig. 9, which may be drawn for any iron stampings of which the hysteresis and eddy current losses are

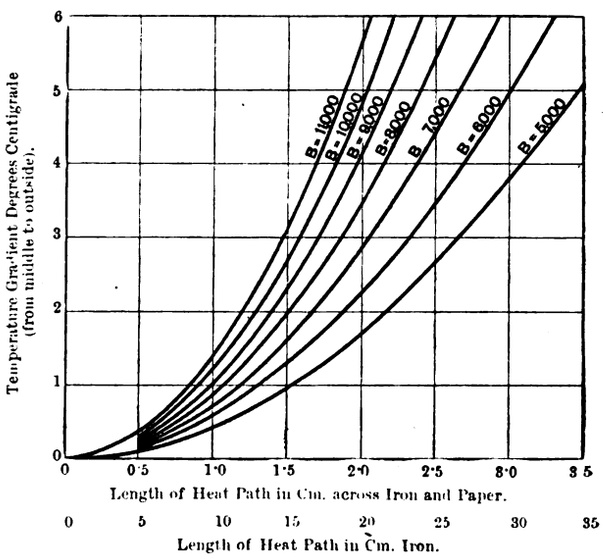

FIG. 9.—TEMPERATURE CURVES FOR "STALLOY" IRON.

known, that the temperature gradient will be almost a straight line in a direction with the plane of the stampings. Thus the internal temperature of the core is quickly reduced if the method of cooling employed, either air or oil, is used on this edge surface. On the other hand, if the iron laminated core is only cooled on the plate surface, the temperature will rise, comparatively, very rapidly as the core is penetrated across the iron and paper. This rise amounts to as much as 5° C. for a distance of 2 cms. for an induction of 10,000 lines per cm.² at 50 ∽ in the iron for which the curves are plotted. The effect of this steep temperature gradient in an iron core thus cooled is the increase of the hysteresis loss in the centre portion due to the decrease of the permeability of the iron with the rise of temperature. Also for any iron rectangular laminated core, which is heated internally, from the values of $C = \sqrt{\frac{K_a}{K_b}}$ (the ratio of the linear dimensions of the sides of the core, *i.e.* edge side to plate side) for the most efficient cooling must equal 1 : 10. This ratio is somewhat higher than is used at present in common practice, the figure averaging about 1 : 6 for

Digitized by Google

small armature cores and transformers, and 1 : 7·5 for large cores. Further, dealing with the question of the ventilation of direct-current armatures, it will be noticed that the ventilating ducts between the packets of iron stampings are not so useful on account of the extra plate surface exposed to the cooling draught induced, but act more as an outlet for the air inside the centre space of the armature, which has been heated in cooling the inside edge surface and so the internal parts of the core. This also applies to the ducts in large transformer cores cooled by a direct air blast. In connection

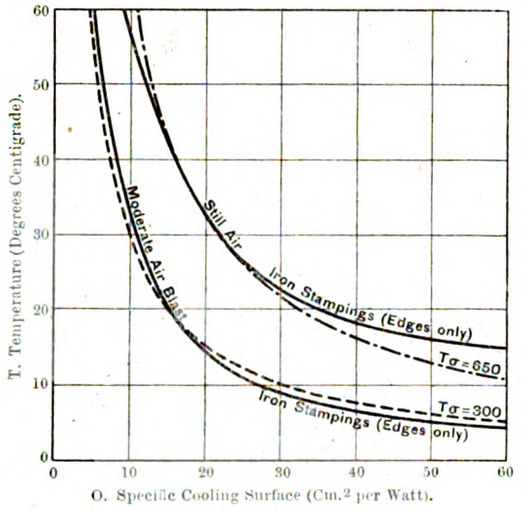

FIG. 10.—COOLING CURVES.

with the few tests for cooling coefficients for iron cores, these formulæ may be used for the temperature rise (surface) of the iron core of a transformer, where the effective plate surface for cooling, in comparison with the edge surface, can be neglected. Values of the coefficient may be approximated for different rates of air cooling, but further work is necessary on this part of the work before any definite conclusion can be inferred.

In conclusion, the author expresses his thanks to Professor Kapp, of the Electrical Department of the University of Birmingham, at whose instigation the research was carried out, for the facilities afforded.

Alleged Damage to Electric Cables.—Sitting as a Divisional Court in the King's Bench Division of the High Court, Mr. Justice Phillimore and Mr. Justice Walton had before them on Thursday the case of the Westminster Electric Supply Corporation v. The London County Council, which came up on the appeal of the plaintiffs from the judgment of the Westminster County Court judge.

Mr. A. B. Shaw represented the plaintiffs, and Mr. Horace Avory, K.C., and Mr. Radcliffe Cousins appeared for the defendant council.

Mr. Shaw, in opening plaintiffs' case, stated that the action was brought to recover damages said to have been caused by the Council's servants to their electric cables in the borough of Westminster. The plaintiffs had some trouble with their cables in October last, a short circuit manifesting itself. They traced it to Greycoat Place, Westminster, where in the previous February the defendant Council had constructed a fire station, and on opening the ground they found that the casing had been injured, letting in the damp, and eventually destroying the insulation. When the action came before the County Court judge, the defendant Council pleaded the Public Authorities Protection Act, maintaining that inasmuch as the writ was not issued within six months of the cause of action the plaintiffs had waived their right of action. He (Mr. Shaw), however, maintained that the defendants were by their own conduct precluded from relying upon the statute, for it was at the written request of their own superintendent architect that the plaintiffs allowed the matter to stand in abeyance till after the next committee meeting, thus delaying the issue of the writ. Counsel then quoted authorities in support of his contention, and argued that the County Court judge was wrong in holding that there had been a waiver by reason of the delay.

Mr. Horace Avory, K.C., denied that the County Council had done anything which precluded them from pleading the Public Authorities Protection Act. Counsel pointed out that all the superintendent architect wrote was that he presumed legal proceedings would not be taken.

Their lordships, in deciding the case, held that the superintendent architect had not actually requested the delay in the issue of the writ, and dismissed the appeal with costs.

CATALOGUES AND PAMPHLETS RECEIVED

ELECTRIC PUNKAHS.—A new pamphlet is to hand from Messrs. Bergtheil & Young in which the "Bandy" patent electrically-driven punkah is described. The method of driving is somewhat peculiar, but is the result of a careful study of the motion which gives the best results. The continuously running motor is suspended with its axis vertical, and by means of a friction drive gives the punkah a sort of "flick" as it swings past, allowing it to swing free at the end of its travel. An arrangement of springs is adopted which ensures that the friction strip passes alternately on each side of the motor pinion, so that with a constant direction of rotation of the motor impulses are given in both directions. A description of the arrangement was given in ELECTRICAL ENGINEERING, Vol. II., p. 611, in connection with the Engineering and Machinery Exhibition at Olympia. Several forms of punkah are made, suitable for ship, shore, and railway use, a number of which are illustrated.

VULCANISED BITUMEN CABLES.—Messrs. Johnson & Phillips have issued a new list dealing with Paterson's vulcanised bitumen cables. A number of illustrations, showing the cables in the process of laying, are included, and full particulars are given of twin and three-core cables up to 0·5 sq. in. conductors in the taped, braided, and single and double armoured varieties. Among the special cables illustrated is a three-core 2,200-volt cable for colliery work, paper insulated, bitumen sheathed, double-wire armoured and served, and a 6,600-volt concentric distribution cable, insulated with vulcanised bitumen, with the outer conductor arranged for bonding to the rail, as made for the London, Brighton & South Coast Railway.

SIMPLEX CONDUITS.—A new price list in the form of a wall sheet with rollers, formed of actual pieces of conduit tube, is to hand from Simplex Conduits, Ltd. We understand that from the beginning of next month the trade discounts for Simplex conduits will be considerably increased. The company also announce that the 1908 edition of their well-known pocket book has been completely exhausted, but that reprints are to be issued in about a week's time, which they will be glad to supply to any of our readers who may not have already received a copy.

STEAM ENGINES AND MACHINERY.—The latest illustrated catalogue from Messrs. E. S. Hindley & Sons is attractively printed in coloured ink, and contains a large number of well-executed illustrations, most of which are new since the last edition. The details and tables of dimensions are also more complete. A number of types of small horizontal and vertical engines are listed for low and high speeds, both separately and as self-contained sets with boilers. Illustrations are given of the firm's suction gas plant and high-speed vertical gas engine, but fuller particulars of these are contained in a separate list. The boiler section includes a large variety of portable and semi-portable patterns. A few pages are devoted to general machinery, including a series of circular and band saw benches.

Electricity in Medicine.—In a summary of the progress in medical applications of electricity, our contemporary, *Medical Electrology and Radiology*, remarks :—In reviewing the events of the year 1907, we can also look back with satisfaction upon the Exeter meeting of the British Medical Association, where electrotherapeutics made its first appearance with a section of its own, and our readers will be glad to see that the electrical section will meet under the presidency of Dr. Reginald Morton in 1908 at Sheffield. We wish the section all prosperity at that meeting. Another item of interest in the past year has been the opening of a new electrical department at St. Bartholomew's Hospital, to carry on the work of the old one founded in 1887. The new department, with its eight rooms, and its simple though complete equipment, should confirm St. Bartholomew's as the *alma mater* of electrotherapeutics in this country. In X-ray work the passing year has seen some progress, mainly in the general improvement of the average level of work. The new Bèclère break has done much to add to the comfort of workers, for it has swept away the uncomfortable and wasteful shunt resistances, the noises and messes of the old jet breaks, and the disagreeables of the Wehnelt. Thanks to the Bèclère break we can now work as comfortably from supply networks of 200 or 250 volts as we can at 100 volts, and also as economically. We note from the same source that there is to be an electrical section at the annual meeting of the British Medical Association at Sheffield, under the presidency of Dr. E. R. Morton.

Electric Light Failure in Paris.—In Paris an accident to two of the dynamos at the Clichy electricity station, on the evening of the 17th inst., caused some inconvenience to the inhabitants and shopkeepers of the 8th and 17th Arrondissements, who were deprived of the light. A good many of the shops immediately closed, and the people in the houses had to resort to candles. Rumours were spread about that another strike had occurred at the electricity works, but this was unfounded, and it was stated that the repairs would be effected in a few hours. The cafés, &c., had to be lighted, however, throughout the whole evening by candle-light.

FULHAM ELECTRICITY WORKS

ONE of the principal points of interest in the works from which electric supply to the Fulham district is obtained lies in the fact that it is one of the most successful existing combinations of a generating station and refuse destructor under municipal control. There are features of interest, too, in the electrical history of the undertaking, but it is not our intention here to enter elaborately in the details of the early days of either side of the concern, but rather to give a few notes on the present conditions under which supply is being carried out.

It may be briefly said that it was in 1897 that a Provisional Order was obtained, although it was not till the beginning of 1901 that the combined destructor and generator station was completed. The original plant, consisting of a group of three 300-kw. two-phase alternators, driven by horizontal Musgrave engines, has come in for some criticism from time to time, but for some years took the whole of the load. These alternators were among the earliest machines built by the General Electric Co. from Oerlikon designs in this country. As will be seen below, the extensions added since form excellent examples of the transition stages from the low-speed to the high-speed reciprocating engine, and thence to the steam turbine. The original destructor plant with its boilers still stands, although certain minor alterations have been made in it to improve its efficiency, but of late years an entirely new coal-fired boiler-house has been added. Another feature of the station is the group of Ferranti rectifiers which are still used for the arc lighting supply. An idea of the general arrangement of the plant can be obtained from the plan in Fig. 1. It will be seen that the engine-room, which is still of its original size, adjoins the destructor-house, and that the new boiler-house has been added on the opposite side. The site is, of course, an advantageous one for condensing water and coal transport, owing to its position alongside the River Thames, but until recently a good deal of inconvenience was experienced through the choking up of the water intakes by sand and river mud. With the perfection of the arrangements for periodically reversing the direction of flow in the pipes, and provision for thoroughly flushing them, this trouble has practically disappeared. A pair of 24-in. pipes are run out into the middle of the river, and a large sump is provided in the quay wall. This can be filled at high tide, and the whole of its contents allowed to pour out through one or other of the river pipes at low tide, so that a powerful flush is obtained. Electrically-driven centrifugal pumps take the water to an overhead tank, from which it passes to the condensing plant. This tank is on the roof of the pump-room, which contains the three original pumps driven by continuous-current motors, and two pumps added later when the new generating plant was installed. One of these is driven by a continuous-current motor, and the other by a two-phase induction motor. Boiler feed water is obtained by a Potter direct-acting steam deep-well pump from an artesian well 500 ft. deep. An electrically-driven pump was formerly used for this purpose. It may be remarked here that, with the exception of this pump and the steam-driven boiler feed pumps, the auxiliary machinery is almost entirely electrically driven. In the case of some of the older plant the continuous-current motors taking current from the exciter bus-bars are retained, but all auxiliary plant put in at all recently is driven by two-phase motors.

A general view of the engine-room, which is 110 ft. by 42 ft., is given in Fig. 2. The plant therein forms a remarkable object-lesson as to the diminution in floor space required by the more modern forms of generating plant. In the foreground are the old 300-kw. Musgrave G.E.C. sets, running at 93 r.p.m., already referred to. Only two out of the original three sets are now standing, as the site of one, or rather part of it, is occupied by the 1,000-kw. Belliss G.E.C. set. This latter set forms the latest plant to be actually erected in the engine-room, although we understand that the order for the turbine set was given afterwards. The alternator, like the old machines, was manufactured by the General Electric Co., and is designed for an output of 167 amperes at 2,900/3,100 volts 50 cycles two-phase, at a speed of 250 r.p.m. The smaller Belliss engine seen behind this set was an earlier addition to the plant, and drives a 600-kw. Dick Kerr alternator running at the same speed.

The most interesting set, however, is that placed in the extreme corner, and occupying by far the smallest floor space. It consists of a vertical shaft Curtis turbine, driving a revolving field alternator of the British Thomson-Houston Co.'s manufacture, with a normal output of 750 kw. at 1,500 r.p.m., and, of course, the same voltage and frequency as the other

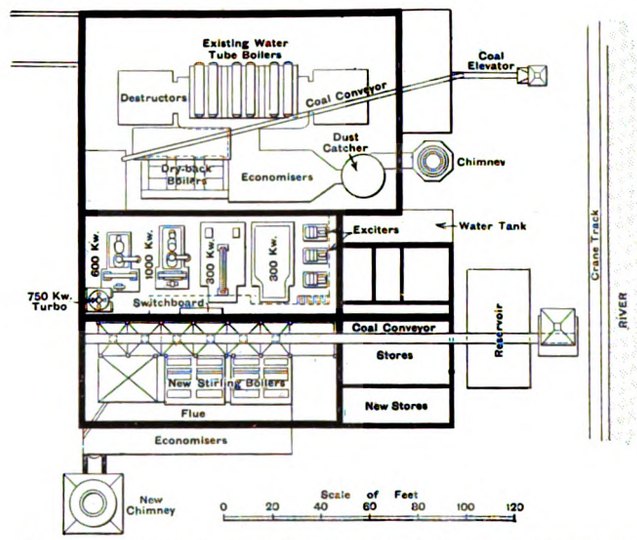

FIG. 1.—GENERAL PLAN OF GENERATING STATION AND DESTRUCTOR WORKS.

sets; the set has a considerable overload capacity, and has given as much as 1,250 kw. for two hours. A separate view of this unit is given in Fig. 3, and it should be pointed out that it was the first Curtis turbine to be actually manufactured in this country. In these days, when so much speculation is rife as to the possibilities of aerial propulsion, it is amusing to read the following inscription upon a licence plate affixed to the machine. "Sold to be used for any purpose except marine or aerial propulsion." The form of the governor-gear is slightly different from that in the more recent Curtis machines, but the general principle of opening and closing a varying number of the 7 or 8 nozzles electromagnetically by means of a commutator actuated by a centrifugal governor is the same. We are not inclined to enter here into comparisons between this and other types of turbine, but with regard to durability there would appear to be much to be said in favour of the very substantial blading employed, which is machined out of the solid, and as to steam consumption the following figures should speak for themselves:—

Steam consumptions of 750 kw. Curtis turbo-generator, as determined at maker's works, and subsequently verified on site, in lbs. per kw. for dry steam:—

Load—	¼.	½.	¾.	Full	50% overload.
Consumption guaranteed with 5 per cent. margin..	25·6	23·4	22·1	21·4	21·8
Consumption obtained from tests	23·35	21·2	19·85	19·35	20·75

Digitized by Google

With superheated steam at 187°F. on a short test at three-quarter load, the result worked out at 16·5 lb. per kw. hour, which, for the size of the set, is very satisfactory.

The pressure-pumps for the footstep bearing are placed in the basement below. These are in duplicate, and each set consists of a small three-throw pump, gear-driven by a continuous-current motor. The condensing plant for this and the Belliss sets is also in the basement, but does not call for any special remark. Three-throw air-pumps of the Edwards & Worthington types are used, all driven by two-phase motors. The condensing plant of the old Musgrave sets was of the ejector type.

None of the sets have direct-coupled exciters, but excitation for all of them is obtained from the three original exciter sets at the end of the engine-room. These consist of four-pole G.E.C. dynamos, each for an output of 600 amperes at 100 to 110 volts, coupled directly to, and driven by, vertical Musgrave engines, running at 460 r.p.m. A historical interest attaches to these sets also, as the engines are among the first of the vertical high-speed type to be constructed by Messrs. Musgrave. It might well be wondered that, with the extensions which have increased the capacity of the station to about three times its original amount, it has not been found necessary to increase the number of these machines, but it should be pointed out that not only were the exciter sets put down of a size sufficient to run a considerable amount of continuous-current auxiliary plant, the place of much of which has been taken by two-phase motors, but also the original 300-kw. sets, which are not now of sufficient size to take the day load singly, are very rarely run. The excitation taken by the new plant, in spite of its greater output, is also considerably less than that required for the original sets. Thus the 300 kw. Oerlikon-G.E.C. machines required 300 amperes each, while the 1,000-kw. set driven by the larger Belliss engine requires 80 amperes, and the 750-kw. turbo-generator only 50 amperes.

The question of further extensions to the generating plant is under consideration, and to make room for this, it is proposed to remove another of the original sets.

Mention was made of the Ferranti rectifiers, by which the arc lighting is carried on; these are now eight in number, and are placed together with the arc lighting switchboard in a separate room adjoining the engine-room. We understand that, on the whole, they work well, but require a good deal of attention.

The main switchboard is on a gallery along one side of the engine-room. The original board was of the familiar Ferranti cellular construction. This is now used almost entirely as a feeder board. The only generator circuit which remains on it is that of one of the slow-speed alternators, which is intended to be removed. To the left of this board is an exciter switchboard, made by the General Electric Co., provided with machine switches and circuit-breakers, and with the exciter bus-bars mounted on the front. The circuits of the continuous-current auxiliaries are taken from this board. The new generating sets and one of the old 300-kw. sets are accommodated on a new board of Westinghouse manufacture on the right-hand side of the Ferranti feeder board. This is provided with oil circuit breakers placed behind the panels, worked by projecting levers, and fitted with time-limit overhead and reverse current releasing relays. The synchronising gear, which includes a Westinghouse rotary synchroscope, is carried on a bracket at the right-hand end of the board. The part of the gallery opposite this board has been fitted with a glass floor.

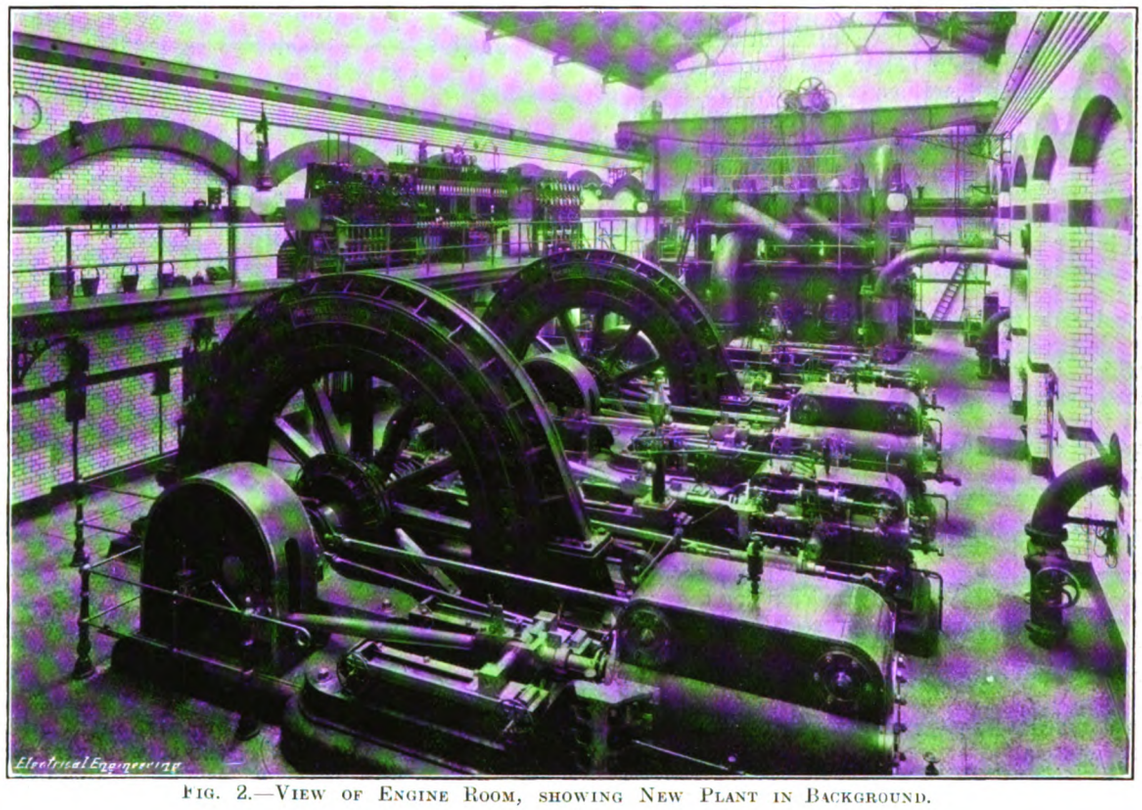

FIG. 2.—VIEW OF ENGINE ROOM, SHOWING NEW PLANT IN BACKGROUND.

Adjoining the engine-room is a small repair shop, equipped with a few machine tools. The equipment of this is to be added to in the near future, and some new lathes and radial drills are to be installed.

The new boiler-house contains a set of four Stirling water-tube boilers, each with an evaporative capacity of 14,000 lb. per hour, and fitted with internal superheaters. It should be remarked that what reaches the engines is really, so to speak, a mixture of superheated and saturated steam, as neither the destructor boilers nor the coal-fired boilers in the old boiler-house are provided with superheaters. Nevertheless, a resultant

Digitized by Google

superheat of almost 100° F. is obtained. Since the construction of the new boiler-house, the original dry back coal-fired boilers in the oil-boiler house are very seldom used, except at times when one or more of the new boilers are laid up for inspection or alteration. When first installed, half the boilers were mechanically stoked, and the remainder hand-fired, but the success of mechanical stokers which are of the "underfeed" type has led to all being similarly equipped. The last boiler is now in process of having the stoking apparatus fitted. The type of stoker being put in varies a little from earlier patterns in the other boilers in having more relative movement between adjacent fire-bars and large air-channels through the bars. Two Green's economisers are installed, and a pair of Andrew & Cameron direct-action, vertical steam feed-pumps are provided. Forced draught is obtained by means of a couple of motor-driven fans. A CO_2 recorder of the "Sarco" type, supplied by Messrs. Sanders, Rehders & Co., is in continuous use in connection with the new boiler plant.

The destructor was constructed by the Horsfall

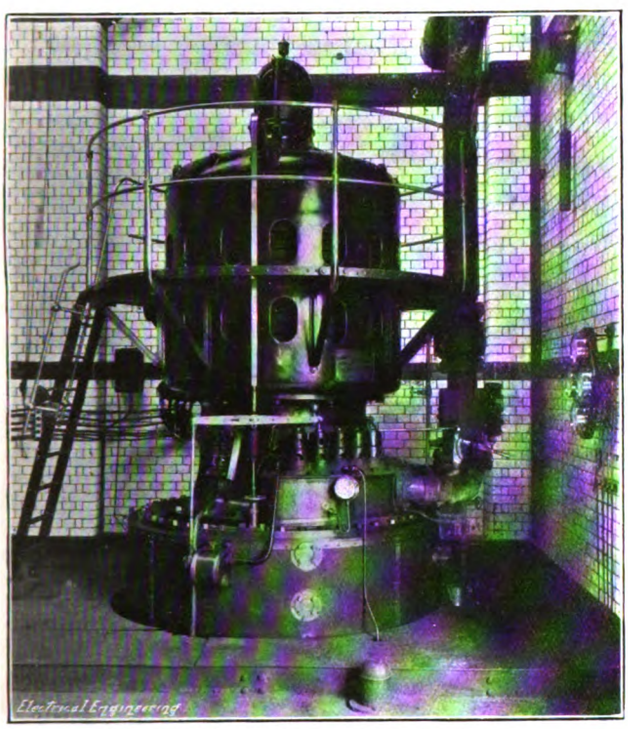

FIG. 3.—750-KW. CURTIS TURBO-GENERATOR.

Destructor Co., and consists of twelve destructor cells of the usual top-feed type, with a grate area of 30 ft. each, arranged six at either end in two rows, back to back, and a row of six Babcock & Wilcox boilers in the centre, heated by the gases from the destructor cells. A Green's economiser is provided in the flue leading to the chimney, and also a circular dust catcher. It is found that the calorific value of the rubbish to be dealt with varies as much as 10 to 15 per cent., but the 12 cells can under all circumstances deal with more than the contract quantity of 120 tons per day.

A very careful watch is being kept over the performance of the destructor, and we understand that very satisfactory results from the point of view of evaporations per ton of refuse are being obtained. The tests are not yet quite complete, so that at present we are unable to publish any figures.

Referring to the plant in its present condition, some alterations in the arrangement of the flues have been made since the plant was first installed, with the object of shortening the passage of the hot gases from the cells to the boilers, and reducing the number of right-angled corners round which they had to flow. The gases now come direct into the boiler furnaces from the side without passing underneath as formerly. Another alteration was the removal of all provision for burning even the smallest quantity of coal under the destructor boilers. The good combustion obtained is shown not only by the high evaporative efficiency but also by the excellent quality of the clinker produced. The treatment of the clinker is a special feature of the undertaking; it is raked from the cells direct into skips suspended from an overhead run-way. Adjoining the destructor-house is a works in which a good quality of clinker brick and paving-slab is made. Although originally under separate control, the department has been, since March 31st last, under the management of Mr. A. J. Fuller, the chief electrical engineer.

Of the steam produced in the destructor boilers, about 50 per cent. is passed into the steam pipes of the electrical generating plant, and the remainder utilised for the auxiliaries of the destructor itself, the clinker and brick making-plant plant and the adjoining municipal disinfector plant. During the earlier years of the undertaking the accounts were so arranged that the amount paid by the electricity department to the destructor department for the steam used was simply the loss on the destructor department's working, which in the year ending March 31st, 1906 (the last financial year during which this arrangement was in operation), amounted to £869, representing 5·8d. per ton of refuse destroyed out of a total destructor cost of 41·1d. per ton destroyed. During the succeeding year, however, a more rational method of charging has been adopted, based on the true value of the refuse. It was at first proposed to charge for steam the equivalent value of 4·5 lb. of coal per unit at the market price of coal during the year, but this figure was afterwards altered to 5·4 lb. per unit, corresponding to an average price of coal at 10s. 6d. per ton. During the first year of the working of this arrangement the figure was £910 or 6·2d. per ton of refuse destroyed. A feed water meter is used to determine the total steam output of the destructor plant.

The following particulars of the working of the destructor during the year ended March 31st, 1907, may be of interest:—

	Tons
Quantity of refuse destroyed	35,222
Largest quantity destroyed in one day	179
Smallest quantity destroyed in one day	48
Average quantity destroyed daily	96
Bye products:—	
Clinker, fine ash, and flue dust	10,340
Tins and scrap iron...	305
Total ...	10,645

The expenditure during the same year is given below:—

	Amount. £.	Per ton of refuse destroyed d.
Oil, waste, water and stores	143	1·9
Electricity for lighting	117	0·8
Wages for workmen	2,406	16·4
Rates, taxes, and insurance	261	1·8
Repairs and maintenance...	197	1·3
Clinker disposal, wages, and stores	(746) (143)	6·1
Management	296	2·0
	4,309	29·4
Interest on loans	663	4·5
Sinking fund	1,424	9·7
Total expenditure ...	6,396	43·6

During the same year the generating works costs of the electricity department averaged 0·8d. per unit, giving with management and other charges 1·123d., and with the inclusion of all capital charges 2·258d. per

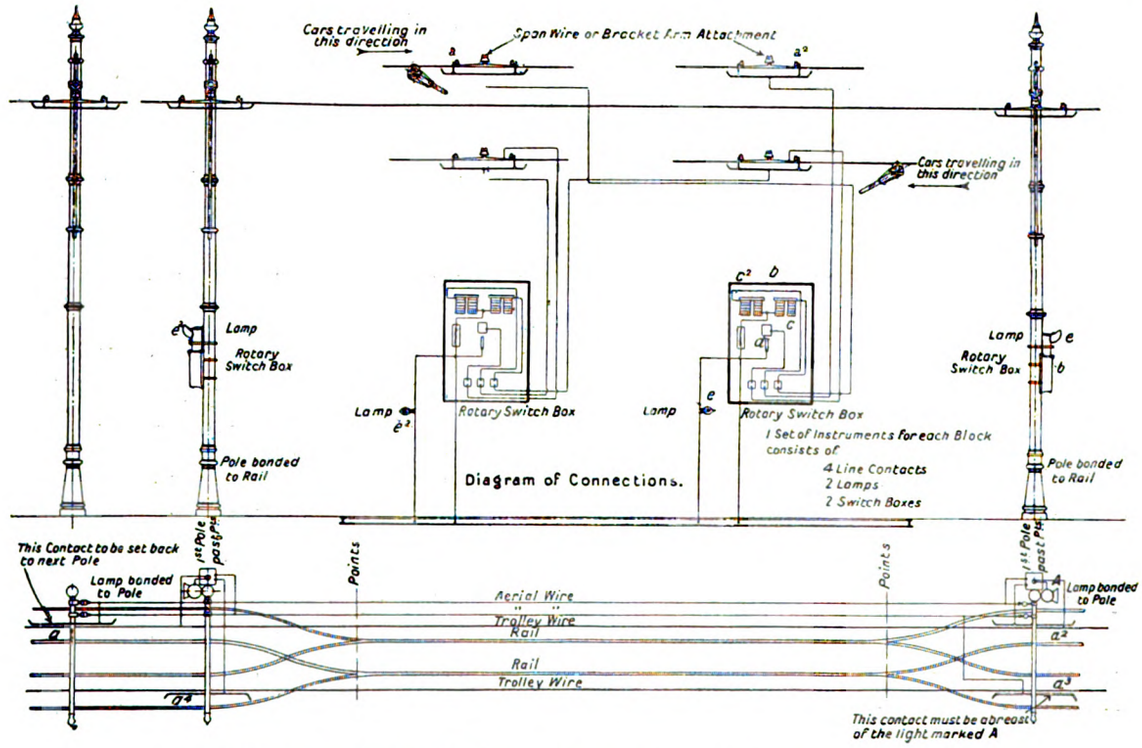
Digitized by Google

unit sold. The total units sold amounted to 2,523,417, and the maximum demand was 1502 kw., with a lamp connection of 110,723. There is a power load at Fulham represented by 1,167 h.p. of motors, and it is interesting to see the proportion in which this is divided among different trades.

Wood working, 247¾; lifts, 80; engineering work, 358½; brick making, 40; stone working, 25; cranes, 96; printing machinery, 5; meat mincing, 31¾; fans, 30; laundry work, 77½; dough mixing, 45½; tobacco cutting, 1; sugar refining, 30; chaff cutting, 15; boot burnishing, 16¾; hair brushing, 1½; coffee roasting, 2; electro plating, 1; private, 3¾; bookbinding, 30½; chocolate making, 9½; potato cutter, 1; polishing paste, 2; lamp making, 3½; bottle washing, 12½.

Fulham was, we believe, the first London district where the price of 1d. per unit for power was introduced, and now the average price received per unit is, with one exception, the lowest in London.

In conclusion, we should express our thanks to Mr. A. J. Fuller, borough consulting and electrical engineer, under whose specifications the extensions referred to have been carried out, for the facilities for the preparation of this article.



AUTOMATIC SIGNAL FOR TRAMWAYS

Burton and Ashby Light Railway

A METHOD of automatic signalling which has been applied on the Burton and Ashby Light Railway, belonging to the Midland Railway Company, is described in the *Railway Times*. The method allows for cars to follow each other through a section, but no opposing car may enter until all those from the opposite direction have arrived and passed off the single line section. For each section there are employed four overhead line contacts, two sets of lamps, and two switchboxes. Each road has an ingoing and an outgoing contact, which is attached to the trolley wire. The trolley wire is not broken, but goes straight through, and when the trolley head passes the contact the latter is pushed aside so that an electrical circuit between the trolley wire and the contact is closed. The general arrangement is indicated in the accompanying figure.

A car travelling from left to right first makes contact with a, which causes current to flow from the car into the rotary switch-box b, causing magnet c to be energised, so that the rotary switch d revolves one step forward and thereby switches in the light e. Should a second car enter the section before the first had left, the rotary switch is moved another step forward. When the first car leaves the section it makes contact with a_2, so that the magnet c_2 is energised, and this revolves the rotary switch d one step backwards. Were it the only car, the switch would have only moved one step, so that this backward movement would have put out the light e. If, however, there is a car still in the section, the light would remain burning until the rotary switch had been stepped back to normal. For a car entering from the other end, contact would be made at a_3, and broken at a_1, and the light e_2 would govern the movements One of the pair of ingoing contacts has to be 40 yards length back from the lamp, so that it may light the lamp at the other end before a car can enter from the opposing end, also that of two cars entering simultaneously one shall have a greater advantage of securing the road.

The lanterns may have a single light or may be provided with two or three lights, where it is considered necessary to advise a driver as to how many opposing cars are in the section. The lamps are shaded by a hood. The ingoing contacts are staggered, so that there is no possibility, in the event of two cars passing under them simultaneously, of their both entering the block section, as the driver coming from the end at which the contact is farthest from the points would see the danger light before he got to them.

ARRANGEMENT OF AUTOMATIC SIGNALLING ON BURTON AND ASHBY LIGHT RAILWAY.

Construction of Highgate Tramways.—In the King's Bench Division of the High Court on Friday, Mr. Justice Channell had before him the case of W. Griffiths & Co., against the Middlesex County Council. Mr. Salter, for the plaintiffs, said there was a contract between parties for the construction of an electric tramway, starting from Highgate and running north. The contract provided that the contractors were to commence the work when instructed by the defendants, and they were bound to finish in six months. When plaintiffs did commence the work it was found that all the usual arrangements and adjustments had not been made, and, in consequence, a series of delays began, with the result that instead of starting on February 11th, 1903, the plaintiffs were obliged to wait until August. Consequently the entire work was thus disorganised and altered, and instead of it being a summer job, it was turned into a summer and winter job, causing a loss to the contractors, the plaintiffs, of something like £10,000. Plaintiffs brought their action, alleging, in substance, that there was in a contract of that kind a duty on the part of the employers, the defendants, of co-operation to facilitate the work in reason. That was the duty plaintiffs alleged defendants had not carried out, and they had sustained damage in consequence. The defendants alleged that there was no such implied term in the contract. The case was continued on Saturday, and, after hearing arguments, his lordship reserved judgment.

THE ELECTRICAL EQUIPMENT OF A MODERN ENGINEERING WORKS

A FINE example of a modern engineering works, throughout the whole of which electric motive power is employed, is to be found at the Dartford iron-works of Messrs. J. E. Hall & Co. These works, which were formerly driven by steam and gas power, transmitted by means of shafting and belting, in the various departments, were converted to electrical driving in 1901. The change over was carried out entirely by Messrs. Hall & Co.'s own electrical staff, and was accomplished without interfering in any way with the works. No inconvenience or delay was caused, and no portion of the works had to be shut down for this purpose. Motors were installed in all the departments, the power required having been previously carefully calculated, and each department was at the same time furnished with two distribution boards, one for power, and one for lighting, the lighting circuits being in all cases entirely separated from the power supply. Since the conversion took place, many additions and extensions have been effected, and ample provision for the application of the electric power has been afforded in all the different departments.

The plant in the power-house is excellently adapted for the driving of these works. In the boiler-room are two, 28 ft. by 7 ft. Lancashire boilers, with twin furnaces, which are hand-fired. Each boiler is provided with dead-weight safety-valves, and high and low water alarms, and the usual fittings. The superheaters are of the Bolton vertical tubular form, by Easton & Co., and these are placed in the flues at the end of the boilers. The feed water supply is passed through a caustic soda softener plant before entering the boilers, and the condensed water is passed through a Harris-Anderson oil-separator plant. The water is then passed through a Carter economiser, and thence into the boilers.

The plant in the engine-room consists of two three-cylinder compound high-speed sets (Fig. 1) by Messrs. Willans & Robinson, each for 350 b.h.p., running at 350 r.p.m. These are direct-coupled to two of the Electrical Construction Co.'s compound-wound generators, each rated at 220 kw., giving an output of 1,800 amperes at 120 volts. The engines work at a steam-pressure of 150 lb. per square inch, with superheated steam to 500° F., and have a steam consumption with saturated steam of 21 lb. per kw., and with superheated steam of 17 lb. per kw. The combined efficiency of these sets at full load is about 87 per cent., and the sets are capable of dealing with an overload of 25 per cent. for one hour. The exhaust steam from these engines is passed through a surface condenser, into which the exhaust steam from the auxiliary plant is also taken. There is also a 60-kw. direct-coupled motor-generator set by the E.C. Co. (Fig. 2), which obtains its motive power from the Dartford Council's supply station. The supply side is taken directly off the traction feeders of that supply at 550 volts, and the motor is shunt-wound, with auxiliary commutating poles, and works without sparking on variable voltages and fluctuations of load. This set is used when the works plant is shut down, principally through the night. The generator is compound-wound, with auxiliary poles, is arranged for 120 volts, and is capable of sustaining sudden over-loads without sparking or overheating. The set runs at 600 r.p.m. This set can also be employed to supply power to the Council mains when required, the only alterations necessary being the cutting out of the compound winding on

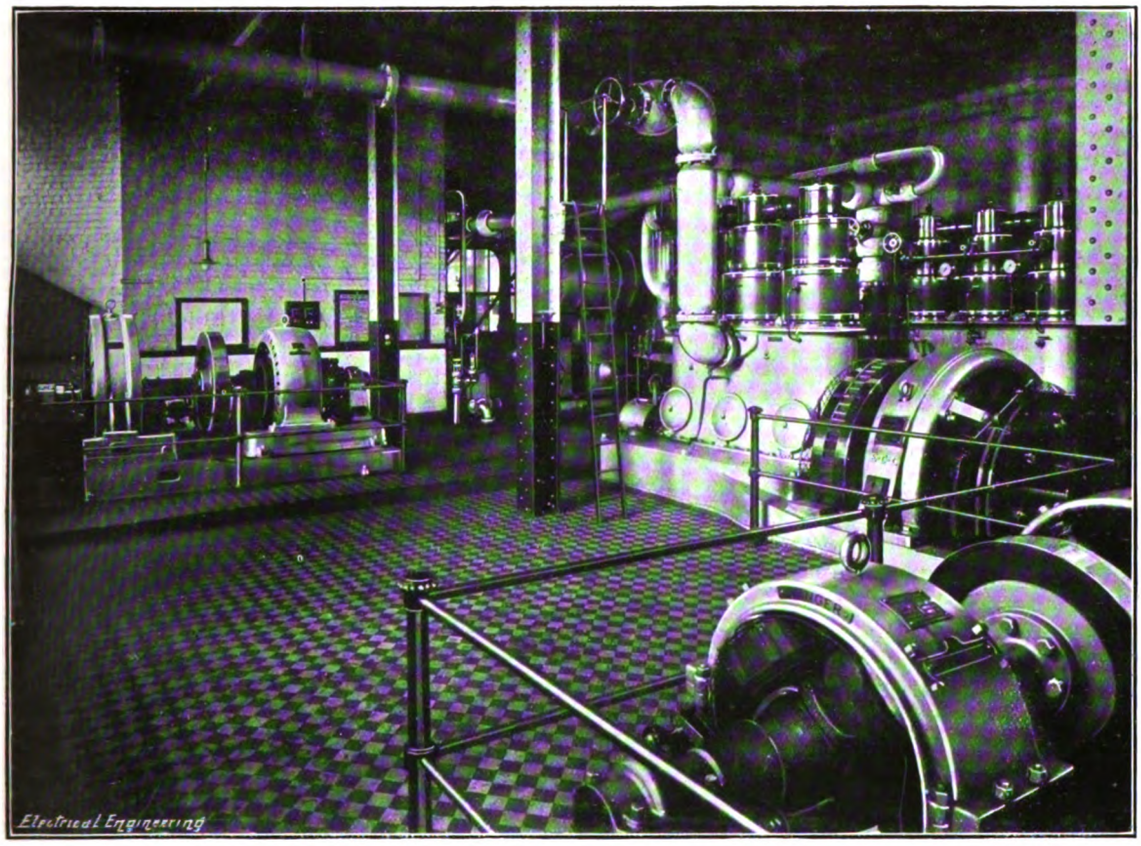

FIG. 1.—ENGINE ROOM, SHOWING GENERATING SETS.

Digitized by Google

the generator side, for which due provision has been made.

A 21-kw. motor-generator set similar to the above in construction is also provided. The motor side was manufactured by the E.C. Co., and the generator by the Brush Engineering Co.; this machine was assembled and the combination effected by the works electrical engineer, and is used for light loads, so as to economise on the larger sets.

As a great amount of current is required in the works for the electric welders, an extensive plant has been installed for that purpose, and consists of a 52-kw. direct to alternating-current motor-generator (see Fig. 2), running at 750 r.p.m. The direct-current side consists of an 80-b.h.p., shunt-wound, six-pole motor, by the International Electric Co., and is coupled direct to a 52-k.v.a. (E.C. Co.'s) single-phase alternator, with an output of 150 amperes at 350 volts at 50 periods. The combined full-load efficiency of the sets is about 84 per cent. These units were also assembled on the premises, having been formerly separate units. A heavy fly-wheel is interposed between the two machines on the armature shafts, as the set has to deal with very sudden loads. This fly-wheel has the effect of ensuring excellent regulation. There are also two direct-current to alternating-current motor-generator sets, each of 35-kw. capacity, running at 1,500 r.p.m., the direct-current motors being 50 h.p. shunt-wound by Scott and Mountain, coupled to 35-k.v.a. single-phase alternators by the British Thomson-Houston Co. These sets are each used in turn with the aforementioned 52-kw. set, and are arranged to run in parallel, and, when this is done, very large welding operations can be carried out. The efficiency of these sets is 80 per cent. on full load.

The main switchboard, which is shown in Fig. 3, is situated on a gallery about eight feet above the engine-room floor, and overlooks the whole of the running plant, so that the attendant has complete surveillance over the generators. It is mounted on channel and angle iron frame work, and is practically fireproof, as no inflammable material enters into its construction. The conductors from the generators, and also to the power and lighting circuits, are of bare copper rods, mounted and secured in porcelain insulators, bolted to channel and angle iron supports. All the positive conductors are enamelled red, and the negative black. The alternating circuits are distinguished by blue and white enamel, so that any conductor can be identified without difficulty. All positive feeders are run overhead, and the negatives behind the board, so that the chance of short circuits occurring is very remote. The various field regulating and starting resistances have been manufactured on the premises and are fireproof, mounted beneath the steel plates which form the floor of the gallery. No soldered joints enter into their construction. They are operated by pedestal hand-wheels on the gallery, and are connected by means of chain-gear and sprocket-wheels. The controllers for the high-voltage motor-generators are connected by worm-gear, and fitted with an interlocking switch-gear, which makes it impossible to close the main d.p. switches, unless the starting rheostats are in the "off" position. All motor and generator circuits are provided with d.p. cut-outs and circuit-breakers, on their positive poles, and their negative pole is "earthed," to enable the various cranes to have the advantage of an earth return; this also provides for a three-ton Jessop & Appleby locomotive crane, which runs through the various yards. The synchronising gear consists of a rotary indicator and two step-down transformers for paralleling the welding alternators, all arranged so that it is almost impossible for a mistake to be made, and if the rotary synchroniser should fail, a synchronising lamp is available. The motor fields are controlled from variable resistances, wound and stepped to suit the peculiar field characteristics of each machine, to enable fine adjustments to be made, the exchange between the machines being very small on all loads. The switchboard consists of sixteen panels of slate, each being 6 ft. by 2 ft., mounted on channel steel frames, securely bolted to the gallery, and special girders built into the walls for this purpose. The total length of the board is 33 ft., with ample space both at the front and back, giving ready access to all cables, switches, and instruments. The panels are disposed as follows:—Nos. 1 and 2 are for lighting feeders only, and are provided with two moving coil ampere-meters for the output, and also a total output ampere-meter, a d.p. emergency main fuse, and switch fitted with duplex fuses, so that no delay occurs in replacing fuses, it being only necessary to throw over the switch should one blow.

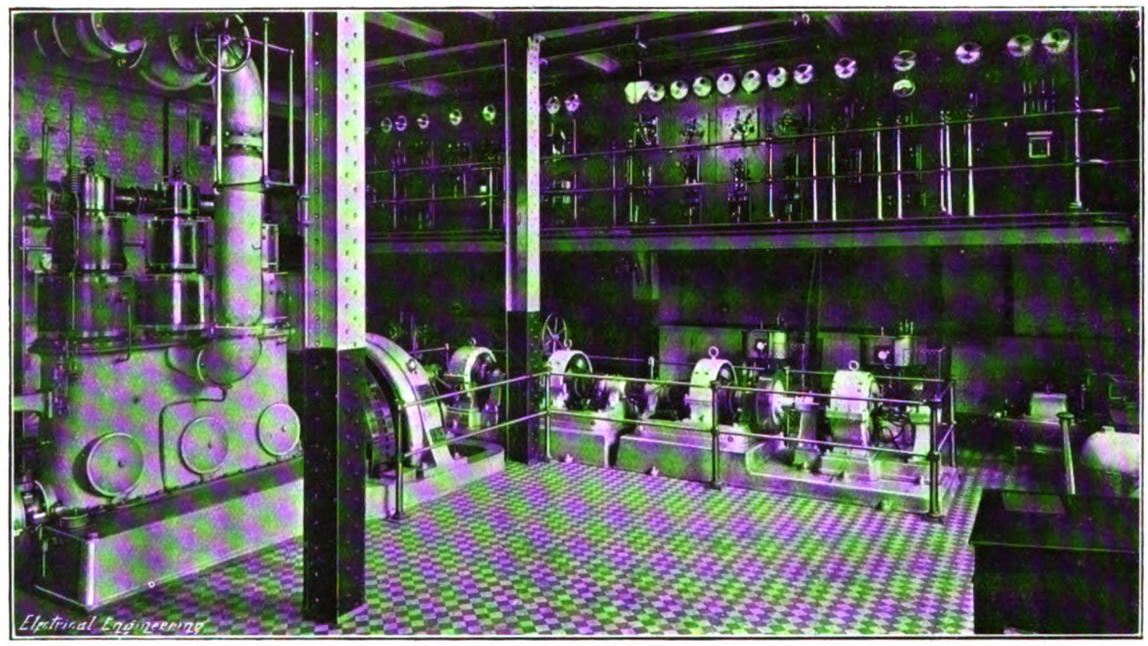

FIG. 2.—ENGINE ROOM, SWITCHBOARD, AND MOTOR GENERATORS.

Digitized by Google

Nos. 3, 4, and 5 panels are power panels, supplying the feeders to all the different departments, and are fitted with d.p. quick-break switches, cut-outs, and ammeters, similar to those on the lighting panels. They have integrating and recording wattmeters for measuring the total output of the station. From these panels current is also supplied for the testing of the engines in the automobile shops, and a meter is provided on which debit and credit readings can be taken, as the generator in the automobile department is arranged to run as a shunt-motor when required. Nos. 6 and 7 panels are 220-volt generator panels, and are equipped with 9-in. ampere and voltmeters, and auto-reverse cut-outs with polarised coils, making reversals beyond 10 per cent. impossible, a d.p. main switch, two single-pole 2,000-ampere cut-outs, and a single-pole equalising switch, an equalising bus-bar being provided, to which all the generators are connected. Field regulating pedestals are placed in front of each panel. No. 8 panel is a spare, and No. 9 panel is for the low-tension side from the Dartford supply, and is provided similarly to Nos. 6 and 7 panels, and has in addition a horizontal edgewise double-scale voltmeter for paralleling purposes. Panels 11 and 12 are arranged for starting the 120-volt motor sides of the 52 and 35 kw. electric welding sets, each panel being provided with a moving coil amperemeter, voltmeter, starting-controllers with renewable contacts, double-pole main switches and cut-outs, and maximum load cut-outs on the positive poles, and each panel also has a motor and generator field controller for the parallel running. Panels 13, 14, and 15 are all alternator panels for electric welding work, and each is equipped with maximum alternating circuit-breaker, soft-iron ammeter, a three-way voltmeter, synchronising, and double-pole switches, double-pole field-switches, main, and feeder switches, and a double-scale hot-wire voltmeter for observing the voltage of the incoming machine. No. 16 panel contains the starting-controllers for the 550-volt side from the Dartford supply for both motor-generators, and has double-pole main switches, with interlocking gear, s.p. cut-outs, and worm-gear starters. A Thompson wattmeter is arranged to check the readings of the supply meter. This board has been fitted up by the electrical staff for the particular requirements of the works. The motors employed in the works are all of the direct-current type, and vary in size from ½ h.p. to 25 h.p. The various departments are arranged into the sections most suitable for the purposes for which they are employed. Raw hide pinions are largely used for the gearing of the motors. In the automobile engine manufacturing shops the motors are disposed overhead, thus economising space, and each motor drives a section of the shafting driving the lathes, except in the case of some of the heavier tools, when the motor is geared direct on to the machine. The switchboards for controlling these motors, and also for the lighting of the works, are built on iron galleries some 12 ft. above the floor, thus economising the space. The total number of motors installed throughout the works is 130, and these in many cases work on full-load throughout the whole day. Foolproof starting-switches are provided, to prevent accidents. All the travelling-cranes are electrically equipped, and a three-motor 10-ton crane installed some four years ago has, it is claimed, greatly increased the output, owing to its rapid and flexible manipulation. The testing of the completed petrol engines is conducted without waste of power, as the generator employed is placed in parallel with the mains, and its power is used to assist the general power plant. The electric welding is carried out on the "Thompson" welder, the primary voltage being 350, stepped down to about 4 volts. The controlling of the current is

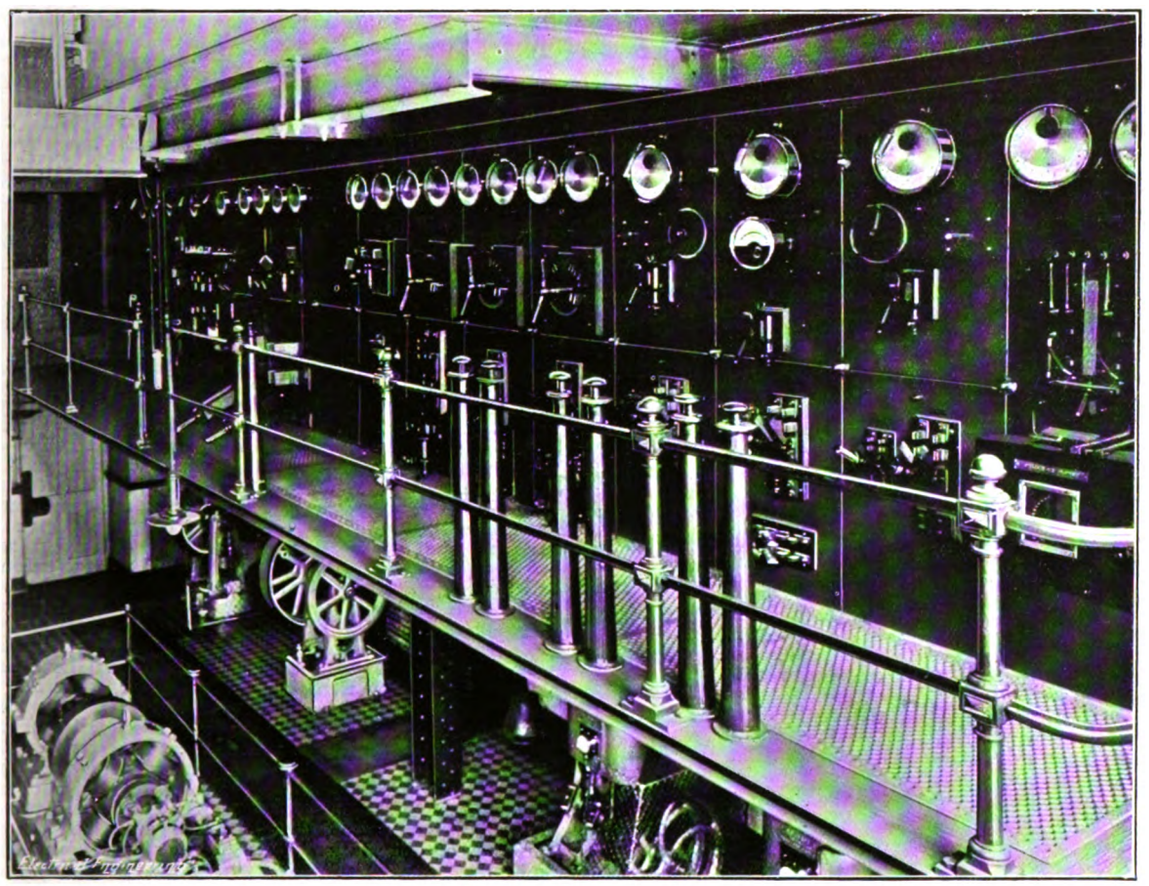

FIG. 3.—SWITCHBOARD.

Digitized by Google

carried out by auto-transformers placed in the primary circuit, and controlled by worm-gear. The welding-machines are designed for carrying heavy currents, and are water-cooled throughout. The current used is single-phase alternating as mentioned previously, and is conveyed from the switchboard on 19/16 cables, which pass through an automatic switch, and render it impossible to switch on the current unless the controller is in the off position. The power required to make sound welds on iron and steel piping, &c., varies a good deal, but the average is about 35 k.v.a. per weld. All the machines, controllers, &c., are carefully earthed to ensure the safety of the operators. We are indebted to Messrs. J. & E. Hall & Co., and also to their electrical engineer, Mr. B. Smith, for the facilities and information given us for the compilation of this article.

BRITISH ENGINEERING TRADE WITH CANADA

IN September, 1906, Mr. Richard Grigg, a Special Commissioner of the Advisory Committee to the Board of Trade on Commercial Intelligence, commenced the task of an exhaustive investigation into our trade with Canada. His work was completed in May, 1907, and he has now presented a report upon the conditions and prospects of British trade in the Dominion. The document contains some passages specifically relating to the electrical industry, but inasmuch as his conclusions and advice are not intended to apply to any one particular industry, we give a general *resumé* of what he has to say.

Among all classes in Canada, he says, there undoubtedly exists a strong desire to buy goods from British sources whenever possible, and this desire is reflected in the tariff preference on British goods. The fact that his Majesty's Board of Trade had instituted an inquiry, and had decided to appoint correspondents to furnish regular information to its Commercial Intelligence Branch, has been received with marked approval as indicating a desire on the part of the Home Government to promote closer commercial relations with Canada. In a general review of the natural and industrial conditions prevailing, the report contains the following under the heading "Electric Power":—

"The development of electric energy from water-power and its transmission is a matter of the utmost importance in Canada, both because coal for steam-raising is dear (about $4 per ton in Ontario), and because of the very numerous waterfalls which are available for the production of power. Chief among these is Niagara Falls, where works now approaching completion on the Canadian side will have an ultimate capacity of 400,000 h.p. On the American side about 300,000 h.p. is being generated and successfully used, largely at Buffalo, a manufacturing city distant about 25 miles; but transmission wires (60,000 volts) have been carried 163 miles to Syracuse, and current is being delivered there. In Canada current is being delivered from Niagara to Toronto (81 miles distant) for both power and light, and it is proposed to run transmission lines from Niagara to London (Ont.), a distance of 119 miles, supplying a number of towns on the route.

"The manufacturing city of Hamilton is using about 20,000 h.p., generated 35 miles away, carried at 40,000 volts, and reduced to 2,500 volts, with a somewhat complicated scale of charges, but said to work out at $22.50 per annum h.p. in the case of a factory using 150 h.p. 10 hours per day for 300 days. The official report of the Ontario Power Commission (appointed by the Ontario Government) estimates the actual cost of production at Niagara at $4.95 per h.p. on the basis of a production of 100,000 h.p., and the cost of delivery to the municipal switchboard at Brantford, 69 miles away, at $11.37 per h.p. Immense reserves of water power exist at other points in Ontario (estimated at 1,000,000 h.p. within 50 miles of Ottawa), in Quebec, and, indeed, in all the provinces. It will be seen that such conditions have an important bearing on the problem of future industrial production. The Census of Production shows the amount of capital invested under the heading of electric light and power as $11,891,025 in 1900 and $80,393,445 in 1905. A large proportion of the increase is represented by the expenditure on the three electric light plants referred to at Niagara Falls, but the value of the production under this heading is shown as $2,038,017 in 1900 and $7,587,899 in 1905, and it should be remembered that neither of the Niagara Falls works had begun to supply power in the latter year."

The general characteristics of the Canadian market are that, as a whole, it reproduces to a very large extent the main features presented by the United States, both in regard to its industries and the habits and life of the people. At the same time, it is pointed out, there is not the slightest doubt that the desire of the Canadian people is towards trade with the United Kingdom, both for reasons of sentiment and also because of a belief in a real community of commercial and trade interests. The present preferential treatment of British goods varies from 2½ per cent. to 15 per cent. *ad valorem*, the rebate on many of the articles being 10 per cent. *ad valorem*. This tariff came permanently into force in March, 1907, in place of the previous general preference of 33⅓ per cent. So far, the electrical industry has not made any serious inroad into the trade to be obtained in Canada. Taking the import figures for 1906, it is seen that in the supply of electrical apparatus the United States was unchallenged. They imported to the value of $5,461,000, whilst only $81,500 is shown under this heading from Great Britain, although, no doubt, some electrical machinery has found its way into the country under the heading of "Machines and Machinery," in which again, however, American supremacy is especially marked. The geographical position of the United States is largely responsible for the circumstance that in the engineering industry in general, and the electrical engineering industry in particular, British trade has either been entirely defeated or retains only a small and relatively insignificant share of the market. But in the view of Mr. Grigg, having regard to the natural preference for British goods even at higher prices, British manufacturers can do much to counterbalance this disadvantage, such, for instance, as the maintenance of larger stocks of their goods in Canada, and a better appreciation of the conditions to be met there than appears to be the case generally at present. The report condemns the British custom of depending upon merchants and agents to get at the consumer, and also the absence of specialisation for the market. In but very rare cases, it is pointed out, does the British manufacturer adapt his goods to Canadian requirements, the very antithesis of the methods adopted by American and even German importers. In many smaller details, the report gives the impression that British firms have treated the Canadian market with a certain amount of indifference. Methods of packing need improvement, prices should be quoted c.i.f. and not f.o.b., and better terms of credit should be granted. Finally, there is the very important matter of currency and weights and measures. Over and over again it was impressed upon Mr. Grigg that British traders should adopt Canadian weights and measures, and quote in dollars and cents.

In his conclusions, the Commissioner admits that the geographical position of the United States makes it inevitable that a proportion of Canadian trade should fall to that country. Further, he points out that the Canadian home manufacturer is now becoming a serious competitor alike with the United Kingdom and the United States. Consequently, between Canada on the one hand and the United States on the other, it is self-evident that only the most strenuous and persistent efforts can maintain, to say nothing of extend, British trade with the Dominion. It is suggested that British manufacturers should consider the placing of branch factories there, a course which would not only gratify Canadians, but would give manufacturers a more intimate acquaintance with the market, and enable them to maintain stocks more easily. This suggestion is made to counteract the advantage which American firms have obtained by importing partly finished materials from home works and completing the work upon them in Canada. Quite apart from this method of procedure, however, Mr. Grigg is confident that there are many ways in which British traders should be able to strengthen their hold, and even increase it, upon the Canadian market. Efforts should be made to promote and encourage facilities of quick and cheap transportation and communication, and he quotes instances in which orders have gone to the United States for this reason alone. A cheapening of telegraphic communication is also desirable. He reiterates the opinion that the home producer should enter into direct communication with the Canadian buyer, and that attention must be turned to the problem of distribution under the new trade conditions which prevail to-day. Goods are now produced for the Canadian market which are *too good*, and, laudable as a high standard of workmanship may be, it does not always necessarily mean that the commodities sell. A point of importance in this connection is the question of standards, particularly in regard to iron and steel. Canada has adopted American standards, engineers and architects are familiar with them, and if British manufacturers wish to sell in the Canadian market, they must adopt, for goods destined for that market, the same standards also. Greater and more careful advertising is recommended, as well as a more complete and effectual system of distribution of trade literature, matters upon which it is recommended that Canadian advice be taken. National trade representation is the subject of the final conclusion of the report. At present Great Britain is totally without any such representation. The appointment of commercial correspondents such as is now contemplated by the Board of Trade is welcomed as an important step in the right direction, and likely to be ultimately of substantial advantage.

A New French Electrical Journal.—For some time the official organ of the "Syndicat Professionel des Usines d'Electricite" of Paris has been the *Bulletin des Usines Electriques*. It is now announced that from henceforth the place of this will be taken by a new publication, entitled *La Revue Electrique*. The new journal will be published twice a month, and will have forty pages of reading matter instead of the sixteen contained in the *Bulletin*.

COST OF ELECTRICAL POWER FOR INDUSTRIAL PURPOSES

THE discussion on Mr. John F. C. Snell's Paper on the "Cost of Electrical Power for Industrial Purposes," before the Institution of Electrical Engineers, was concluded on Thursday. We gave an abstract of the Paper, and of the discussion in London and Dublin on January 9th, in our issue of January 16th.

Mr. C. P. SPARKS (Engineer-in-Chief, County of London Electric Supply Co., Ltd), referring first to Tables I. and II. of the Paper, dealing with the cost of independent supply, said that Mr. Snell put a new position before them. For some years past it had been almost recognised as an axiom that the most economical thing for everybody to do was to take power supply from some huge bulk station, but the figures Mr. Snell now brought forward, until they had been carefully examined and considered, appeared to show in the first instance, that small independent plants could produce electricity at very much lower rates than it was possible for a large bulk undertaking to do. Table XIV., column 2A, gave some suggested prices for the supply of alternating current to power consumers, and column 4 of the same table gave Mr. Snell's estimate of the prices at which the Newcastle Electric Supply Co. could supply, and on comparing these with Tables I. and II. it appeared that the company could only supply consumers up to 100 h.p. more cheaply when their load factor was above 30 per cent., and that they could not expect to supply consumers between 100 and 500 h.p., no matter

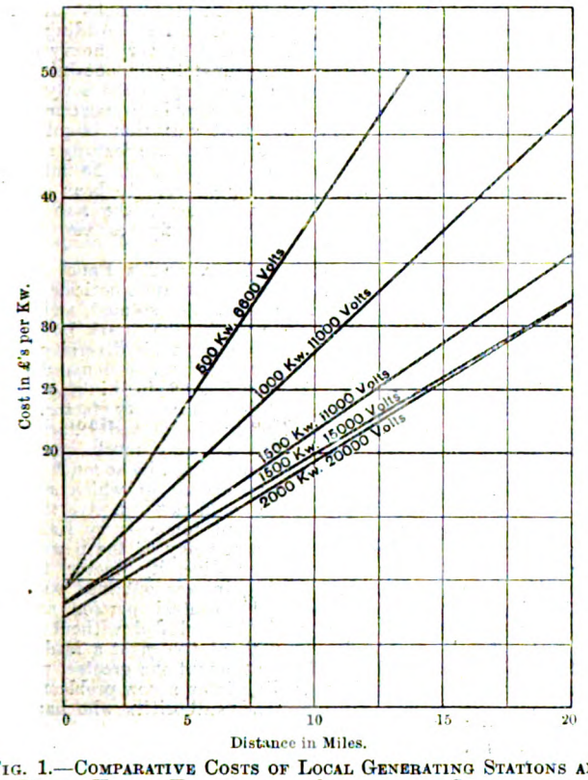

FIG. 1.—COMPARATIVE COSTS OF LOCAL GENERATING STATIONS AND POWER HOUSE, TRANSMISSION SYSTEM WITH SUB-STATIONS.

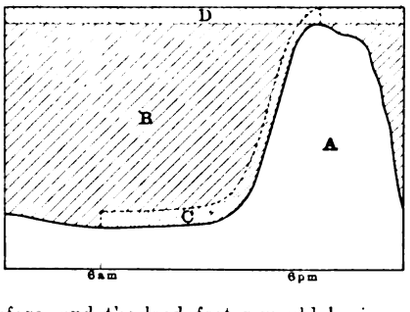
what their load factor. He thought that Mr. Snell's Tables I. and II. were inaccurate in this respect; they represented the kind of costs that were obtained when the independent plant was new and in perfect order, but the working costs given were too low for the average case. So far as the average user was concerned, the figures must be put on a much higher level. The second point he wanted to take was in connection with mill work. He agreed with Mr. Snell in his estimate of gearing losses in jute mills. In modern well-arranged mills, driven by steam engines, the figure of 30 per cent. given by the author was, if anything, on the high side. His own experience showed that it ranged from 25 per cent. to 30 per cent. The advantage of electrifying a mill with a gearing efficiency of this kind was small, for, as a general rule, it was not possible to put the motor on the actual textile machines to be driven. There were, however, other reasons for electrification, namely, the advantage of a smoother method of driving, and the fact that the power was delivered right up to the machines; which resulted in there being no slip. It was for these reasons that mill driving was growing, and would grow, without any regard to the cost of power. Mr. Snell had suggested that the price of electric energy should be about 0·48d. per unit. From his experience he thought that this figure was something near it as a kind of practical result that could be obtained from independently driven small mills. With regard to collieries and larger power users, Mr. Snell had extracted some details from the Paper which he (Mr. Sparks) read before the Institution of Electrical Engineers a short while ago, which showed how difficult it was for a power company to supply a really large power user, and it was on this point that he would like to refer to Fig. 1 in Mr. Snell's Paper, which dealt with the question of capital cost per kilowatt. At the side of the curve was the figure £20. Whilst £20 might be a fair figure for some undertakings, in the case of concerns having from 1,500 to 3,000 kilowatts of plant installed, the cost was from £11 to £13 per kilowatt. The consequence was that there was hardly any chance for a power company to supply under these conditions except at a very limited radius. In the case of a colliery, the question of coal, which was assumed for the curve to cost 11s. per ton, was again a difficulty in the way of a power company, and it showed that for a large colliery undertaking it was almost impossible for a power company to supply. With regard to Table III., he was surprised on reading this to find the very small number of units put down per horse-power. Mr. Snell had taken as his basis the units per head. This he thought was altogether erroneous. The basis of units per horse power was in every way preferable. In front of Table III. the author said, "In Sunderland at the time of the last census, for which the author was responsible, and omitting the large engine works and shipyards, there were 587 motors, representing a total horsepower of 1,634, or an equivalent to 1,220 kw. The maximum demand on the station plant was only about 500 kw. There was thus a diversity factor of 2·4, the total units for the year being 404,999 or 332 per kilowatt installed. This represented a consumption of 810 units per kilowatt demanded for this particular load, and was thus under an average load factor of 10 per cent." This was only 250 units per horse-power, and he thought there must be some reason for this. Possibly they were not all connected the whole of the year, but from figures from various parts of the country, he was sure that 250 units per horse-power was an exceptionally low figure. Before closing his remarks he would like to say a word with regard to the lighting business. Mr. Snell had said: "But a warning should be noted by station engineers that the future will bring, in all probability, a very large proportionate increase of low price power units, and with improvements in lamps and their reduced energy consumption, the proportionate lighting units may even fall below their present figure." He disagreed with this entirely. The use of metallic filament lamps, while causing a falling off of the actual demand of the lighting consumer, did not diminish the number of units consumed, which was the important factor.

Mr. ROBERT HAMMOND thought that the Paper would be remembered as the one that brought prominently before the Institution the very great effect of the diversity factor upon the cost of electrical energy when supplied from central stations. Electrical engineers agreed that the diversity factor had as much effect upon the station load factor as long hour use, since the station load factor was the product of the average consumer's load factor and the diversity factor. If, for instance, £7 per kilowatt of the station maximum demand was found to be the sum required to cover all the standing charges, then it was obvious that with a diversity factor of 1·66, the charge to the consumer to cover the standing charges would be reduced to £4 4s. per kilowatt on about a 20 per cent. load factor. That figure gave an allowance to the consumer of about 0·35d. per unit. This was the figure of which the consumer got the advantage by taking his supply from a central station. It must, however, be borne in mind in speaking of 0·35d., or any other figure with which the consumer might be credited, that to give each consumer the same allowance would be obviously unsound, because the consumer, for instance, whose maximum load coincided with the top of the peak did not help the diversity factor, but he injured it. Instead of having an allowance, he should absolutely be charged more than the figure which represented the standing charges of the station. However, the time would possibly come when a scientific scale would be thought out by means of which each consumer would receive that allowance which his effect upon the diversity factor warranted. From the marked effect that the diversity factor had upon the costs, one would suppose that it would be best for all consumers to obtain their supplies from big stations, especially when, in addition to the advantage of less capital expenditure upon big stations, there was the additional advantage that the plant was more efficient, and there were also savings in wages and in maintenance. In London there was also the advantage of being able to choose the site on the river, where there was ample water for condensing, and where steamers with sea-borne coal could come alongside. One was therefore somewhat staggered at the very low costs that were quoted in Mr. Snell's Paper as those obtainable by power users having their own plant. He was rather afraid that Mr. Snell, with his usual desire to be extremely fair to the other side, had looked on these figures far too leniently. In Table II., which dealt with loads from 100 h.p. to 500 h.p., the price which Mr. Snell set out as



Digitized by Google

the figure for a load factor of 25 per cent. 0·59d. per unit, but 0·95 appeared further on in the Paper as the actual cost to a particular consumer with a maximum load of 504 kw. Again, on a 35 per cent. load factor, the costs set out in Table II. were 0·494d., while at Vickers, Sons & Maxim's works Mr. Williamson, with a load factor of 37 per cent., had a cost of 0·716d. Again, in Tables VIII. and IX., Mr. Snell dealt with the actual cost of the big power undertakings in this country, which were supplying very large quantities ranging from 3,000 to 25,000 kw., which latter was now the power supply in Manchester, as well as in Glasgow. One would expect to find a very great improvement on the 0·59d. in regard to these undertakings. But in the case of Leeds the cost was set down at 1·37d. If a private consumer with a 200 kw. plant could produce at 0·59d. with a load factor of 25 per cent., could it be said that the mere moving of a plant into a central station at once doubled the cost of working? Even the strongest opponent of municipal trading would hardly say that. He was aware that the 1·37d. covered a proportion of the standing charges due to mains to the extent that the lighting mains were being used for power supply, but in Leeds mains cost about £24 per kw. upon the basis of 1·65 diversity factor. 10 per cent. on this was £2 8s., which on a 25 per cent. load factor was about 0·25 per unit, and this was included in the 1·37d., as represented by mains. If 1·37d. were the correct costs, how was it that where coal could be obtained so cheaply by the big manufacturers, the Leeds undertaking was supplying such a big firm as Kitson's? They had power people on the mains whose consumption ran into two million units. There must be an error in Mr. Snell's figures. He had doubtless faithfully transcribed what power users had given him as their costs, but a power user was never aware of what his costs were. The power user, in making up his costs, took coal and one man's wages, but he omitted the proportion of standing charges.

THE PRESIDENT (Colonel Crompton): It would rather help your remarks if you would say what you are charging Kitson at Leeds.

Mr. HAMMOND said that he was able to say, without mentioning any names, that there was no consumer in Leeds charged less than 1d. per unit, and at 1d. per unit they were supposed by Mr. Snell's hypothesis to be supplying people who could make a very much smaller quantity at 0·59d. He did hope that the reason was that to this 0·59d. must be added many charges which did not appear on the surface. In conclusion, he could only say that the Paper came at a most opportune time, and the discussion upon it would be renewed by him with equal vigour, possibly, in the House of Commons, where some of them trusted that this year would see a solution of a very important question, and the provision for London of a bulk supply that would do great things for the biggest industrial centre of the world.

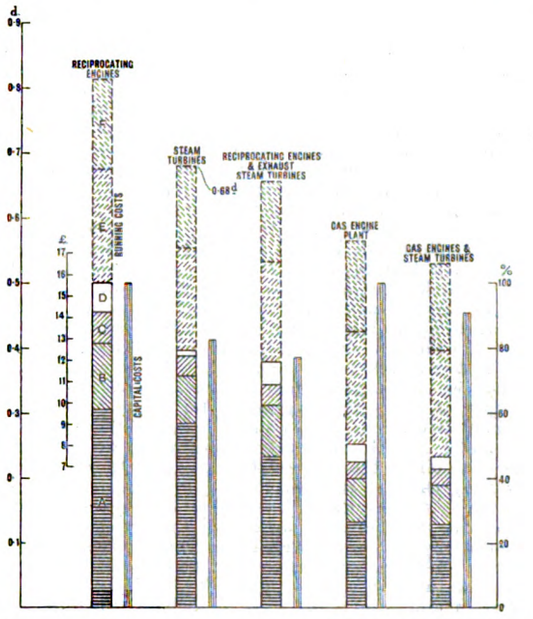
Mr. E. W. COWAN (Cowans, Ltd.), sketched the load diagram below. The area A represents "active fixed capital," and the shaded area B "inert fixed capital." The area B, the speaker regarded as representing the bye-product of the works, which, he contended, it would pay to sell for whatever it would fetch. The supply of this bye-product, he added, was limited, and its sale at bye-product prices must be correspondingly limited. If an applicant for power supply came with a demand for a uniform load from 6 a.m. to 6 p.m., as shown by the area C, the "inert fixed capital area" must now be increased by the rectangle D. As the effect upon the works diversity factor of this customer would be nil, the total area of "inert fixed capital" would be greater than before, because the area D added was greater than the area C utilised or rendered active. The proportion of the area B+D to the area A+C would, however, be

less than before, and the load factor would be improved. Consequently, Mr. Cowan concluded, the principle of charging such a consumer according to the effect of his demand upon load factor and diversity factor was sound; but he was of opinion that it did not go far enough in that it ignored another factor, viz., "the intensity of demand," by which he meant the appraisement of the value of the supply by different classes of consumers. This might, he suggested, be called the "utility factor." The utility of a unit of electricity was greater to a lighting consumer than to a power consumer, and the difference in utility was expressed by the price each class of consumer was ready to pay. He contended that it would be rational to base all charges to consumers, as far as may be practicable, upon the basis of the intensity of their demand.

Mr. G. L. ADDENBROOKE said he could go a little further than Mr. Hammond on the question of the difference between the costs in Tables I. and II., and the actual costs obtained in particular instances. But English manufacturers were not so behindhand as some people would make out, and a very large proportion of plant throughout the area would be in engines which were fairly economical, and, at any rate, were in good working order. If a manufacturer were approached under such conditions upon such calculations as Mr. Snell put forward, he at once objected to the charges for interest and depreciation on his plant. If he scrapped his plant and put in electric driving he would get nothing but the removal price, which would be a very small sum. Therefore he took up this position: "I may as well write off this sum now. Some day or other my engine will break down, and then I will come to you. In the meantime, it will not pay me unless you can supply me at something less than my present working costs and actual repairs." This had accounted in a considerable measure for the slower progress of power companies than many people would have anticipated. It was not an argument against power companies in any way because sooner or later the plant would break down, and the manufacturer would come to the power company. With regard to collieries, in the discussion on Mr. Sparks' Paper, he had given a table of prices at which he considered a power company would have to supply within moderate distances, and on this basis power could very well be supplied even in face of the figures mentioned by Mr. Sparks. He thought the matter was fairly evident from the fact that even in Mr. Sparks' case there was a very considerable length of transmission. Adding a few miles on did not cost very much extra. The very heavy capital charges which were necessary, unfortunately, in obtaining Parliamentary powers, were always a handicap to the early stages of power supply as they formed a considerable proportion of the total capital. Another point was that a station ought to be about ten times the size of its largest consumer, speaking roughly. Of course, if a consumer happened to be near, he might be supplied much cheaper, but it was a good rule to bear in mind that if a consumer was more than one-tenth the size of the station then they should look into their figures very closely before they could supply him.

Mr. C. H. WORDINGHAM said that Mr. Snell's Paper bristled with figures, but his experience was that arithmetical figures, like other figures, were not always what they seemed, and it was usually futile to discuss them. He would like to ask how many central station engineers really knew what their diversity factor was. How many knew what was the maximum demand of all their individual consumers? He could not help thinking that a great deal too much was being made of diversity factor. The important thing was the load factor; the diversity factor did undoubtedly affect the result, but he very much questioned whether the diversity factor meant anything like as much as was made out in these power company stations, of which so much was heard and so little seen. He could not conceive that the tacking together a number of different towns—very similar as they were and must be in the areas of many of the power companies—could possibly improve the diversity factor to any material extent. Where the full gain was obtained was in a rather large town, where both the central portion and the suburban or residential part could be included without having to go too far for the load, and without too great a load at the outer circumference. In London he thought the greatest possible mistake was being made in regarding it as a new problem, when there were so many companies and authorities who had sunk their money in it.

Mr. W. H. BOOTH referred to the heating of cotton mills. They had to be heated day and night and on Sundays, practically the whole year round, except a few hours during summer in the daytime. The mill was heated not only by its own machinery, but also by special steam pipes. An Oldham cotton-mill spinning 28's to 30's with 70,000 spindles, and a horse-power of 1,000, would have three boilers 30ft. by 8ft. 6in. at work, which required one fireman. If heat must be supplied to the mill, the fireman was still needed. The coal required for heating was from 12 to 14 tons a week in winter, and the heat had to be supplied from somewhere. At the Acme Mill, Pendlebury, there were two mills close to one another. One was electrically-driven by power from the Radcliffe power station of the Lancashire Electric Power Co., and the other, which was driven in the ordinary way, supplied steam to the electrically-driven mill. It was a moot point with regard to Manchester cotton mills, who was losing on the contract, the supplier of electricity or the user. But it was claimed, at any rate, in favour of the electric drive that as much as 7½ per cent. greater work was obtained, which would mean something like £500 per annum extra profits. The coal used in Oldham mills was from 1¼lb. to 2lb. per horse-power-hour, and in winter from 1¾lb. to 3lb. The consumption in summer was 37¼ tons to 50 tons per week, and in winter from 43 to 75 tons per week. This came out at about 2,500 tons, which, at 10s. per ton, amounted to £1,250. This did not agree with Mr. Snell's figures. There was another mill in Manchester belonging to some fine-spinners, which took, he was told, about 2,000 h.p. from the Manchester Corporation Stuart Street



Digitized by Google

station at considerably less than ½d. per h.p.-hour. This being so, Mr. Snell's figures must be wrong, because he showed very much higher figures for Manchester. In power supply tney were always apt to think a poor load factor meant that a consumer should be charged heavily. Mr. Snell referred to these limitations, and advised some people to spend twice as much time in docking a ship. He also referred to another method which would be fatal in Lancashire, and that was to change the dinner hour. When there were half-a-dozen people in a family living in one house and working in different mills, and having different dinner hours, he thought the old lady of the house would object.

Mr. G. W. PARTRIDGE (Engineer-in-Chief, London Electric Supply Corporation), said that after 20 years' experience of London, he did not believe there would be a diversity factor of 1·66. It would be much nearer 1·25. If this were the case it altered, as far as he could see, all Mr. Snell's calculations. Another point was that in London a great many of the factories had working hours practically the same. Table VI. gave the cost of the transmission system at £12 per kw., but this figure was very much too low. It must be remembered that in laying out a scheme such as Mr. Snell talked of, it would take a great number of years before there were very many consumers, and from his experience it was impossible to get anybody to take a supply until the main was absolutely outside his door. Even after mains were laid it sometimes took two or three years before the consumer would take a supply. Another point was that the cost of repairs and general road work in London was very much higher than in the country. Spare ducts must be allowed for in the first instance, and it would take a great number of years before Mr. Snell would get anywhere near the figure he gave. Instead of £12 for the first two or three years it would be nearer £30. The Newcastle Co. had, according to the Paper, a cost for mains and sub-stations of £26. As Mr. Snell allowed £3 for sub-stations, this left £23 for transmission system. If it cost £23 to lay mains in a district like Newcastle, he thought it would come to very much more to lay the same mains in London.

Mr. G. H. CORRINGHAM said that if the figure of 2d. per unit for lighting was correct with a lamp like the Osram, a consumer would be able to have 30 c.p. for 14 hours for one penny. This would be bound to stimulate the lighting branch. The usefulness of Table I., he thought, was considerably impaired by wages for attendance not being included. Taking the case of a 60 kw. plant out of Table I. and adding £75 per annum for wages (this was the most favourable case in the table) gave 0·17d. per unit. With regard to the Sunderland diversity factor, he would like to mention that on the Bermondsey station the diversity factor, reckoned on the same lines, came out at 2·7 against 2·4. In Table VII. the figure given for this station as the actual charge was 2d. per unit. He did not know how this had been obtained, but in the year ending March, 1906, the figure for power was 1·45, and in the last published figures it was 1·17. In Table IX. the mean rate which was given for a 20 per cent. load factor was evidently wrong, but this was apparently a clerical error, because it was neither the mean of the four preceding columns, nor was it the correct average by multiplying the prices by the number of units in the respective stations and dividing by the total. He did not think Fig. 1 was applicable, unless the annual load factor were taken into consideration. It seemed to him that if a station was at full load for 24 hours a day the fact that the loss of energy was constant was going to make a difference, as all the other curves were falling curves, both capital cost per unit and production cost per unit. Mr. Snell had assumed £12 per kw. on the basis that every 100 kw. would supply 166 kw. outside, with a diversity factor of 1·66. This assumption could hardly be credited, because they could not run without spare plant. In Bermondsey now there was room to put in 4,000 kw. The present size of the plant was 1,475 kw. The new plant could probably be installed for no greater cost than £10,000 for each 1,000 kw., and this being so he did not see where the advantage came in of having plant, say, at Barking Creek at £12 per kw. and adding transmission and transformation charges.

Mr. LEONARD ANDREWS (Key Engineering Co.) said he would confine himself to one point only, viz., to use the author's own words, "the present inability of most undertakings to meet a large demand for power at such rates as to hold their own with local plants." Other speakers had dealt with this question by attacking the author's figures as to the cost at which these local stations can produce their power, but no one appeared to have referred to the question from the other end, viz., was the figure which the author had given as low as they could hope to reach. The author himself said that he did not think there was much prospect of materially reducing this figure of 0·68d. for alternating current supply. Mr. Stott, the Chief Engineer to the Rapid Transit Co., in a Paper read before the American Institute of Electrical Engineers in 1906 on "Power Plant Economics," had pointed out that a very considerable economy could be effected by purchasing for a portion of the equipment plant that cost the minimum amount and using that for the peak of the curve and using the most economical plant possible, even though it cost more for the flat portion of the curve. Mr. Stott took five different methods of generating, viz., reciprocating engines, steam turbines, reciprocating engines combined with exhaust turbines such as were now being used at Edinburgh, gas engine plant, and gas engines combined with steam plant. The costs were plotted by Mr. Andrews on the diagram below from A to D in each case. Taking reciprocating engines at 100 per cent., with steam turbines, the estimated running costs were 80 per cent., reciprocating engines combined with exhaust turbines about 75 per cent., gas plant 55 per cent., and with combined gas and steam plant something below 50 per cent. He also gave capital cost in each case, and again taking reciprocating engines at 100 per cent., steam turbines were about 80 per cent., gas plant was very high again, and combined gas and steam plant slightly lower than gas plant alone. In order to bring these into line with Mr. Snell's estimates, Mr. Andrews had assumed that Mr. Snell had based his estimates

A. Coal.
B. Labour.
C. Repairs.
D. Oil, Waste, Water, and Stores.
E. Interest and Depreciation, 6¼ % on Capital.
F. Rent, Rates, Taxes, and Management Expenses, 5 % on Capital.

upon steam turbine plant. Taking £13 per kw., the diagram gave the capital costs of the other systems. In the case of running costs, he had also taken Mr. Snell's figure of 0·68d. per unit for turbine plant, and deducted from it 0·125d., corresponding to 5 per cent. upon the capital cost, for management, rent, rates, and taxes, and charges of that sort, and a further 0·157d. which was calculated upon the cost of the generators, mains, and transformers, assuming 20 per cent. load factor, 1·66 diversity factor, and 64 per cent. interest and depreciation. This brought the balance down to 0·4d., which he assumed to be the working charges. These had been divided according to Mr. Stott's figures into four items, A, B, C, and D, and the two sets could be compared. The result was a gain of about 22 per cent. over Mr. Snell's figure of 0·68, if combined gas engines and turbines were used instead of turbines alone. As a practical illustration of what had been done in this direction, Mr. Andrews said that he had seen a works in Germany a few weeks ago where gas engines and steam turbines were running in parallel in this way, and he was told that they were supplying power in bulk to a town about 30 miles distant by overhead mains, and were selling it there at an average price of 0·5d. per unit.

Mr. A. M. TAYLOR (Birmingham Corporation Electricity Supply Department) said that on the last occasion Mr. Snell and himself had rather misunderstood one another and as to what they each meant with regard to diversity factor. Since then he had had an opportunity of looking into the construction of Tables VIII., IX., and X., and he felt quite satisfied that he could show that these were constructed on the wrong basis. The only inference in comparing Table IX. with Table VIII. was that it referred to the station load factor, but he thought Mr. Snell must mean the consumers' load factor. On the other hand, if this meant consumers' load factor, Mr. Snell ought to have given a fifth column, showing the varying values of diversity factor with the increase in the consumers' load factor, because it must be evident that if the consumers' load factor increased, the diversity factor must go down in a station. He thought, as a matter of fact, that Mr. Snell had taken these as the station charges and the station load factor, because in Table XII., in comparing the Newcastle supply, Mr. Snell gave the columns side by side for the same load factor, and in that case it was perfectly evident that he had simply reduced the standing part of the charge per unit from the first to the second column by dividing by the diversity factor. This, Mr. Taylor

Digitized by Google

maintained, was absolutely wrong. Further, if the left-hand column in Table XII. was constructed on the basis of 0·24d. per unit for the running charge and £7·6 per kw., whereas the right-hand column is upon 0·24d. and £4·5 per kw., then the result was obtained by dividing practically by the diversity factor. In Table VIII. Mr. Snell had not at all done justice to the municipal supply concerns. In connection with Manchester, for instance, he had constructed this result upon the basis of 0·39d. running costs and £8·48 per kw. standing charge. He ventured to say that at Manchester at the present time 0·2d. instead of 0·59d. would be nearer the mark. Therefore, while the figure for the 20 per cent. load factor would not be materially altered on 80 per cent. load factor, the result was that instead of 0·69d. per unit, as Mr. Snell had got, this should be 0·54d. If, again, this was compared with London County Council supply in bulk, where the distribution charges, as had already been pointed out, were of the order of £3 per kw., the result was that they got down to the figures on a 20 per cent. to 80 per cent. load factor of 1·15d. per unit and 0·44d. per unit respectively without dividing by the diversity factor at all, which, of course, he submitted was wrong. He thought it would be seen, therefore, that justice had hardly been done to the municipal stations as against the London concerns, and if Manchester could not do their 0·2d. per unit, Birmingham would do it in the course of another year.

The PRESIDENT (Col. Crompton), in summing up the discussion, said he wished to say that long before he knew he was going to be President he had intended to discuss this dear old subject which had filled their debates so much some 20 years ago. It was the opening words of the Paper which had tempted him to discuss it, namely, "that the fundamental elements of details of design in large power stations and transmission systems are now so generally accepted that there appears to be but little to add to the available information." If the author meant by this that we had approached finality, he was sorry for the Institution of Electrical Engineers, for a great interest would leave their discussions. He himself believed they were no more near finality in this matter than we were fifteen years ago. He did not believe that the great improvements which had taken place during the last eighteen months in metallic filament lamps was going to rest by themselves. There were great possibilities of improving the thermo-dynamic efficiency of generating plant; the enormously increased use of the internal combustion engine during the last two or three years, and the spur that it had given to steam design, left us on the verge of great steps in advance. Those who would have to debate this question 15 or 16 years hence would have to face antiquation costs just as they now had to be faced, and he did not see what was the use of begging that question either in Parliament or elsewhere. He did not believe that those who started with a gigantic scheme now, would in a few years, when they had got their scheme working, be in any better position than those who now had plant working. He did not believe in huge stations; he did not believe that the Lots Road, or "Lots of smoke Road" station, as it was sometimes called, was absolutely perfection. He himself had seen private installations on the scale of a million units a year running for many years at lower figures than had been put forward by Mr. Snell. He would support Mr. Snell to the utmost in Tables I. and II., which had been so much challenged. It was a well-known fact that there were plenty of travellers for modern manufacturing firms who could produce suction gas plant and modern steam plant, and put it down under guarantee for private firms at under a halfpenny per unit, which included all charges and 10 per cent. interest and depreciation. These circumstances were what large power distribution schemes had to contend with, and these were the plants which they were so fond of pointing out that they wished to supersede. He was now speaking from the point of view of a chairman of a lighting and power company. He knew that these private plants were the enemy that had lain in the path for years. He knew of cases where suction gas plant had been put down during the last year or two, and was working satisfactorily within a few yards of one of the largest power stations in the north of England, and this fact had been mentioned over and over again in evidence in London, as one of the reasons why it was so difficult to get manufacturers to take power from outside sources in London. All those who wished to reduce the total cost of electric supply by increasing the demand for it, and filling up the blank spaces on their load diagrams, must take a leaf out of the book of those great commercial undertakings, the drapery houses. The members present all had wives or daughters, or ought to have, and they all knew the fertile subject of remnant sales. By his remnant sales the draper succeeded in disposing of his remnants, and this enabled him to sell to the public the rest of his goods at a lower price than he would be able to do otherwise. Electric supply engineers had their remnants, namely, energy for power supply, and they sold it at a penny. Mr. Snell had put down his (Col. Crompton's) company at a figure which was most complimentary, namely, a little above that which Mr. Snell said it ought to have sold at; but Mr. Snell had made a mistake there, because they sold it at a penny like everybody else. But they did not sell it to make money, but in order that a plant already existing might, under existing conditions, yield a better return. There was something else; there was a fetish or a superstition that prices must never be raised once they had been lowered. But why should that be true to electrical energy, when it was not true to coals, bread, or any other life necessity? Why should not electrical engineers vary their prices according to conditions? If conditions were extremely favourable, if a certain number of manufacturers settling down in a town increased the output, why should they not then give everybody the benefit of it, and still maintain the dividend, or reduce the burden of rates as the case might be? On the other hand, if these good conditions disappeared, if the collieries increased prices, or the prices of labour rose; if the neighbourhood became more thinly populated and works migrated into the country on account of rates or other causes, why should they not then increase their prices? Electrical engineers had allowed themselves to be driven by a sort of popular clamour. The newspapers in London had led people to believe that they had an inalienable right to electricity at a farthing per unit, but the public had nothing of the kind. Electrical supply at the present prices had been an inestimable boon to the public, and they were extremely lucky to get it at present prices. The shareholders often had a poor return for their money, in spite of the fact that the electrical engineer had done yeoman service; better in this country and in London than in any town or country in the world. He had studied this question for twenty years; he had been everywhere, and had seen all the huge stations in America. He had seen what Americanised stations could do here, and he had seen the best stations on the Continent. But we had nothing to learn from them, and we had never had anything to learn from them. We held the record in England for the coal bill, and we ought to keep it as certainly as we had the record of the *Mauretania*. He was heartily with Mr. Snell, whose Paper was a very valuable contribution to the Institution proceedings. It would be a work of reference which he himself would dip into from time to time. He wished heartily to support his figures as to the small cost of modern private plants. He could assure them that all the improvements that had taken place of late years had been to the advantage of the small plant, and not so much to the advantage of big plant, and he felt confident that the overwhelming superiority of the 5,000 kw. turbine plant was no longer to be maintained. The same results had already been obtained by smaller plant, and it was quite clear that the private manufacturer could have figures put before him which would make him hesitate to go on to the public mains unless he could have figures quoted him very much lower than had been considered possible hitherto, and which had been rendered necessary by the great cost of transmission.

Mr. J. F. C. SNELL said that after such a prolonged discussion, it would be quite impossible for him to reply fully, in the short time available, to all the points raised by the various speakers. He wanted first to make a correction. The Newcastle Power Co. had asked him to point out that in his Table XII. he gave the figures for 1907; these really were for the year ending December 31st, 1906. In order to avoid any suggestion that the Paper was in any way an advertisement for himself, he wished to point out that it was begun to be written last year, and he had at present absolutely no connection with any of the present power Bills. It would, therefore, be seen that that part of the Paper which referred to London, was entirely the free criticism of a free lance. With regard to Tables I. and II., he should be sorry if his Paper gave the impression that the figures were such that all manufacturers could obtain from their local plant. He had been most careful to show that, in some cases, wages, and a proportion of the general establishment charges, were not included. Certain of the costs were omitted because they could not be obtained, and he had shown in the results of plants at various works, in many cases from figures taken by himself or his assistants, that higher results were obtained than were shown in Tables I. and II. In these, however, all the costs were included, *i.e.*, actual capital charges, and some proportion of the general establishment charges. The figure, 0·71d. referred to, was taken from a very well-known engine works, and he knew it was perfectly correct, and it was higher than the figures in Table II., because it included a proportion, and very properly so, of the general establishment charges, and a proportion of the rating of the whole works. He would be sorry if the Paper had the effect of frightening capitalists—they appeared to be frightened enough already—but he did think it was advisable when considering the question like this, to face the truth, whatever the truth might be. Mr. Taylor had covered a number of points, and it would be unwise of him to attempt to reply to his supplementary remarks until he wrote the reply for the Journal. Mr. Taylor, however, stated that the Paper only dealt with large power users. There he was quite mistaken, because the tables quoted in the first parts of the Paper not only included direct supply to a certain proportion of large users, but also included the actual distributing charges to a number of small users, and the distributing cost—he was speaking from memory—of £30 per kilowatt were taken for the local distribution to smaller users. He had already explained that Figure 1 was corrected for diversity factor; in fact, if Mr. Taylor carefully read the Paper he would see that this was stated. Mr. Taylor had also referred to storage in sub-stations, but he was sorry to say that the cost of storage batteries had not been sufficiently reduced to enable them to be used to the extent which he personally would like to see them used. He had said in the Paper that £12 per kilowatt was applicable to large

Digitized by Google

stations, to the order of 20,000 kilowatts and upwards. They had heard that evening from Mr. Sparks that for plants of 3,000 kilowatts only he had built stations at from £11 to £15, and he was quite sure, in spite of what many critics had said, that stations of from 10,000 kilowatts upwards, could be installed for something of the order of from £12 to £14. Mr. Seabrook had referred to the Newcastle cost of £33, and compared it with £12, which was the estimate given in the Paper. But Mr. Seabrook must surely remember that the Newcastle figure included the old Pandon Dene station, and also included a further pioneer station of the power company. It was not the real cost of what the newer station of the power company would represent to-day. As to his estimate for sub-stations being too high, and that they should be reduced to one-half, all he could say was that this figure was based on practical work, and where no money was wasted. Moreover, the figures were confirmed by Mr. Rider from actual practice, and had been confirmed in the Glasgow discussion by Mr. Lackie and Mr. Robertson. Mr. Seabrook did not agree with centralisation for London, and had said that centralisation would be more applicable to the provinces. With this he could not at all agree, because in the provinces land was much cheaper than in London, and many other items were cheaper. Mr. Seabrook, in passing, had compared Tables VIII. and II., but he should not have done this, he should have compared Table IX. Table VIII. represented the actual cost of production from the works. Mr. Seabrook and others made a mistake if they thought they could lose a large number of their electric lighting units with impunity. The lighting units must always be a higher order of cost than the power units, because the much criticised diversity factor was a dominating factor in the division of costs between the power and lighting. By diversity factor he meant the sum of the maxima of different users from any station, and its ratio to the maximum demand at the station itself. This, he took, was the true diversity factor, and they would always find—at least he had always found—that the diversity factor of power users was much higher than that of lighting consumers. Naturally people all wanted their lighting nearly at the same time, and lighting consumers would have a diversity factor of one, were it not for the fact that they had theatres a little later in the evening, and that the residential and shop maxima were not simultaneous. In the case of Sunderland, the diversity amongst the smaller works supplied from the actual lighting mains amounted to 2·4; he had taken 1·66d. as the average diversity factor for industrial purposes. Personally, he believed this factor was too low, and he would be very glad indeed to find that it was, because it had such an effect upon the actual cost of production for power purposes.

Some members who had desired to speak were unable to do so owing to lack of time, and others were not able to be present. We append a *résumé* of some of the communications that have already been sent in:—

Alderman GEORGE PEARSON (Chairman of the Bristol Electricity Committee) feared that it would be many years before small towns would be able to command the services of large power companies in their immediate vicinity. Assuming, however, a power company to be in existence, and the charges to be as shadowed forth by Mr. Snell, he thought it would be an advantage to the small towns to accept the services of such companies rather than generate for themselves. But he thought that a power company was never likely to be of great service to the larger municipalities, nor did he think it possible that a power company could exist except in the midst of a thickly populated district. He was inclined to agree with Mr. Snell that the estimated distance over which power companies could economically supply had been somewhat overstated. The Bristol Corporation were arranging to supply eight miles from their station, but he would think twice before agreeing to supply at double that distance however high the voltage might be fixed.

MR. W. C. P. TAPPER (Chief Electrical Engineer, Stepney Borough Council) described the figures in Table VII. not only as incorrect, but as utterly meaningless, owing to the absence of any reference to the load factor and diversity factor assumed by the author in their calculation. They should have been given as so much per kw. per annum, and so much per unit, as this took full account of the load factor. The charges for Stepney would have been correctly stated as £4 per kw. per annum, plus 0·5d. per unit, with a maximum charge of 1d. By both reckoning the cost and charging the consumer on this basis, there could be a profit on both items, and thus there is no risk of the consumer obtaining his supply below cost price. At Stepney for a particular year, the total cost of production was £2·7 per kw. per annum, plus 0·495d. per unit, and the charge to the consumer of £4 and 0·5d. was therefore a safe one.

Mr. A. W. HEAVISIDE wrote of "those wonderful factors, the power factor, the load factor, the diversity factor, the intensity factor, the determinate factor, and the malefactor," which, he says, are described abroad as the outcome of the British savages' desire for a formula for every problem in life. Admitting that a number of uneconomical systems over small areas used for special, not general, application, was undesirable, he opposed on general public grounds, permission being given to any amalgamation scheme of existing undertakings. He would suggest as the best scheme the dividing up of existing undertakings into such groups as would secure cheap production and distribution, and leaving each group under one management. Then at stated intervals of five, seven, or ten years a balance sheet should be drawn up by an independent body of experts, comparing the results of that period. Should such an examination show marked advantages in the working the administration of one group as compared with another, it would become the duty of the less successful groups to fall into line, and gradually bring their systems up to a higher standard of efficiency. Provision, he thought, should also be made for an emergency service, by means of a ring main all round London, by which one group could assist another group when in need.

Mr. A. H. SHAW (Chief Electrical Engineer, Ilford Corporation) did not think it fair to compare the cost of power in the Newcastle and Sunderland district with the cost of power even from a large bulk station like that proposed to be erected in London, as the costs of the latter were bound to be higher. He thought he was right in stating that the large majority of the possible 400,000 h.p. in London was made up of a large number of comparatively small consumers instead of a comparatively small number of very large consumers, as on Tyneside. He thought also, that the costs of the Lots Road station had not been altogether as low as were anticipated. He also made the same point as we did in our editorial comment last week, viz., that if the charges in Table VII, referred to as being "correct," had been charged in the first instance, they would still be incorrect as the load upon which they are based would not have been obtained at this price; and by the same method of calculating it would have been necessary to fix the price at the highest charge possible, in which case no power load at all would have been obtained. Mr. Shaw's letter continued: It is also incorrect to compare these charges with the "probable" charge from a power supply company. The former charges include all distribution losses and establishment losses, and the average consumer is only a small one whereas the latter is the estimated average charge of the L.C.C. for a 20 per cent. load factor for a bulk supply. Mr. Snell recommends that transmission systems should be so arranged that works requiring over 100 kw. should be supplied from their own static sub-stations. When I raised this point with the officials of the L.C.C. in regard to their power Bill, I was informed that they would not be prepared to supply a local authority in bulk at more points than one in any district until such sub-stations had a load of between 2,000 and 3,000 kw. Referring next to capital expenditure, Mr. Shaw said that at Ilford, the cost was now about £46 per kw., and with the further extensions now in hand it would shortly be reduced to about £38 per kw., about 50 per cent. of which is expenditure on mains. He believed that the solution of this matter was not a large bulk supply company, but a scheme of linking up various stations, whether companies' or local authorities'. The larger and more economical stations could then be extended as required, supplying current at low ratio to the smaller stations, which would only be run on the peak load. All who were concerned should do their utmost to press the Board of Trade to push forward with their Electricity Supply Bill in the coming session.

Mr. G. H. COTTAM (Chief Electrical Engineer, Hampstead Borough Council) said it would not be fair to those who have borne the burden and heat of the day, and who had buildings and land capable of considerable extensions, if they were to be prevented from extending their plant. Nor would it be fair that promotors of new companies should be exempt from the County Council Building Acts while the local authorities were still to remain under them. In another scheme it had been asked that their bulk supply mains should be exempt from local rates and taxes. One company made a great show in advertising their price for power at 0·22d. per unit, which, said Mr. Cottam, when it "came to be looked into at our load factor, meant for converted energy at our switchboard one penny per unit, we having to supply, house, and maintain the converting machinery; and it was they who asked exemption from rates for their mains!" Mr. Cottam then referred to the ill-success of some of the power companies, mentioning particularly the Midland and South Wales companies. Within the last week he had been told that the Durham Collieries Electric Power Co. were selling at ¾d. per unit, yet their total costs were 2¼d. Referring next to the Lots Road station of the Underground Railways Co. of London he said that it is rumoured that the cost per unit of their energy for power in Hampstead is greater than the local authority charges them for lighting their station. He was also told that the Neasden power station of the Metropolitan Railway could easily beat Lots Road. In conclusion, he contended that the power schemes which had been put before Parliament in recent years had done considerable injury to the industry in general, making it difficult to obtain money for extensions, and preventing would-be consumers from coming on, because they thought that by waiting they would obtain energy so much cheaper.

Mr. F. B. WOODHOUSE (Engineer and Manager, Yorkshire Electric Power Co.) thought that Mr. Snell had generalised too freely in making his comparisons, but on the broad principle that the smaller and older stations cannot supply large power users at competitive prices, he was in full agreement with him. With regard to Mr. Snell's estimates, Mr. Woodhouse wrote: In Section 1 a large undertaking's supply may be divided into

Digitized by Google

two classes, (1) Bulk supply, *i.e.*, for redistribution, for lighting and small power users; (2) supply to power users direct. The first class of customers must have electricity, and the competitive prices at which power may be bought are easily determined. In the second class, however, the problem for the power user to decide divides itself into two parts, the first whether electrical energy is preferable to mechanical transmission for his works; the second, which depends on the answer to the first, what is the competitive price? It is obvious that if mechanical transmission is preferable the supply would be utilised in one motor, but that if the reverse is the case then a number of motors would be used—that is to say, the competitive price would be higher. An analysis of the average costs of Table I. shows Mr. Snell's estimate as equivalent to a charge of about £3 6s. per kilowatt per annum, and 0·5d. per unit. It should be remembered that by far the greatest part of a power supply will be to consumers having load factors between 10 per cent. and 30 per cent. Between these limits the figures seem fair ones, but they cannot be considered as anything but a first approximation. One power user with a 25 per cent. load factor may require to run his plant day and night continuously; another may only require to run for definite hours daily, and will shut down completely the rest of the time; their costs may, therefore, differ considerably. Referring to the next part of the Paper, Mr. Woodhouse thought that the comparison of the pumping costs on a graving dock and pontoon were made on a false basis, that of a ship tonnage. It is obvious that in the dock a large ship will, in proportion to its draught, displace a larger quantity of water from a full dock than will a small one, and therefore leave less to be pumped. The comparison should be made on the basis of pump horse-power hours. He adds that the price given for the public supply would be an absurdly low one if capital charges were considered. The load factor of the pontoon pumps would in practice not exceed 1 per cent. per annum, but with this load factor it was not surprising that clashing with the peak rarely occurred. The average water horse-power in the electrical case was 168, in the gas 96, equivalent to, say, 160 i.h.p. How did two 40 h.p. engines do this? If there is an error here, then the capital charge would be considerably increased. Coming next to paper mills, Mr. Woodhouse says: Any calculations based on h.p.-hours of steam plant must be looked on with suspicion. I cannot accept Mr. Snell's ratio of costs per unit and per h.p.-hour. The ratio of kw. to e.h.p. is 1·41 : 1·05, whereas Mr. Snell assumes the ratio as 1·41 : 1, or the generator has an efficiency of 105 per cent. He could not agree with Mr. Snell's statement that a cable and distributing system sufficient for a large power scheme can be laid down at a cost per kw. equal to that of the generating station, but as I had endeavoured to show in my recent paper, the advantages of centralisation would allow a considerably greater proportion of the total costs to be expended outside the station.

Mr. L. H. HORDERN (Manager, Westminster Electric Supply Corporation, Ltd.) said that not a single one of the big power schemes had yet proved itself a financial success, and he hoped that this would be the last year in which it will be proposed to introduce into London such a peculiarly unsuitable method of supply. We must look for safe progress on evolutionary, not on revolutionary, lines. Turning next to the details in the Paper, he pointed out, as an example of the importance of diversity factor, the case of lifts. Individually, these have a very bad load factor, but give collectively a very good load factor to the supply station. Under any scale of charging which involves a high rate per kw., and a low rate per unit, the cost of working lifts electrically would be prohibitive, and he believed that in London a flat rate was the correct system of charging for power, and not the scale suggested by power companies. These scales might suit the scattered districts for which power companies are the only possible system of supply, but they seemed, said Mr. Hordern, to be as unsuited to a closely-populated district as are power companies themselves. Mr. Hordern, whose letter is highly critical throughout, returns to the general question in concluding, as follows:—"In conclusion, we are advised that by hook or by crook a large power station must be erected, but that it is essential it should not prejudice present capital: the omelette must be made without even cracking an eggshell. Even suppose this impossible feat achieved, we are not told why we should go to the new station for our supply. We are responsible for maintaining a supply each in a certain area; that we are purchasing our supply from another company at a fractionally lower rate than we could make it ourselves would not divest us of responsibility for failure. Who again is going to place the success or failure of their undertaking in the hands of another company, which, on its own showing, would have to cut everything very fine to make a profit, and whose plant or mains might consequently break down sufficiently frequently to interfere with business? Is it the apparently solid foundation provided by our London fogs which induces our visitors to build so many castles in the air? The generation and supply of electricity must be in the same hands if a company is to control its own destiny, and to achieve the best results the whole of the supply in any district should be given from one source. Small areas where this is the case are in a better position than large areas where generation and supply are separated, or where power and light are supplied by two different concerns. A power company operating at Westminster could not supply the large consumers cheaper than my company, and it could not supply the small consumers at all, while if it were merely supplying current in bulk we should require to be able to prevent it economising at the expense of reliability.

Letters have also been received from Mr. J. H. Bowden (Poplar Borough Council) and Mr. W. B. Esson, but we are compelled to hold them over, together with the report of the discussion at Glasgow, until next week.

ELECTRICAL SCIENCE

British and American

A Null Method of Measuring Ionisation.—The rate of leak method customarily used in the measurement of the ionisation produced in a gas by any agent has many disadvantages. For example, if the agent be a rapidly transforming radioactive substance the time taken to make a reading of a sensitive electrometer is much too great and the movements of the needle are much too sluggish to allow of accurate study of the rate of decay of activity. In the December *Philosophical Magazine* J. S. Allen explains a method of measuring wherein the task of the experimenter consists in keeping the electrometer needle at rest and in reading divisions on a ruler. It is in principle similar to a method, which was not a zero method, used by Bronson. Two ionisation chambers are provided. One consists of two parallel horizontal metal plates, on the lower of which the radioactive matter under test is spread. The other ionisation chamber is similar, but differs in that its lower member is a shallow brass box, covered with a lid that can be slid horizontally along the line of a diameter of the box. The floor of the box is covered with a uniform layer of uranium oxide, and by sliding the lid it is possible to vary at any desired rate the conductivity of the gas in the ionisation chamber. The lower plates of the two chambers are connected respectively to the end terminals of a battery of cells, whose middle point is earthed; the upper plates are connected to the same pair of quadrants of an electrometer, whose other pair is earthed. If at every moment the current from the positive end of the battery through the gas ionised by the test substance is balanced by the current allowed to flow through the uranium chamber from the negative end of the battery, then the electrometer needle will remain at zero. With a substance whose activity is varying the lid of the box must be moved continuously to maintain the balance, and the readings to be taken are those of the time and of the position of the lid on an arbitrary scale. This scale must, of course, be calibrated by the rate of loss method. The calibration curve for a circular box shows that the ionisation increases very rapidly at first as the lid is opened and then more slowly.

Continental

Flames as Rectifiers.—A. Cathiard points out in the *Comptes Rendus* for January 6th that a flame in which no solid conductor is suspended may be utilised for rectifying alternating currents. It is only necessary to use one electrode having a much smaller area than the other. The current then passes only from the larger to the smaller electrode. He uses by preference graphite electrodes in a coal-gas flame, the smaller electrode being a pointed pencil 5 mm. in diameter. From 2,000 to 10,000 alternating volts are applied at forty periods per second. The distance between the electrodes may vary from 5 mm. to 10 cm. without altering the phenomenon, and the electrodes may be at different levels. The continuous current obtained is feeble, never surpassing 30 milliamperes. But it produces distinct electrodeposition in a voltameter. When the current is made stronger, it becomes alternating. There is a bright arc within the flame, and a transport of solid carbon. Even when the current is continuous a feebly luminous arc is seen, whose end moves rapidly about on the larger electrode. When the voltage is reduced, the current also decreases, and finally the rectification is reversed, giving rise to Hanckel's phenomenon. The author has not yet obtained oscillograph curves from the flame current.

Positive Rays.—The Doppler effect in canal rays turns out a most valuable and suggestive phenomenon with regard to the mechanism of radiation. Its discoverer, J. Stark, makes some interesting deductions from it in the *Physikalische Zeitschrift* for December 15th. The displaced canal ray spectra are emitted by positively charged atoms. This is generally agreed. But the author, in spite of Wien's objections, also maintains that they are not emitted below a certain minimum speed. That is why there is a gap between the undisplaced line and

Digitized by Google

the displaced fluting. The displaced series spectra are only emitted when a positive atom impinges upon a neutral atom. The impact must be in resonance with the natural period of the radiating electron. Radiant energy is then liberated at the expense of the perfect elasticity of the impact. The necessary speed is greater in diatomic than in monatomic gases. The author answers the question: Why is no light produced by the impact of the α-particles of radium? The reason is that they are too swift. They traverse an atom in 10^{-17} sec., which gives a wave-length 100 times too small to be discernible. Besides the displaced radiation, there is also a stationary radiation, due to the impact of electrons on positive atoms, and the ordinary thermal radiation, which produces a symmetrical broadening of the spectrum lines.

Artificial Emeralds.—F. Bordas has already shown that the colouring of corundum and aluminides generally by radium is not a chemical process, since it is unaffected by immersing in liquid nitrogen. It is certainly not an oxidation. In the *Comptes Rendus* for January 6th the same author studies the effect of prolonged heating upon sapphires and topazes coloured by radium. Temporary heating has no effect, but if the crystals are floated for three hours on a molten alloy of lead and tin and covered with asbestos tissue they begin to lose their colour, and after four hours they return to the state they were in before they were exposed to radium. Prolonged heating to several hundred degrees C., therefore, reverses the colouring action of radium. This observation enables us to control the tinting process with great nicety. The author believes that all Oriental emeralds were originally blue sapphires, which acquired their green colour by the admixture of yellow due to radium. Emeralds may be produced artificially from sapphires in this manner. But the resulting tint is not always of the right shade, and can be improved by heating. The α-rays are inactive in the colouring process, since they are intercepted by glass. The author proves that the β or cathode rays are equally inactive, and concludes that the γ-rays (*x-rays*) of radium produce the colouring.

Magnetism and Specific Heat.—Pierre Weiss has discovered an interesting relation between magnetic intensity and specific heat. He points out, in the *Comptes Rendus* for December 30th, that the discontinuity observed in the magnetisation of iron, nickel, and magnetite at certain high temperatures is exactly paralleled by similar discontinuties in the specific heat, and gives a qualitative and quantitative explanation of this fact. When a substance is magnetised, it possesses a certain internal volume energy of magnetisation, expressible as to product of the "molecular field" and the intensity of magnetisation. It equals, in fact, $\frac{1}{2}H_m I$ ergs per cc., or $\frac{1}{2}nI^2$, where H_m is the molecular field, I the intensity of magnetisation, and n a constant. Now I decreases on heating, and makes a sudden drop at the temperature at which demagnetisation sets in. There is, therefore, a supply of internal magnetic energy which becomes free, and reduces the specific heat. This energy of demagnetisation equals $\frac{1}{2J}\frac{d}{nd\mathrm{I}^2}$, where J is the mechanical equivalent of heat. It can be calculated from the curves of susceptibility, and comes out equal to the drop in the specific heat, as the author proves from the data supplied by Curie and Pionchon respectively. The energies and temperatures agree within about 10 per cent.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

LAST Friday evening's lecture at the Royal Institution was given by Professor T. E. Thorpe, F.R.S., upon "The Centenary of Davy's Discovery of the Metals of the Alkalis." The lecturer commenced with an interesting historical introduction, in which he referred to the foundation of the Royal Institution in 1799. The Institute was founded with the intention of ameliorating the condition of the working classes and for the material benefit of mankind. However, although founded to help those who could not help themselves, in the first years of its existence it was in anything but a flourishing condition, and nearly came to a premature end from want of sustenance. But the appointment of an ungainly youth "with a small brown head" in 1801 resulted in an astonishing revival, and henceforth the Institution was destined to take a leading part in the scientific achievements of the country. It is interesting to note, as we have before pointed out, that Davy's first lecture dealt with galvanism, the galvanic pile of volta having only been discovered in the previous year. Davy was evidently fascinated by the electrical phenomena, but although he showed that the reason for Nicholson and Carlisle, when they electrolysed water, obtaining acid at the positive pole and alkali at the negative pole, was due to impurities, and although he enunciated his electric theory of chemical combination, he had had little time to work at the subject he had at heart. The first actual account of his discovery of the alkali metals is to be found in his laboratory note book, and is dated October 19th, 1807; a copy of this page was thrown on to the screen. The lecturer then gave in considerable detail the account of the discovery by lavish quotations from the original Paper of Davy. Finally a short account of the present-day process for manufacturing sodium from fused sodium hydroxide was given. Dr. Thorpe said that perhaps Davy's greatest discovery was his discovery of Faraday. Davy discovered the method of obtaining the alkali metals by electrolysis, but it is owing to Faraday's electrical discoveries that at last it has been found possible to manufacture sodium on an industrial scale by electrolysis. In 1890 the price of sodium was 8s. per lb.; to-day it is 8d. The present annual output is estimated at about 5,000 tons. The lecture was illustrated by a number of interesting photographic slides showing the works of the Castner Kellner Co. at Weston Point and at Walls End.

We learn that on January 7th the furnace house of the Notodden Works in Norway, where nitrates are manufactured from atmospheric nitrogen, was burnt down. The fire broke out at 3 o'clock in the morning in the electrical portion of the works, probably from a short-circuit. The fire brigade managed to save the buildings which were in the neighbourhood of the furnace house, and it is therefore hoped that it will not be long before the works can be restarted. The damage is estimated at 150,000 kronen (about £8,250). It is interesting to note that, owing to the great success of the process, the capital of the company stands at a considerably enhanced value.

In the *Zeitschrift für Elektrochemie* of January 17th, Bernh. Neumann writes upon electrometallurgy in aqueous solution. He commences with a study of the work done during the last half-year upon the electrolytic refining of copper. Incidentally it is mentioned that, in 1906, 368,137 tons of copper were electrolytically refined, and for the first eight months of 1907, 241,000 tons (the numbers probably refer to short tons of 2,000 lb. each). In America, 85·7 per cent. of the copper produced is refined by electrolysis.

In France, the Société de Cuivre in Eguilles have a refinery in which two tons per day of refined copper are produced. The manufactory in Givet produces seven tons, and the Elmore Works at Dives turn out 12 tons per day. In Australia, the Electrolytic Refining and Smelting Co. has been formed, with a capital of £150,000, to refine imported copper and also copper produced in Australia.

Interesting information as to the loss owing to the cathodes dissolving in the electrolyte is given. The solubility may vary from 0·2 to 1 per cent. This may in part be due to excess of iron salts being produced in the electrolyte as the anodes pass into solution. Owing to the circulation of the electrolyte, and also to electrolytic action, the ferrous iron becomes converted into the ferric condition, and the ferric sulphate then reacts with the deposited copper thus:—

$$Cu + Fe_2(SO_4)_3 = CuSO_4 + 2FeSO_4.$$

By careful insulation the loss of current through leakage may not be more than 1 per cent, but at least 5 per cent. is lost through shorts between the electrodes. The current efficiency is given as between 90 and 95 per cent.

The process of Cowper-Coles for obtaining seamless tubes by rapid rotation of the cathode, and that of Elmore, in which a burnisher is employed, are well known, also the method of Harrison, in which the electrolyte is injected against the cathode. All these processes aim at working with high current densities and obtaining a smooth and tough deposit. According to the German patent 175,479, the same results can be obtained by using a moderate speed of rotation and having a fine insoluble powder, such as kieselgur, in the electrolyte (20 kg. per 100 litres) (ELECTRICAL ENGINEERING, Vol. I., p. 1015).

One of the most difficult problems yet to be solved is the treatment of copper ores in such a manner that the copper may be directly obtained pure without it being in the first place necessary to smelt it. L. Anderson (American patent 862,871) suggests treating the ore directly with hydrofluosilicic acid and then electrolysing the copper fluosilicate so obtained. R. Lamp (American patent) hopes to solve the problem by treating the crushed ore in revolving drums with sulphurous acid, and L. Juman (German patent) treats the roasted ore with a solution of ammonium sulphate, ammonium sulphite, and ammonia. After driving off the excess of ammonia the mixture is treated with sulphurous acid, and the double salt, $CuSO_4$, Cu_2SO_3 so obtained is dissolved in sulphuric acid and electrolysed. We are afraid that none of the methods will turn out commercially successful, but it is as well to record them, because there is a wide field open for research in this direction.

In connection with the electrolyses of gold cyanide solutions, Douglas Lay finds that if the cyanide solution contains free alkali, that it is then only very slightly decomposed by the electric current. For example, in one case where no alkali was added, 30 per cent. of the cyanide was decomposed, but in another case, where free alkali was added, only 0·03 per cent. of the cyanide was decomposed. This, of course, is important, because if the decomposition is very slight the solution after the gold has been removed can again be used to leach out fresh quantities of tailings.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Jan. 16th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from from abroad.

1906 Patents

20,928, THE BRITISH THOMSON-HOUSTON CO. (*General Electric Co. of New York*). This specification relates to the control of alternating-current motors of the commutator type, and its object is to provide suitable means for braking such motors. This consists of impressing on the field a voltage ninety degrees out of phase with the voltage of the supply. This produces a current in the field in phase with or in opposition to the source of supply, so that the induced armature voltage may practically be in opposition to the source, thus ideal conditions for no load may be obtained. The reactance of the armature circuit of the motor is very much greater than its resistance, so the current lags by a large angle behind the electro-motive force. The induced armature voltage must be varied in order to vary the braking effect, but if the resultant voltage is to be maintained at all times ninety degrees out of phase with the line voltage, the induced armature voltage must vary simultaneously in amount and phase, so that the line voltage, induced armature voltage, and resultant voltage will form a right angle triangle. The invention also supplies to the field of the motor a current of proper phase and magnitude to induce in the armature a voltage which with the voltage of the source, produces a voltage ninety degrees out of phase with the voltage of the source, and maintaining the phase of the resultant voltage fairly constant. Four claims, two figures.

29,174, H. LEITNER. This specification relates to improvements to electric motors, designed to be driven by a fluctuating source of direct current supply, as obtained in traction circuits, and the object is to make a motor the speed of which will remain practically constant whatever the fluctuations of the voltage may be. This is accomplished by making use of a constant or approximately equal E.M.F. in opposition, but inferior to the exciting voltage of the shunt field circuit of the motor. This E.M.F. may be obtained by a battery or dynamo, and by varying the opposing E.M.F., "over-compensation," that is, running faster at low voltages, or any degree of under compensation can be arranged for. One claim, one figure.

29,584, BRITISH THOMSON-HOUSTON CO. (*General Electric Co. of New York*). This relates to circuit controlling devices which automatically open an electric circuit in case of overload, and also to devices to prevent the closing of the switch when there is an overload on the circuit. The method employed consists of two automatic circuit breakers connected to the circuit and having a common operating means, so that either may be closed and the circuit completed on closing the other. In case of over-load upon the circuit, the circuit breaker which was first closed will be automatically tripped and open the circuit, so that it is impossible to keep the circuit closed if the overload remains. Four claims, seven figures.

1907 Patents

793, W. D. KILROY & EVERSHED & VIGNOLES. The specification relates to an automatic electric starting switch, consisting of an electro-magnet, having pole pieces adapted to co-act with an armature, movably arranged, relative to the poles, and also with a rotary Foucault brake device, adapted to be rotated by the armature, a series of contacts for resistances or other devices, and a movable contact arm is moved in opposition to a mechanical restoring force by the armature over the resistance contacts when the electro-magnet is energised. Three claims, four figures.

3,908, THE SUNDERLAND FORGE & ENGINEERING CO., LTD., & W. BLAIR. This relates to electric cranes, winches, &c., fitted with hand or foot power brakes, and provides an improved interlocking gear and controller returning means by suitable links connected at one end to the brake lever, and which engage at their other ends suitable guides, arranged at either side of the controller spindle, having projections which engage and disengage the controller lever. When the brake is in the "off" position the links are in such a position that the projections are clear of the controller lever, and the latter can be operated in either direction, but when in the "on" position and the brake is operated the projections cause the controller lever to return to its normal position. Two claims, three figures.

6134, THE BRITISH THOMSON-HOUSTON (*General Electric Co. of New York*). This is a block signal system for electric railways, in which the track rails are electrically continuous, and the signal circuits are supplied with current from a supply of alternating current entirely separate from that supplying the power circuit, having the power circuits permanently closed, but the supply circuits for the signal currents to each block normally open. An approaching train has the means of controlling and closing the signal supply circuit of a block ahead of the train, so the signal may be cleared and held clear until the train enters the block. In this system inductive windings cross connect the rails at both ends of each block, and form with the rails a permanently closed track circuit for each block. The connection between the circuits of adjacent blocks are adapted to form a return path for the power current, and means are provided by which a moving train produces an alternating current in a track circuit ahead of the train, and a signal controlling device for each track circuit responsive to the alternating current when supplied to it. Four claims, one figure.

8462, G. MARCONI & MARCONI'S WIRELESS TELEGRAPH CO., LTD. In this invention, instead of using a spark or arc in the oscillating circuit of a wireless telegraph transmitter, the current is caused to discharge across a small gap at the periphery or near to it of a suitable insulated disc or sphere which is caused to revolve at a high speed between two fixed balls, very close to its periphery. These balls are placed in a circuit containing a condenser and an inductance of suitable values. Each plate of the condenser is also connected to the poles of a continuous-current machine producing a sufficiently high E.M.F. to cause the current to bridge the small air-gap between the disc and the balls. In the connections between the condenser and the C.C. generator, resistances of suitable value are placed. A conductive connection is made between the circuit containing inductance and condenser and the transmitting antenna, whose period of oscillation must be brought into resonance with the period of the oscillating circuit. The receivers should contain a responsive oscillation circuit with as little damping as possible. Four claims, two figures.

10,259, LE TALL (HEWITT). This specification relates to improvements in wireless telegraphy apparatus, and particularly to a new form of radiating circuits. One of the purposes of this patent is to secure a field of force having primarily a direction, such that the direction and space distribution of the magnetic and electro-static lines of force with respect to the length of the generating conductor, or radiator, and tend to lie in the radial planes passing through the axis of the radiator and the electro-static lines tend to lie in planes at right angles to the axis of the radiator. Any suitable system of primary or exciting circuit is provided, with a radiating circuit comprising a series of two or more coils or solenoids having a common axis and disposed in a vertical direction. These can be connected in multiple, and so proportioned as to produce a resulting vertical straight line. A sufficient number of coils are employed, so that the electro-magnetic and electro-static lines will be sufficiently distributed in space, insuring an efficient radiation. By connecting the coils in the same manner as in auto-converters, and each having a capacity, and inductance equal to one-quarter of a wave-length, and having one end earthed, they will maintain a more intense field and consequent effect. One claim, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

24,448, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric motor control apparatus.

27,358, HAMLYN. Automatic electrical circuit breakers of the loose handle type.

1907 Patents

98, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric transmission systems.

155, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Incandescent electric lamps.

521, PEARCE & WALTON. Inclined carbon arc lamps.

1,278, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Operating mechanism for electric switches and other purposes.

1,301, CLIFT. Electrical ignition devices for internal-combustion engines.

4,363, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Processes of insulating electric conductors.

4,802, POULSEN. Signalling in wireless telegraphy.

8,286, BRITISH THOMSON-HOUSTON CO. & DAWSON. Rotating members of dynamo-electric machines.

22,634, HOMMEL.—Ignition devices for internal-combustion engines.

CONNOLLY BROS. LTD.

BLACKLEY, "PEAR DROP" BRAND. **MANCHESTER.**

INSULATED WIRES AND CABLES
Of all Descriptions.

NON-INFLAMMABLE. INDIA-RUBBER SOLUTION.

TRADE MARK.

SOLE MAKERS OF BLACKLEY TAPE.

TENDERS INVITED.

EDINBURGH CORPORATION.

THE LORD PROVOST, MAGISTRATES, AND COUNCIL invite Tenders for the following work at M'Donald Road Electricity Supply Station.

EXTENSION SWITCHBOARD PANEL.

The Specification, Form of Tender, General Conditions, and Drawings can be obtained from the undersigned on and after Monday, 27th January, on payment of a deposit of £2 2s., which will be refunded on receipt of a *bona fide* tender, and on the return of the Specification, General Conditions, and Drawings.

The Specification, General Conditions, and Drawings can be seen at, but not obtained from, the office of Sir A. B. W. Kennedy, 17 Victoria Street, London, S.W.

Tenders, on the prescribed form, and enclosed in sealed envelopes endorsed on the outside with the Title of the Specification, must be sent to the Town Clerk, City Chambers, Edinburgh, not later than Monday, 10th February, 1908.

The Council do not bind themselves to accept the lowest or any offer.

FRANK A. NEWINGTON,
Engineer.

Electricity Supply Station,
Dewar Place, Edinburgh,
20th January, 1908.

WANTED.

GLOVER'S ALMANAC.

THE Editor will be pleased to receive original, humorous, or instructive Anecdotes, Experiences, Verses, Photographs, or Sketches of interest to electrical men.

Literary matter not to exceed 250 words.
Illustrations to be published 4" wide × 3" deep.
Minimum remuneration: Half-a-guinea.
Higher rates for special items.
Payment on acceptance.

Matter accepted will be reproduced in the 1908-9 Almanac, which will be issued to customers and friends in June.

Address before February 14th,

EDITOR, ALMANAC, GLOVER'S CABLE WORKS,
TRAFFORD PARK, MANCHESTER.

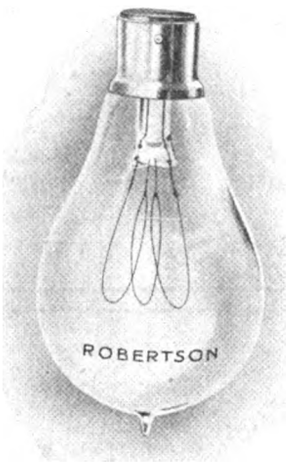
(*Small Advertisements are continued on page* vii.)

Binding "Electrical Engineering."

Binding Covers for Volumes I. and II. of "ELECTRICAL ENGINEERING" (January—June and July—December, 1907) can be supplied in strong dark red Art Linen, with strengthened back and corners. Price 2s. each; post free 2s. 4d.

Readers can have their volumes bound by their own booksellers or may send their numbers with Index, to us Carriage Paid, with the reader's name and address. The volumes will then be bound and returned to any address in the United Kingdom, Carriage Paid, for 4s. 6d. Missing Copies supplied at 6d. each. Remittances should be sent under separate cover.

Vol. I. or Vol. II., bound complete, will be sent to any address within the United Kingdom for the price of 17s. 6d. post free (Colonies or Abroad, 18s. 6d., post free); the two Volumes for £1 10s. 6d. (Colonies or Abroad for £1 12s. 6d.).



Orders with remittances should be sent direct to

THE KILOWATT PUBLISHING CO., LTD
203-206, Temple Chambers
LONDON, E.C.

ROBERTSON

ELECTRIC LAMPS

British-Made Throughout.

NOTED FOR:—
Long Life. Brilliant Light.
Low Current Consumption.

Advertising Literature and Novelty Cards supplied with Customer's Name and Address.

CATALOGUE CORNER
Latest Issues:—
1209. January No. of "General" Electrical Progress.
F 1218. Fittings and Glassware for "Osram" Lamps.
E 1227. "Flamgold" Arc Lamps.

REG° TRADE MARK

The General Electric Co., Ltd.,
Head Office: 71 QUEEN VICTORIA ST., E.C.
Branches: BIRMINGHAM, MANCHESTER, NEWCASTLE, GLASGOW, DUBLIN, BELFAST, CARDIFF, &c., &c.

Telegrams: "Destructor." Telephone: 2006.

"HORSFALL"

Codes: A B C (5th Edition) and Lieber's Standard.

DESTRUCTORS

BRUSSELS, BROMLEY, BRADFORD, ACCRINGTON, PAISLEY, SWANSEA, FULHAM, WESTMINSTER, BLACKPOOL, SOUTHPORT, and over 100 other Cities and Towns.

PATENT MELTING OF METALS PYROMETERS.

CLINKER UTILIZATION:

CRUSHERS AND SCREENS.

(Cox & McTaggart's Patent) Preparing Clinker for Filter-Beds, Concrete, &c.
In use at Bradford, Leeds, Accrington, Newcastle-on-Tyne, Paisley, Ramsgate, Tottenham, Swansea, Bloemfontein, &c.

CLINKER-BRICK MACHINERY (SCHULTHESS PATENT SYSTEM)

for manufacture of Building Bricks from Destructor Clinker.

MORTAR MILLS, Suitable for permanent works.

Our "Ball-Bearing" Mortar Mill takes half the power of any other Mill.

FORCED DRAUGHT FURNACES

For Boilers of all types; Raising Steam from low grades of fuel, refuse, &c.

Quotations for Erection complete, or F.O.R., on receipt of full particulars.

HORSFALL DESTRUCTOR CO., LTD., Park Row, LEEDS.

LOCAL NOTES

BARNES: *Tantalum Lamps for Public Lighting.*—The Electrical Engineer having reported that the tests of tantalum lamps for public lighting had proved highly satisfactory, the Council have resolved to renew all Nernst lamps where the lamp bodies give out during the next month, with tantalum lamps. A detailed report is to be prepared by the engineer of the costs per annum of the several types of lamps.

BOLTON: *Proposed Parliamentary Bill.*—Bolton Town Council at a special meeting, held on the 15th inst., decided to drop its proposed Parliamentary Bill, in view of opposition to the proposed construction of tramways in the Hulton district.

BRIGHTON: *Electricity Works Danger.*—The attention of the Brighton Corporation has again been called to the fact of the weakening of the east beach in front of the electricity works, which has become a source of danger. It is very important that the immediate attention of the Corporation should be given to this matter.

BUENOS AYRES: *Electric Supply Agreement.*—The *Review of the River Plate* states that the Compania Alemana Transatlantica de Electricidad have approved the ad referendum contract made with the Buenos Ayres Municipality. The contract, which will now be submitted to the Council, provides that the company has the right to work the industry until the end of 1957, at which time all the stations, machinery, plant, &c., will become the property of the Corporation.

CHISLEHURST: *The Council and the Electric Light.*—The Chairman of the Chislehurst Urban District Council, at a meeting of that body on the 15th inst., reported having interviewed the manager of the Chislehurst Electric Light Co., with regard to the cost and poor quality of the light provided. The manager is reported to have stated that owing to the scattered positions of the consumers it was impossible to reduce the prices, as they were only paying the shareholders 3 per cent. dividend on their investments. He recommended the use of the new metallic filament lamps. The chairman said he had tried the lamps, and found them satisfactory.

CLYDEBANK: *Transference of Electricity Order.*—The Finance Committee of the Town Council have had under consideration the question of the Clyde Valley Electrical Power Company transferring their Electricity Order to the Strathclyde Company. The clerk reported that the companies had agreed to all that the Council had asked. The Committee therefore agreed not to oppose the transfer.

DUNDEE: *Extension of Area.*—All the requirements in connection with the Electric Lighting Extension Order recently lodged by the Corporation with the Board of Trade have been complied with, intimation to this effect having been received. The purpose of the Order is to extend the area of supply so as to include the whole of the district annexed under the recent Local Government Provisional Order.

Brakes for the Electric Cars.—The Dundee Tramway Committee are taking every precaution in regard to the brake power on the cars, and on the 13th inst. they decided to equip six new cars now being built with pneumatic brakes at a cost of £65 for each car.

GLASGOW: *The Dalmuir-Dumbarton Tramway.*—Work on this tramway was commenced on the 20th inst., and it is expected that within a few months Glasgow people will be able to travel to Loch Lomond by car, a distance of 20 miles.

GRIMSBY: *The Electrical Undertaking.*—At a meeting of the Grimsby Corporation Electric Lighting Committee, held on the 20th inst., the Borough Electrical Engineer, Mr. W. A. Vignoles, reported that during the month, 215,951 units of current had been sold, an increase of 83,351 units upon the previous month's consumption. Mr. Vignoles suggested that the committee should adopt the standard wiring rules of the Institution of Electrical Engineers. Accidents had happened under the existing lighting rules, and they needed revision. The institute's standard rules precluded "shoddy" wiring. The committee decided to adopt the rules.

HANLEY: *Electricity Undertaking Costs.*—The working costs of this undertaking have varied little during the past four years, in spite of the greatly increased output. For 1903 it was £5,160; 1904, £5,685; 1905, £5,125; and for 1906, £5,131. The gross expenditure, including management, &c., was £74,024; added to this were interest payments of £25,528, and repayments of loans equalling £22,680, and the total receipts had equalled £125,000, in the twelve years the works had been in operation. The profits are roughly £8,600, and losses £3,600, leaving a surplus of £5,000.

HASLINGDEN: *Electric Lighting Order.*—It was reported at the Haslingden Council meeting on January 16th that in response to representations made to them by the Council, the Board of Trade were prepared to extend the Electric Lighting Order held by the Corporation for a further period of twelve months.

HOLYHEAD: *Electric Lighting Undertaking.*—The accounts of the Holyhead Electricity Committee for the past year show that there is a profit of £376. The number of consumers has increased from 30 to 292 in the three years during which the works have been in existence.

HOUGHTON-LE-SPRING: *Breach of Mining Regulations.*—At Houghton-le-Spring on the 16th inst., a miner employed on an electric coal-cutting machine at the Lambton Pit Colliery, was charged with a breach of the mining regulations. It was stated that owing to the defendant allowing the cable to get between the wall and the cutter some of the insulating material was rubbed off, the cable fused, and the machine fired. The defendant received a shock, and was fortunate in not being killed. He was fined 10s. and costs.

HUDDERSFIELD: *Electric Tramway Receipts.*—The report of the Tramways Committee showed that for the nine months ended December 31st, the total working expenses of the tramways amounted to £52,054, against £51,044 in the previous corresponding period. After allowing for interest on capital, redemption of debt, and depreciation, the net surplus was £5,536, against £2,900 in the preceding nine months.

HULL: *The Electricity Supply Breakdown.*—On January 14th a breakdown occurred at the Sculcoates Lane generating station, due to the failure and burn-out of the 2,200-volt armatures of three of the largest machines. This burn-out caused a cessation of the supply throughout the greater portion of the centre of the town from 4.20 p.m. to 4.50 p.m., but the district near the station was kept alight by the low-tension sets. One of the damaged armatures was totally destroyed, and will have to be rewound, and two others will in all probability require similar treatment. The Hull system is quite an uncommon one, being high-tension direct current, and is by far the largest undertaking of its kind at 2,200 volts in the United Kingdom, and the consequence has been that dynamos made for the Corporation have been largely experimental, and confined to a small number of manufacturers. The result of this is that the design of the machines at Sculcoates Lane embodies many features which preclude any likelihood of their continued successful running in the future. The Engineer regrets to have to say that he does not feel justified, either in the interests of the Corporation or himself, in accepting further responsibility in connection with them. He emphasises the fact that owing to the rapid way in which the undertaking is growing, the largely increased number of power users who are entirely dependent upon the Corporation system for a supply, and the very much greater usage which the plant now receives, the time has arrived when the Corporation must take into consideration the question of replacement of at any rate a portion of this defective part of the plant without delay. In dealing with the question of replacement, the Corporation is faced with the difficulty of finding any firms of repute who have had experience in the building of this class of machinery. The two latest machines in the station were built by the Lahmeyer Company, and have been running on full load for over 12 months and given every satisfaction. The Council has decided to purchase three more similar sets from that company, and these sets are to be installed before November next.

LARKHALL: *Fire at a Colliery.*—Early on the morning of January 15th a fire broke out in the power house of the Bitrkrigg Colliery, and the electric light plant, the engines for driving the coal-cutting machines and engine house, were entirely destroyed. The damage is estimated at £2,000.

LONDON: *London County Council.*—The L.C.C., on Tuesday, at the first meeting after the Christmas vacation, considered an application by Stepney Borough Council for sanction to borrow £42,150 for the equipment of a new generating station at Blyth's Wharf, Limehouse. The total estimated cost of providing the station, without allowing for extensions, is £66,565. The Finance Committee, reporting upon the application, stated that in the absence of a cheap supply in bulk, Stepney Borough Council could probably not do better than establish a generating station as proposed. Full particulars of the loan applied for had not been submitted, but sufficient information had been supplied to enable the committee to recommend that sanction be given to the borrowing of £22,000, on the understanding that the whole of the cost of new foundations, pipe, or cable connections, &c., be paid out of reserve fund and not out of the borrowed money.

Mr. McKINNON WOOD remarked that in consequence of the action of the County Council last year, the bulk supply scheme for London had not been carried through, and now, in this case, there was to be an expenditure of £66,000 on a generating station which no expert would say was an economical one.

Mr. HAYES FISHER said that so far as this particular case of Stepney was concerned, there was no evidence that if the County Council had acted otherwise than it did, the £66,000 would not have been expended.

Capt. HEMPHILL deplored the fact that the Council had done nothing towards securing a cheap supply of electricity for London. It was a pity they were allowing Borough Councils and private companies to fritter away money in dealing with this question in a piecemeal fashion.

Mr. GORDON, the representative of Stepney on the L.C.C., said they had come to the conclusion that they could not hope to obtain from outside sources a supply of electricity as cheaply as they could generate it for themselves, and so they

Digitized by Google

proposed to build a generating station which, he believed, would compare favourably with others in regard to equipment and up-to-date-ness.

The Finance Committee's recommendation was then agreed to.

Applications for loans for electricity purposes were also granted as follows:—Battersea, £2,154; Woolwich, £3,000.

The Highways Committee reported that as Greenwich Borough Council had refused their consent to the construction of a junction line of tramways between the electric conduit tramways in Deptford High Street and the tramways in South Street, Greenwich, the scheme, estimated to cost £87,100, must be abandoned.

The two chimneys at the second portion of the Greenwich generating station, which have only been built to a height of 204 ft. owing to questions raised as to the effect upon the Royal Observatory, are to be completed, but not heightened, at a cost of £2,275.

The Council decided to fix draught screens to 423 roof-covered cars, at a cost of £10 per car. Fifty cars will be dealt with during the current financial year, and the remainder during 1908-9.

The Highways Committee reported as to negotiations which had taken place between the Metropolitan Electric Tramways, Limited, the Board of Trade, and the Committee, with reference to the proposed purchase by the L.C.C. of the Harrow Road tramways. Representations were made by the company to the effect that inconvenience would arise from the dual ownership of the tramway, and the Board of Trade intimated that before approving the purchase they would require to be satisfied that public interests would not suffer. In reply, the assurance was given that the Council would be prepared to come to any reasonable agreement for dealing with the matter, either by the Council working the tramways itself with mutual running powers, or by leasing the lines to the outside authority. The Board of Trade eventually approved the service of notice of purchase. It was decided to enter into negotiations and take all necessary steps in connection with the arbitration (if any) with reference to the purchase.

Battersea: Electricity Station Accident, &c.—The Lighting Committee of the Borough Council report the receipt of a writ of summons on behalf of Messrs. Mather & Platt, Ltd., with reference to the spare armature supplied by them in connection with the steam generating plant at the central station, payment of which had been deferred owing to alleged non-compliance with the provisions of the contract. The Committee has given directions for the matter to be brought before the Law and Parliamentary Committee. It appears from the report made by the Board of Trade upon the preliminary inquiry with reference to the explosion from a stop valve at the central station on November 1st, during the time of inspection by the engineer of the National Boiler & General Insurance Co., Ltd., that the explosion was caused by water hammer action, brought about by opening the drain and stop valve when the horizontal steam pipe between No. 1 engine and the main range of pipes contained water subject to the steam pressure of the boilers. No person was injured as a result of the accident.

Reconstruction of the Tramways.—With reference to the coming electrification of the Lavender Hill tramline, the Finance Committee of the Battersea Borough Council reported that the London County Council would sanction street widenings, "subject to the Borough Council agreeing (1) to contribute one-third of the net cost of such widenings, (2) to exercise any compulsory powers it may possess for acquiring the necessary property, and (3), to appoint the County Council's officers to act in the matter on behalf of the Borough Council. The committee decided "That the three conditions mentioned in the letter be agreed to; all details as to the material to be used in paving the roadways and as to levels, cost of altering same, and setting back kerbs, &c., to be a matter for subsequent arrangement with the London County Council."

Islington: The Exchange of Lighting Areas.—The sum paid to the County of London Electricity Supply Co., in respect of the exchange of electric lighting areas between Finsbury and Islington, for goodwill of consumers transferred, viz., £1,076, is to be charged to the electricity reserve fund.

Poplar: Public Lighting.—At a meeting of the Borough Council it was decided to substitute metallic filament lamps, for the existing carbon lamps for the lighting in the side streets. The cost of the lamps will be £416 13s. 4d. per annum, but they will save £228 10s. in current, and give 40 c.p. more per lamp column.

Southwark: Electricity Undertaking.—At the next meeting of the Southwark Borough Council, a report of the district auditor on the municipal electric light undertaking will be submitted, according to which the undertaking, which in the past has been a loss to the ratepayers, last year showed a profit of £473. Now the council is "free wiring" consumers' premises, and thereby anticipates a great increase in the supply.

The London Electric Supply Co.'s Offer.—The Electricity Committee reported on Tuesday having considered a letter from the London Electric Supply Corporation, Ltd., offering to supply energy in bulk, and urging that the principal advantage of such an arrangement would be to relieve the Council of the necessity of raising further capital in respect of the electric supply undertaking, while the price at which the supply would be given by the company would enable the Council to distribute it at a profit. The company's letter further stated that should the Council not see their way to take a bulk supply, the company would be willing to take over the lighting of those streets in the borough which are at present lighted by electricity and also to light such other streets as are at present lighted by other means, and offering to quote terms in respect of either or both proposals. The Electrical Engineer was directed by the Committee to report upon the desirability or feasibility of linking the undertaking up with some other company or undertaking (assuming the Council to have the power to do so, and the company to have power to make the supply) with a view to making provision to meet emergencies or breakdowns. From the report presented to the committee on the matter it appears that the expense of carrying out such a scheme would necessitate the expenditure of a considerable sum which would far out-weigh any advantage likely to accrue by adopting the proposal. The assumption that by accepting the company's proposals the Council would be relieved of the necessity of raising further capital in working the undertaking was not borne out by the Engineer's report, which states that the process of linking up with another supply authority would cost in transforming apparatus—including transformers, motors, generators, switchgear, &c.—not less than £3,000, and might exceed that sum by £500—neither would it enable the Council to evade further capital expenditure if they propose to continue the development of the undertaking. Under all the circumstances the Committee failed to see that any advantage would accrue to the undertaking by taking a supply of current in bulk or otherwise from an outside source, and they had, therefore, decided that no action be taken on the letter.

MACCLESFIELD: *The Provisional Order.*—The Council are applying to the Board of Trade for a Provisional Order under the Lighting Acts of 1882 and 1888, for the following purposes: (1) To amend Section 6 of the Macclesfield Electric Lighting Order, 1901, and the provisions of the Electric Lighting (Clauses) Act, 1899, referred to in that section by extending the times within which distributing mains are to be laid down. (2) To authorise the Corporation to transfer and assign all or any of the powers, &c., of the Corporation, under the Order of 1901, to the Macclesfield Electric Lighting and Power Company, Ltd., or any company or person to be named in the intended Order. (3) To divest the Corporation of any legal powers imposed upon them by the Order of 1901.

MANCHESTER: *Tramways Parcel Delivery.*—At a meeting of the Manchester Tramways Committee, held on the 14th inst., it was stated that the result of the working of the parcels delivery system showed a profit of £1,084. The receipts were £3,670, and the expenditure was £2,586.

MANITOBA: *Government Telephones.*—The Manitoba Government took over the Bell system of telephones on the 15th inst. A reduction in the rates under the public ownership is promised in six months' time.

NORWICH: *The Great Eastern Railway Bill.*—The Law and Parliamentary Committee are raising a petition against the Great Eastern Railway (General Powers) Bill. It is proposed in the Bill that the company shall supply electricity to Parkeston, and to tenants of the company, and occupiers of premises connected by sidings with the railway undertakings of the company, or to any local or sanitary authority, or company authorised to supply electrical energy. The Corporation are taking this step to protect their own interests.

PERTH: *The Jeanfield Tramway Extension.*—At a meeting of the Perth Town Council held on Monday the 13th inst., it was decided, after a long discussion, to extend their tramway system to the Jeanfield district.

PONTYPRIDD: *Electricity Undertaking Progress.*—At a meeting of the Pontypridd District Council Electricity Committee, it was reported that the receipts for December amounted to £719 18s., as compared with £561 in the corresponding month of last year, while the tramway receipts totalled £845, as against £671 for the corresponding month last year. The Christmas traffic on the tramways for the week showed an increase of £71 10s. over the same week of the previous year.

READING: *Tramways Receipts.*—At a meeting of the Tramways Committee, held on January 2nd, the tramways manager reported that the receipts during the fourteen days from Monday, December 16th, to Sunday, December 29th, inclusive, constituted a record, amounting to £1,355. The previous highest takings for the same period were £1,309 in 1904. The traffic returns for the nine months ending December 25th from April 1st, 1907, were £24,368, against £25,149 17s. in 1906.

UXBRIDGE: *Transfer of Lighting Orders.*—The Uxbridge and District Electric Supply Co., Ltd., are applying to the Board of Trade for approval to transfer a portion of their supply area to the Metropolitan Electric Supply Co., Ltd., situated in the Urban District of Greenford. A plan of the area has been deposited at the Board of Trade offices. A copy of the proposed deed of transfer and plan have been deposited at the office of Messrs. H. C. Cleaver, Ltd., Tudor Works, Park Royal, Willesden, where copies can be obtained. Objections to the proposed transfer are to be made to the Assistant Secretary, Harbour Department, Board of Trade, 7 Whitehall Gardens, before the 17th day of February, 1908.

TENDERS INVITED AND PROSPECTIVE BUSINESS

AUSTRIA-HUNGARY.—Tenders are invited for the supply of electric lighting materials for the railway works at Pilsen. Tenders should be sent to the K. K. Staatsbahndirektion at Pilsen before January 30th.

AUSTRALIAN COMMONWEALTH.—The representative of the Commonwealth in London (Captain R. Muirhead Collins, C.M.G.), notifies that he has received tender forms, specifications, &c., in connection with the supply and delivery of thirty-three switchboards for private branch exchanges for common battery working, for which tenders will be received at the office of the Deputy Postmaster-General, Sydney, up to 2.00 p.m. on March 4th. Specifications, tender forms, &c., may be obtained at the Commonwealth Offices in London, 72 Victoria Street, S.W., where also preliminary deposits on tenders may be paid. Copies of the specification and conditions may be inspected at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

BANGOR.—A Local Government Board inquiry has been held into the application by the Corporation for sanction to borrow £1,000 for electric lighting purposes.

BEXHILL.—In connection with the application of the Urban District Council to the Local Government Board for sanction to borrow £5,800 for extensions to the electrical plant, the following amended estimate has been prepared:—Dynamo and engine: Contract, £2,899; foundation, &c., £120. Boiler: Contract, £1,560; foundations, &c., £336; pipe work, £450; switchboard, £250. Store: Contract, £215; fixtures, &c., £ 5. Total, £5,855. The application is therefore to be made for the increased sum.

BRISTOL.—The Docks Committee invite tenders for the supply, delivery and erection, and maintenance for 12 months after they have been in use, of electric cables for the supply to Avonmouth Docks. The tenders are also to include the construction, delivery, erecting in place, fitting, completion, and testing and the maintenance for 12 months after they shall have been taken into use of the electric lighting installations, complete in all details, for the various buildings, railway yard, wharves, &c., at the Royal Edward Dock, now in course of construction at Avonmouth. Specifications, &c., from the Secretary of the Docks Committee (fee £5, returnable), and tenders to 19 Queen Square, Bristol, by February 17th.

CHELTENHAM.—Tenders are invited for the supply of electric light fittings, among other stores, for the year ending March 31st, 1909. Particulars from the Borough Surveyor, to whom tenders by January 31st.

CHISLEHURST.—The Chislehurst Electricity Supply Co. is to erect a new sub-station at Lower Camden at a cost of £3,000.

CROYDON.—The Corporation has decided to install coal-conveying plant in the generating station at an estimated cost of £2,525, made up as follows:—Coal bunkers, £980; conveyer, £850; automatic measures, £195; building, £500.

EDINBURGH.—Tenders are invited for an extension switchboard panel. Specifications, &c. (fee, two guineas, returnable), from Sir Alex. B. W. Kennedy, the consulting engineer to the Corporation, 17 Victoria Street, London, S.W., and tenders to the Town Clerk by February 10th. (See an advertisement this week.)

ESSEX COUNTY COUNCIL.—A Local Government Board inquiry was commenced last week at Colchester into an application by the Essex County Council to borrow £289,276 for the purposes of a new county asylum. Of this amount £4,300 is required for electrical generating plant.

ILFORD.—The Electricity and Lighting Committee brought up at the last meeting of the District Council a report recommending the extension of the plant at the generating station at a total cost (including buildings) of £27,000. There was also a recommendation that current be supplied for power purposes at the rate of 1d. per unit to consumers of over 20,000 units per quarter. The chairman of the Committee explained that the business was extending, and it would be necessary to have the extension ready by next autumn. During December 20 new accounts were opened, and in the previous month 35. Up to date they had 3,000 consumers in Ilford. The time was coming, he hoped, when they would be able to make a universal charge of 1d. per unit for power and heating. The chairman of the committee pointed out that although the generation cost was 0·99d. per unit, the output included current for both power and lighting: for the latter they got 3½d. per unit. They could, therefore, afford to take a lower charge for power supplied as a day load. In reply to further remarks the chairman said that the proposed extension was not intended to meet the case of any prospective new consumer, but to satisfy the demands of their present lighting consumers. The committee's recommendations were adopted.

ITALY.—The December *Bulletin* of the French Chamber of Commerce reports that the committee elected for the construction of railways across the Dolomite Alps have finished the preliminary work, and applications for authorising these lines have already been made to the Government. A company is being formed for the construction and working of the new system. The lines to be constructed are three: the first, from Bribano to Agordo; the second, connecting the Cadore line with Cortina di Ampezzo, with a branch line to Auronzo; the third, from Feltre to Primolano. The three lines will have a total length of more than 100 kilometres, and will be of narrow gauge. It is proposed to instal hydraulic works to provide the power for electric traction. It is stated further that the Italian Government have assigned a credit of 70 million lire for electric traction on various lines having steep gradients and long tunnels, and that a concession has been granted to a company composed of French, Belgian, and Italian capitalists for the exploitation of an electric railway between Rome and Naples.

The *Bollettino delle Finanze* announces that "Il Consiglio d'amministrazione delle Ferrovie has authorised the sum of 1,137,000 lire (about £45,480), to be expended on the conversion to electric traction of the branch railway line from Savona to S. Giuseppe, and also for the installation of a steam power station for the production of the electric current.

LEEDS.—Tenders are invited by the Electric Lighting Committee for steam, exhaust, overflow, and other pipes, valves, &c., in connection with a steam turbo-generator of 3,000 kw. capacity. Particulars from H. Dickinson, manager, the Whitehall Road, Leeds (fee, two guineas, returnable), and tenders to the Town Clerk by February 10th.

LONDON: *London County Council.*—Tenders are invited for the road-work and platelaying in connection with reconstruction for electric traction on the underground conduit system of the horse tramways in Caledonian Road and Seven Sisters Road. The total length is 5¼ miles single track. Contractors will be required to use the track rails and their fastenings, the slot rails and the conduit rails, and the special work for the various junctions and cross-overs, which will be supplied by the Council under other contracts, but all the remaining metal work and other material are to be included in the tender. Full particulars from the Chief Engineer at the County Hall, Spring Gardens (fee £5, returnable). Tenders to the Clerk by January 28th.

The Council also invites tenders for (*a*) the manufacture, delivery, and laying of about five miles of low-tension, lead-covered electric cable, and about two miles of telephone cables, &c.; and (*b*) the laying of stoneware cable ducts, building manholes, repaving, &c., for the reconstruction for electric traction of the Council's tramways in Caledonian Road and Seven Sisters Road. Tenders to the Clerk by February 4th (See an advertisement this week.)

NEWPORT.—The sanction of the Local Government Board has been received to the borrowing of £28,000 by the Corporation for the purposes of the Electricity Works.

NORTH EASTERN RAILWAY CO.—The directors of the North Eastern Railway Co. invite tenders for the erection of an electrical sub-station at West Hartlepool. Plans and specification may be seen, and quantities and further information obtained upon application to Mr. William Bell, the Company's architect, at York. Tenders to the Secretary at York not later than Monday, January 27th.

NORWAY.—It is stated that an underground electric tramway is to be constructed at a cost of £75,000.

RUSSIA.—The "Moniteur des Intérêts Matériels" (Brussels) reports that an agreement has been concluded between the tramway company and the Municipality of Odessa, by which the tramway system is to be extended from 80 to 140 kilometres, the company to be allowed three years (from the date when Government authorisation is received), to complete the system and to instal electric traction.

STRETFORD.—A Local Government Board enquiry was held last week into the application by the Urban District Council for sanction to borrow £42,718 for the purpose of the electrical undertaking. It was stated in evidence that the original scheme in 1903 was based upon an estimated demand of 400,000 units per annum, but that the demand of the first year was more than double this, and already extra plant has had to be put down, the cost of which is included in the sum for which sanction is now being sought. Of the amount for which sanction is being sought a sum of £36,990 is needed for structural alterations and new plant, the remainder being required to meet the excess expenditure over loans already sanctioned.

TAUNTON.—Application is to be made to the Local Government Board for sanction to borrow £2,000, which, it is estimated, will cover the next three years' estimate for the supply of meters and cables.

WEST HAM.—Tenders are invited for the supply of engine-room stores, rubber-cored cable electric wiring materials and accessories, and chemicals. Particulars from the Borough Electrical Engineer's office, 84 Romford Road, Stratford, E. Tenders by February 6th.

WIMBLEDON.—The Corporation invite tenders for the supply and erection of the undermentioned plant at their electricity works, and are prepared to accept tenders subject to the sanction of the Local Government Board being obtained for the necessary loan:—(*a*) A 1,000 kw. turbo-alternator, with condensing plant; (*b*) two water-tube boilers, economisers, pipe-work, and feed pump; (*c*) high-tension main switchboard

Digitized by Google

and switchboard gallery. Forms of specification and tender, with the general conditions, may be obtained from Mr. H. Tomlinson-Lee, the Borough Electrical Engineer, Electricity Works, Durnsford Road, Wimbledon (fee £1 each specification, returnable), and tenders to the Town Clerk by February 18th.

WOOLACOMBE.—The Council is considering whether it shall instal an electric lighting plant.

YARMOUTH.—Tenders are invited for the supply, delivery, and erection of a 400 kw. continuous-current traction generator. Particulars and forms of tender from the Borough Electrical Engineer, 20 King Street, Great Yarmouth (fee £1 1s., returnable), to whom tenders by February 1st.

TENDERS RECEIVED AND ACCEPTED

ADMIRALTY.—Messrs. Cowans, Ltd., have received an order for switchboards for H.M. battleships *Minotaur* and *Shannon*, and also for the Gibraltar Dockyard.

CROYDON.—The Corporation has placed an order with the British Electric Transformer Co., at £211, for two 100-kw. transformers.

BELFAST.—At the bi-monthly meeting of the Belfast Harbour Commissioners, on Tuesday, it was stated that nine tenders had been received for the construction of the new harbour tramway, and the engineer and electrical engineer of the Trust had recommended the tender of Messrs. Dick, Kerr & Co., Ltd., subject to certain modifications

FRANCO-BRITISH EXHIBITION.—Seven switchboards are being supplied by Messrs. Cowans, Ltd., in connection with the lighting of the Franco-British Exhibition, including Andrews' patent discriminating devices.

HULL.—The Corporation have confirmed a recommendation of the Electric Lighting Committee to purchase three Lahmeyer continuous current generators.

INDIA.—Messrs. James Gordon and Co. are supplying three of their patent Samson balanced gate turbines in connection with the Mulakand water power scheme in India.

LLANDUDNO.—The Urban District Council has accepted the tender of the Tudor Accumulator Co., at £1,741 for additional plant in connection with the light railway.

LONDON: *London County Council.*—The L.C.C. has accepted the following tenders for the supply of requisites in the tramway department:—Bullers, Ltd., 2,000 track insulators, at 3s. 5½d. each; Callender's Cable and Construction Co., Ltd., two miles of jumper cable, £800. The following tenders have been received for the supply, delivery, and erection of a car-traverser for the central repair depot:—Appleby's, Ltd. (accepted), £513 10s.; Heenan & Froude, Ltd., Worcester, £580. Permission to sublet portions of the work has been given as under—Supply of steel castings, Wm. Beardmore & Co., Ltd.; supply of steel plates, bars, angles, &c., Frodingham Iron and Steel Co., Ltd.; axles, wheel centres, and tyres, Hadfield's Steel Foundry Co., Ltd.

Battersea.—The Borough Council has accepted the tender of Callender's Cable and Construction Co., Ltd., for the supply of cables, &c. (based upon 25 tons of copper at the rate of £63 per ton) for one year, the company undertaking to maintain the whole of the cables supplied by them for a further period of twelve months.

Hammersmith.—A repeat order has been placed with Messrs. Cowans by the Borough Council, for sub-station switchgear, including Andrews' reverse current relays.

Islington.—The Borough Council has accepted the tender, at £548, of Daniel Adamson & Co. for repairs to an engine, steam pipes, and foundations at the generating station.

Westminster.—The City Council has accepted the tender of Messrs. Speedy, Eynon & Co. to maintain the electric light installation at Caxton Hall for three years at £35 for the first year and £30 per annum for the two succeeding years. The reason for the larger sum for the first twelve months is that the existing lamps have been in use for practically two seasons and now require replacing throughout, needing 400 lamps at once. It is almost certain that in addition at least another 100 lamps will be required before next Christmas if the lamps are to be run to the best advantage as regards current consumption.

LOWESTOFT.—The Corporation have accepted the tender of Messrs. Siemens Bros. and Co., Ltd., for the supply of a 45-h.p. electric locomotive at £472 for use on the proposed new coal siding. The tender of the Electrical Co. has also been accepted for the supply of meters during the coming year.

METROPOLITAN ASYLUMS BOARD. The following tenders were received for the installation of electric lighting at the Mead Ambulance Station: T. Potter & Sons, Ltd., £139 (accepted); Speedy, Eynon & Co., £143; C. Pullan, £145; A. V. Gifkins & Co., £149; Smeeton & Page, £178 2s. 6d.; The Electrical Co., Ltd., £180; Dargue, Griffiths & Co., Ltd., £183; H. J. Cash & Co., Ltd., £185; Edmundson's Electricity Corporation, Ltd., £186 10s.; G. Weston & Sons, £189; A. Plocknell, £192; J. Wilson, £192; C. Cooper & Co., £210 10s.; Jenkins & Cawte, £229 15s.; Fulham Electric Supply Co., £253; W. G. Cannon & Sons, Ltd., £266 16s. 11d.; The Kevan Electric Co., Ltd., £335.

SWINDON.—The Electricity and Tramways Committee recommend that the tender of Messrs. Thomas Parker, Ltd., of Wolverhampton, for a variable speed motor and regulator for the boiler-house, be accepted at £45 10s., and that the tender of Messrs. W. and T. Avery, of Birmingham, for a weighing machine with automatic tape register at £30, also be accepted.

THE MIRRLEES WATSON CO.—The Mirrlees Watson Co., Ltd., Glasgow, have recently received orders for a number of condensing plants, amongst which are the following:—John H. Wilson & Co., Birkenhead; National Electric Construction Co. for Rhondda Trams; Huddersfield Corporation, elevated counter current jet plant, dealing with 120,000 lb. steam per hour, 28⅝ in. vacuum, with cooling tower water; John Brown & Co., Ltd., Sheffield, elevated jet condensing plant. Repeat orders have also been received from the British Thomson-Houston Co., for Rangoon, and the City Road station of the County of London Electric Supply Co., and from the Trafford Park Electric Supply Co.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net c.i.f. port of arrival quoted on Tuesday night was £65 to £65 10s. This is no change in the price last week.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The first meeting of the creditors in the bankruptcy of G. K. Spivey, electrical engineer, 54 Pinderfields Road, Wakefield, was held last week at the Official Receiver's office, 6 Bond Terrace, Wakefield, Mr. J. Eickersteth Ottley presiding. No creditors were present or represented, therefore no resolutions were passed, and the estate remains in the hands of the Official Receiver.

A meeting of Messrs. Witting, Eborall & Co. will be held at 49 Cannon Street, London, E.C., on February 15th at 12 noon, to hear the liquidator's account of the winding-up. This firm, it may be remembered, went into voluntary liquidation when Mr. A. C. Eborall became the representative here of Messrs. Brown, Boveri & Co.

A petition for the winding-up of Messrs. D. Santoni & Co. (1905), Ltd., will be heard on Tuesday, January 28th, at the Royal Courts of Justice, Strand, London.

Reason Electrolytic Meter.—The Board of Trade has approved a pattern of electrolytic meter made by the Reason Manufacturing Co., Ltd., and known as Wright's electrolytic meter, Hadfield's solution, and also the method of fixing same.

The Lots Road Smoke Nuisance Prosecution.—In connection with the unsuccessful summonses taken out by the Chelsea Borough Council against the Underground Electric Railways Co., of London, Ltd., for permitting the emission of black smoke from their generating station at Chelsea (ELECTRICAL ENGINEERING, Vol. II., pp. 711 and 770), a suggestion was made that the London County Council should contribute to the costs. This was in consequence of the pressure brought to bear by the London County Council upon the Borough Council to prosecute, the latter being threatened with treatment as a defaulting authority under the Public Health Act unless proceedings against the company were taken. The London County Council now state that they have no authority to make any contribution towards the costs in question.

Electrical Exhibition at Acton.—An Electrical Exhibition promoted by the Urban District Council of Acton in the interests of their supply undertaking, was opened last Monday. Councillor R. Dunsmore, in introducing the Mayor of Hammersmith, who kindly consented to formally open the exhibition in the absence of Mr. Herbert Nield, M.P., explained the various uses to which electricity could be put in the home and the workshop, and recommended those present to inspect carefully the various appliances for lighting, heating, and power, which would be found on the stalls. The Mayor briefly replied, and mentioned that the success of the undertaking depended largely on the number of patrons, and he trusted that this large gathering would mean a considerable number of new consumers. Councillor F. A. Baldwin passed a vote of thanks to the Mayor, which was seconded by Councillor R. Poulton, and gave a short outline of the history of the undertaking. The principal exhibitors are given below:—Mr. G. C. Berry, of Acton, Edison lamps and B.T.H. cooking appliances; Messrs. Robert King & Co., Victoria Street, S.W., numerous specialities for which they are agents; Messrs. Pooley & Austin, Victoria Street, S.W., "Spagnoletti" instruments and switches, "Mawdsley" motors, and two Engineering Instruments Co.'s switchboards, which had just been manufactured for the Acton District Council; Siemens Bros.' Dynamo Works, Ltd., tantalum lamps and motors; Dowsing Radiant Heat Co., Ltd., their well-known heating appliances and electro-medical apparatus, also samples of the new 60 c.p. zirconium metallic-filament lamps being used direct on a 230-volt circuit; Messrs. J. Poore & Son, various specialities of the General Electric Co., and demonstrations of the processes of the manufacture of the Robertson lamp; Messrs. Waygood & Co., Ltd., model of their well-known automatic electric lift; the Sunbeam Lamp Co., Ltd., had on view a case of samples of their numerous styles of incandescent lamps. The exhibition will be open every day until the 25th inst., and various entertainments are to be given during the course of the week

Digitized by Google

MISCELLANEOUS CITY NOTES

BRITISH ALUMINIUM CO.—An extraordinary general meeting will be held to-day at Winchester House, Old Broad Street, London, to consider a resolution for dividing the £10 conversion shares created in 1906, into two shares of £5 each, viz., a 7 per cent. preference share and an ordinary share ranking *pari passu* with the existing shares.

DIRECT UNITED STATES CABLE CO.—The revenue for the half-year to December 31st was £58,268, compared with £60,379 for the corresponding period of the previous year. Working and other expenses were £25,103, leaving a balance of £33,165, exclusive of £2,515 brought in. Two interim dividends of 4s. each absorb £24,284, and, after setting aside £5,000 to the reserve fund a balance of £6,396 is carried forward.

HARPER ELECTRIC PIANO CO.—A dividend of 10 per cent. on the preference shares for the half-year ended December 31st, 1907, has been declared.

MACCLESFIELD AND DISTRICT TRAMWAYS CO.—A special general meeting will be held at the offices of Messrs. Kidsons, Taylor, and Everatt, 1 Booth Street, Manchester, on February 3rd, at 4 p.m., for the approval of the company's Bill deposited in Parliament. This proposes the abandonment of the tramways already authorised.

METROPOLITAN RAILWAY CO.—A dividend of ½ per cent. per annum has been declared upon the ordinary stock for the half-year ended December 31st, 1907, and the sum of £5,500 is carried forward. The dividend on the surplus lands stock is at the rate of 2¾ per cent. per annum, carrying forward £900.

MONTREAL LIGHT, HEAT AND POWER.—A dividend of 1½ per cent., or at the rate of 6 per cent. per annum, for the quarter ending January 31st, has been declared.

P.P.K. CEYLON RUBBER ESTATES.—The directors have announced a dividend at the rate of 2½ per cent. per annum for the year ended December 31st, 1907.

THE UNDERGROUND ELECTRIC RAILWAYS COMPANY OF LONDON.—According to the *Financial Times*, a meeting of the Dutch holders of profit sharing notes in the Underground Electric Railways Company of London was held at Amsterdam on the 14th inst. The report of the meeting, sent by the Amsterdam correspondent of the *Frankfurter Zeitung*, states that the meeting, which was convened by the Committee of the Stock Exchange, appointed a committee to examine any proposals for reorganisation. It was announced that out of the total of £7,000,000 in outstanding notes £1,500,000 is in the hands of Dutch holders. These comprise £600,000 in administration certificates, and £900,000 in original notes. During the discussion attention was drawn to the declaration that the amount which had been expended by Messrs. Speyer and Co. for the payment of the December coupons forms a debt of the company.

PERSONAL.—Mr. F. M. Saxelby, head of mathematics at the Technical College, Belfast, has been appointed to a similar position at the Battersea Polytechnic. Previous to his appointment at Belfast, Mr. Saxelby was head of the Mathematics Department at the Royal Technical Institute, Salford.

Moscow Tramways.—In connection with the contract which has been given to a British syndicate for the conversion of the Moscow tramways to electric traction, a Reuter telegram from Moscow on Monday states that the guarantee of £10,000 has been deposited.

Telegraph Traffic.—The Trinidad-Demerara Cable noted in our last issue as being broken, was restored to working order on the 17th instant. At last the cable between Brest and Dakar has also been repaired. This cable has been inoperative since July 22nd, 1907, but traffic was resumed on the 17th instant. The Singaradja-Amperan cable and the Fao route were restored on the same day. It has become necessary to undertake repairs on the cable between Teneriffe and St. Louis, Senegal, and traffic has in consequence to be sent *viâ* Madeira. The Lagos-Kotonon cable, which was down on December 4th, was repaired on the 18th inst. An earthquake at Gonaives is reported to have been the cause of the cutting off of this town from communication with the outside world. Official advices from the Haitien Government state that all offices of the land line system are at present closed as far as international traffic is concerned. The interruption, however, may possibly be due to a revolution. Telegrams may still be accepted for stations at which submarine cables land, viz., Cape Haitien, Mole St. Nicholas, and Port-au-Prince, and from these towns they will be sent by post to places in the interior, but only at sender's risk. Owing to the break of the Teneriffe-St. Louis cable, messages for West Africa and South America cannot be accepted for transmission *via* Teneriffe, but should be sent *via* France and Dakar. Telegraph offices have been opened at Greatham, Hants, and at Melsonby, Yorks. According to information the proposal to establish a wireless system between British Guiana and Trinidad, which was passed by the former colony, has been rejected by the latter.

THE UNION ELECTRIC CO.'S NEW WORKS

The Union Electric Company held a conference of all their agents at the new works on Thursday last, and afterwards held a reception, at which, by their invitation, we were able to be present. This company recently moved from their old premises in Queen Victoria Street to Park Street, Southwark, and after only a few months' tenure there, the business has increased to such an extent that they have again been compelled to take additional works. At these new works a complete installation of machinery has been put down for the manufacture of switchboards, arc lamps, &c., which are manufactured on the premises. The company had on view some of their more recent manufactures, which made a very interesting display. Among these their well-known "Excello" arc lamp, in all its latest improvements, was exhibited, the most recent being the improved sleeve, which by means of its construction allows all gases from the interior of the globe to be led directly to the atmosphere, and at the same time it does not allow cold air to gain access to the burning area. This entirely prevents the deposit which used to accumulate on the globes. Another new lamp is the Snowball type of lamp, which has a full-moon-like effect, which renders them useful for picture galleries, &c. One of the special features of this lamp is the elimination of practically all the violet rays, thus giving a silvery white illumination over the whole surface of the globe. The Koh-i-noor lamp is one of their latest productions, and is a remarkable miniature arc lamp, which has great economy in current, maintenance, and carbon consumption, coupled with long burning hours. The lamp gives a mean candle-power of 700, and takes 6 mm. carbon, with a consumption of ½ unit per hour, and 30 hours' burning capacity; the general design of the lamp is extremely artistic, and suitable for decorative schemes. The size of the lamp is only 21½ in. long, with a 7-in. globe. The firm also make a speciality of inverted arc lighting, and reflection from the ceiling, and in most of their offices and works this method has been employed. In some cases, where it is necessary that the source of light shall be concealed, a metallic reflector is placed beneath the arc, but in other cases opal or translucent glass is employed, which allows some of the rays from the arc to pass through. This method of lighting gives an even distribution of light, resembling daylight. The company have installed a testing department, where every lamp is tested, and its certificate of the test is attached, and the lamp is then placed in a packing case and sealed, and is then placed in the stores ready for sale, and the case is not opened again on the works. The company has vast stores on the ground and basement floors of the building, and separate departments for switchboard stores. The company also exhibited several types of their various switchgear, traction type overload cut-outs, reverse current cut-outs, and all kinds of alternating current breakers, and a quick-break main switch for currents up to 300 amperes. Several specimens of the company's volt and ampere meters were shown, and also several testing sets, and the Hanby watt hour meter for single and polyphase currents. The company are now manufacturing, on the premises, high-tension switchgear of all kinds, and oil brake switches, which are either double or triple pole. There are also remote control H.T. oil break switches, which are controlled by H.T. relays, time relays, or similar devices by means of direct current at low voltages. On Thursday evening the company gave a dinner at the Café Royal, Regent Street, W., to all their provincial agents and many guests; about 140 people assembled. After an excellent repast a smoking concert was held, which was thoroughly enjoyed by everyone.

The Board of Trade and the Electric Lighting Acts.—The Board of Trade recently received a letter from the Town Council of Hastings urging the desirability of municipal authorities being empowered to wire premises for consumers, and to supply fittings. The Town Council stated that they were adverse to incurring the large expense involved in promoting a private Bill with the express object of obtaining the powers referred to, and they asked whether the Board contemplated introducing a measure for extending the Electric Lighting Acts so as to confer, *inter alia*, upon all local authorities who own electricity undertakings the powers in question. The Board of Trade has now replied to the effect that they hope to introduce a Bill next session to amend the Electric Lighting Acts, and in the event of their doing so the matter to which attention had been drawn by the Hastings Town Council would receive consideration.

SUMMARY

A SERIOUS mains explosion occurred on Sunday night on the Westminster network, the result of which was two broken windows in Mr. Leopold de Rothschild's house in Hamilton Place. A short circuit occurred in a bitumen main crossing the road, and an explosive mixture of bitumen gas and air penetrated through a service box to a cellar in the area of the house. (Page 150.)

AN article by Mr. E. L. HILL reviews the advantages of electrical driving for textile mills, and deals with the question whether preference should be given to group drive or individual drive in different cases. (Page 151.)

AMONG the further local authorities in London and Greater London who will oppose the Electric Power Supply Bills are Woolwich, Paddington, Hendon, Richmond, Stepney, Lewisham, and the Middlesex County Council. The Bills will start in the House of Lords. (Page 152.)

THE commissioners of the Board of Trade appointed to inquire into the boiler explosion at the Greenwich station of the South Metropolitan Electric Light & Power Co. in December, 1906, have given judgment to the effect that no blame attaches to the firm who supplied the boilerplate, while considerable responsibility rests with the boiler-makers. The chief and resident engineers to the station are also held responsible in a minor degree. The commissioners do not in any way attribute the explosion to conditions attendant upon the use of thermal storage. (Page 153.)

AN action was commenced on Tuesday last week in the King's Bench Division, by two Italian electrical engineers against the executors of the late Sir John Pender, Bart., for breach of contract made in December, 1889, in connection with certain water-power rights and concessions for the purpose of supplying electrical energy to the City of Rome. The hearing lasted until Monday, when it was stated that terms had been arranged between the parties. (Page 154.)

THE action by the Rev. EDWARD HEATH, Vicar of St. Mary and St. Mary Magdalene Church, Brighton, brought against the Corporation for alleged nuisance from vibration caused by the electrical machinery at the North Road sub-station, was continued in the Chancery Division this week. Evidence has been given on behalf of the Corporation by Mr. JAMES SWINBURNE, F.R.S., Prof. C. V. BOYS, F.R.S., and Mr. ARTHUR WRIGHT. The hearing has been adjourned until to-day, when it is expected that judgment will be delivered. (Page 154.)

DR. R. GOLDSCHMIDT read a Paper last Thursday at the Institution of Electrical Engineers, the object of which was to provide in a convenient form data of what

Digitized by Google

may be regarded as the standard performance of electrical machinery. Continuous-current machines, rotary converters, alternators, induction motors, and single-phase commutator motors were dealt with, and numerous curves of efficiencies and other properties of such machines over a large range of sizes were given. The discussion was opened by Prof. SILVANUS THOMPSON, who drew some distinctions between the constants in the formulæ based on first principles and empirical results, and discussed the constancy of the value of the ratio between the armature load and the flux in machines. Mr. MACFARLANE considered such a fixed ratio inadmissible, and quoted examples to show that the author's flux curve did not represent the most economical conditions, and Mr. V. A. FYNN complained that the section on single-phase machines was not sufficiently specific. Mr. H. BURGE also spoke, and Col. CROMPTON questioned the possibility of standardisation of such matters. Dr. GOLDSCHMIDT, in his reply, pointed out that his results represented general averages, and were not based on particular designs. (Page 155.)

THE electrical winding plant, which the Priestman Collieries, Ltd., have installed in their Axwell Park Colliery, although of small size as compared with most main shaft winding engines, is a complete example of the Ilgner system with flywheel converter. (Page 163.)

DR. R. POHL'S Paper on recent developments in turbo-generators, read before the Institution of Electrical Engineers in London last November, was further discussed by the Leeds Local Section last week. One or two points which the author had not touched upon were suggested, and various means of minimising commutation troubles were discussed. Agreement was expressed with the author as to the impracticability of homopolar designs. (Page 166.)

IN the discussion in Glasgow on Mr. J. F. C. SNELL'S Paper on the cost of electrical power for industrial purposes, Mr. ROBERT ROBERTSON showed graphically the difference between the tabulated and actual figures quoted by Mr. Snell for independent plants, and thus brought out the difference very clearly. Mr. C. P. SPARKS criticised the estimated figure of £12 for transmission as far too low. Mr. LACKIE emphatically stated that Glasgow was not supplying power below cost price. He expressed surprise that Mr. Snell's costs for independent suction gas plant were higher than for steam plant, and gave some interesting figures for the diversity factors of various classes of load. Finally, he entirely disagreed with Mr. Snell in his view that the smaller towns should have been prevented from erecting their own generating stations, and said that even now Mr. Snell's suggested remedy would not prove beneficial, as the small towns would only call on the power company to supply their peak load in winter. Mr. J. ROBERTSON stated that the load factor of a shipyard was a bad one, but confirmed the figures quoted by Mr. Snell for such loads. The conclusions in the Paper, however, he regarded as too pessimistic; his own capital expenditure at Greenock was £43 per kw. Moreover, in his figures the author had not taken account of the capital already paid back. Mr. J. H. BOWDEN, in a communication received in London, says that his actual charge for power at Poplar in 1907 was 1·156d. per unit, whereas Mr. Snell actually credits him with charging the sum of 1·43d. per unit for something which ought to be charged at 1·686d., but which might be obtained elsewhere for 0·83d. Mr. W. B. ESSON expresses himself generally in agreement with Mr. Snell's figures as to the costs in private generating stations, and as to some of the present power charges in London being too low. (Page 167.)

PROF. KAPP, in his second lecture at the Royal Institution last Saturday on the "Electrification of Railways," considered briefly the chief characteristics of the forms of the continuous-current three-phase and single-phase systems now in use. (Page 169.)

A SHORT discussion followed the reading of Mr. BARLOW'S Paper on "The Heat Conductivity of Iron Stampings" before the Birmingham Local Section of the Institute of Electrical Engineers. The Paper was given at some length in our last issue. Some criticism of the mathematics was made by Dr. SUMPNER and others. But the importance of the experimental results was generally agreed upon. In the absence of the author, Prof. KAPP, at whose suggestion the experiments have been made, replied. (Page 170.)

AN original communication by Mr. P. H. POWELL, selected for publication in the Journal of the Institution of Electrical Engineers, describes some determinations of the air-gap correction coefficient for partly-closed slots of various proportions by the stream line method. (Page 171.)

THE manufacture of fine classes of iron and steel by electro-thermic methods is continually developing. For the actual refining of steel and iron, the electrical induction will probably be the furnace of the future. Under ELECTROCHEMISTRY AND ELECTROMETALLURGY we describe the new 5-ton Roechling-Rodenhauser furnace, which is being operated at the Roechling Iron Works at Voelklingen in Germany. Another very important development in the employment of electrical energy is in the manufacture of nitrogenous products from atmospheric nitrogen. We draw attention to a number of new works where the manufacture of calcium nitrate and cyanamide is or will be manufactured. (Page 172.)

A PAPER by D. F. COMSTOCK in the "Philosophical Magazine," of which an abstract is given under "ELECTRICAL SCIENCE," contains a mathematical investigation of the motion of a system of electric charges having an important bearing on the disintegration theory. In the Papers abstracted in the Continental section, CORBINO describes how to obtain undamped oscillations without a condenser, BECQUEREL develops some new aspects of his magneto-optic effect, RUNGE assigns a place to the new infra-red series of lines of the alkaline elements, and THULLIE confirms and develops Langevin's electron theory of magnetism. (Page 173.)

AMONG the specifications published to-day is one by W. P. HAMLYN describing an automatic circuit-breaker of the loose-handle type, which is actuated independently of the toggle catch. In the 1907 specifications the BRITISH THOMSON-HOUSTON CO. have one relating to direct-current transmission systems of the high-tension type, in which unipolar generators are connected in series for producing the voltage required, and a special means is provided for keeping the voltage steady. A new method of sealing the leading-in conductors of metallic filament lamps is patented by the same firm, who have also patented a new method of insulating composition for electric conductors. A specification by E. PEARCE and S. WALTON is for an improved method of regulation for inclined carbon lamps, designed to prevent over-feeding and sticking of the carbons. POULSEN has improved the method of periodically damping the oscillations in wireless signalling, and can regulate the vibrations of the circuits connected to the antenna. There are no patents of electrical interest expiring during the present week. (Page 173.)

THE Brentford Council are not opposing the L.C.C. Tramways Bill for the tramway across Kew Bridge. The Brighouse Town Council has decided to purchase electricity from the Yorkshire Power Company, and are building a sub-station. The Cardiff tramway track repairs ordered by the Board of Trade will cost £100,000. Sir Alex. Kennedy has advised the Dunfermline Town Council to sell its Provisional Order to the Fife Power Company. The North Metropolitan Electric Supply Co. are considering a scheme for the supply of power in bulk to the Finchley Council.

Digitized by Google

MESSRS. CROMPTON & Co. are seeking a provisional order to transfer the Hendon Electric Lighting Order to a company called the Hendon Electric Supply Co. The Stoke Newington Council propose to erect a generation station in connection with their destructor at an estimated cost of £3,700. The West Ham Corporation electricity accounts show some interesting figures, as also do those of Plymouth and Sheffield. The Stourbridge Electric Lighting order has been transferred to the Shropshire and Worcester Electric Power Co., Ltd. Greystones is to have an electric generating station, and a company is being formed to exploit the undertaking. (Pages 175-176.)

SPECIFICATIONS in connection with several Australian telephone tenders may now be seen at the Board of Trade Commercial Intelligence Department, 73 Basinghall Street, London. Burnley Corporation invites tenders for a booster; at Edinburgh an extension switchboard panel is required, and tenders for stores are invited by Leeds, Islington, West Ham, and Sheffield. The Rawtenstall Corporation and the Islington Borough Council also require a large quantity of electrical machinery. New tramcars are required at Southampton, cables at Tunbridge Wells, and substation plant at Fulham. (Page 176.)

THE report of the Central London Railway shows considerable losses both in revenue and passengers carried for the past half-year. Dividends are declared, however. The Metropolitan Railway Co. reports an increase in revenue of nearly £4,000, and a decrease in expenses of nearly £6,000. To meet the expenses arising from the West Hampstead and Farringdon Street accidents, a sum of £4,500 has been taken from the reserve fund. At the meeting of the East London Railway Co. reference was made to the increasing difficulties of carrying on the undertaking in the absence of some arrangement for through working with the lessee companies, all of whose lines are now worked electrically. Statements have been issued by both the British Electric Traction Co. and Marconi's Wireless Telegraph Co. The former states that the question of paying the half-yearly dividend on the 6 per cent. cumulative shares due on February 15th will be left for decision until the annual meeting, owing to difference of opinion on the Board. The Marconi Co. states that a new audit of the accounts has been rendered, but it is expected that the annual meeting will take place early in March. (Page 178.)

THE three Bills relating to electric power supply in London will commence in the House of Lords. These Bills are now ready for first reading. We give particulars of several oppositions to private bills. (Page 181.)

DR. RUDOLPH GOLDSCHMIDT, in undertaking the compilation of the Paper presented last Thursday to the Institution of Electrical Engineers, set himself a difficult and laborious task. He has given in a compact form a series of generalised data relating to the performance of dynamos and motors, averaging the results of what has almost automatically become standard practice. Although there may be no absolutely new facts in the Paper, old facts are certainly presented in a new form, which will be of use to a large class of engineers. The aim of the author was not to standardise in the ordinary sense of the term, and he in no way sought to impose limits or otherwise to cramp the freedom of designers of dynamo-electric machinery. The series of curves of losses, efficiencies, and so on, are not intended as ideals to be worked up to in the production of standard apparatus, but represent what are the results that may be expected in average practice. No engineer, be he dynamo designer or only slightly versed in the ways of flux and ampere-turns, can keep in his head quantitative data of a long range, different sizes of machines of all types. There are numerous cases in which, although it is not necessary to work out detailed designs, approximate figures are required in planning out schemes, of the efficiency, inherent regulation, or some other property, which machines for certain purposes may be expected to have, and here, we think, Dr. Goldschmidt's curves will be found serviceable. Some of the speakers in the discussion lost sight of the fact that the results represented general averages, not referring to any special line of machines, and went out of their way to find designs which did not agree in every respect with the data in the Paper; but, as was pointed out by Prof. SILVANUS THOMPSON, it would be easy for designers to utilise the framework the author had provided, and plot upon it the corresponding particulars of machines with which they were acquainted.

THE fact that a considerable proportion of the Brighton consumers live over their shops has been handed down to us from a classical Paper of Mr. ARTHUR WRIGHT, and has now become almost proverbial; but it appears now that the Brighton resident is also not above availing himself of an excuse for not going to church on Sundays. An action for an injunction for nuisance against the Brighton Corporation in respect of their substation in North Road has been proceeding during the past fortnight, and it may be anticipated that judgment will be delivered to-day. The alleged nuisance is caused by the humming of the motor-generators in the station in North Road, which has been converted to a substation, and is supplied from the Corporation's large generating station at Southwick. Both sides admit that a humming noise can be heard in a church close to the substation, and the only question at issue is whether the noise is sufficient to interfere with the service, and distract the thought of the worshippers. In a case like this, in which the real question at issue could be settled at once by the judge going down to the spot and deciding the matter by his own observation, it is remarkable that it should be necessary to need expert evidence on both sides, and that no less than three experts, including two F.R.S.'s, should have to go down to Brighton to investigate the matter. The dispute is one that was certainly well adapted to being settled by arbitration, but, on the other hand, supply-station engineers and managers will doubtless be grateful to the Brighton Corporation and the Church party for allowing the action to come to Court, for it is, we believe, the first case in which an endeavour has been made to obtain an injunction in respect of a substation, and the case will be a useful precedent.

Mr. J. F. C. SNELL's Paper on the cost of electrical power for industrial purposes has been discussed at greater length at the Institution of Electrical Engineers than any other Paper we have had there for some time. It is on a question of vital interest to the electrical industry, and those who are interested in electric power distribution will be glad to hear that the adverse effect which the more pessimistic parts of the Paper might have had, has been more than counterbalanced by the

Digitized by Google

confident optimism of many of the supply station engineers. We have already pointed out that Mr. Snell's "correct" prices for power supply which he thinks should be charged by the existing electricity works are based on the premise that a trader is acting wrongly to offer a commodity below its present cost price, even if in doing so he can produce such a demand that the cost price with the more favourable output will be greatly less than the selling price. With this assumption we cannot agree. Many suppliers, moreover, have adduced figures to prove that they are by no means selling below cost price, as Mr. Snell imagines. His tables of figures for the costs of production in independent electrical plants were also criticised, and while he himself admits that they may be taken as minimum figures, and do not include the proper proportion of establishment charges, yet there is no doubt that the assumption cannot be made from first principles, as some are inclined to do, that works with their own generating plant are necessarily run less economically than if they buy their electrical energy. In the case of this Paper, the experiment of having simultaneous discussions in London and some of the Local Sections has proved a success. The discussion in Glasgow, which we report in this issue, was well up to the level of the debates on technical Papers there, and so many speakers desired to have a hearing that the Paper is to be taken again at the next meeting of the section. In London also it is evident from the written communications received, many of which are of even greater value than some of the spoken remarks, that the two evenings' debate did not exhaust the subject. For this reason, we owe a debt of gratitude to the Institution for giving us access to the written communications, so that we have been able to publish the pith of them while the Paper is still fresh in our readers' minds.

ARRANGEMENTS FOR THE WEEK

(TO-DAY), THURSDAY, JANUARY 30TH.

Royal Society.

4.30 p.m. Meeting at Burlington House, Piccadilly. Among the Papers down for reading is the following :—"On the Generation of a Luminous Glow in an Exhausted Receiver Moving Near an Electrostatic Field, and the Action of a Magnetic Field on the Glow so Produced," by the Rev. F. J. Jervis-Smith, F.R.S.

FRIDAY, JANUARY 31ST.

Royal Institution.

9 p.m. Evening Discourse by Prof. Ernest Rutherford, F.R.S., on "Recent Researches on Radio-activity."

MONDAY, FEBRUARY 3RD.

Institution of Electrical Engineers: Newcastle Local Section.

8 p.m. Meeting at the Armstrong College, when a Paper will be read by Messrs. T. F. Wall and S. P. Smith on "Experimental Determination of the Losses on Pole Shoes due to Armature Teeth."

Dick Kerr Engineering Society.

8 p.m. Meeting at Preston. Paper to be read :—"Notes on Commutation," by G. A. Juhlin.

TUESDAY, FEBRUARY 4TH.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Ordinary Meeting at the University. Paper to be read :—"Protective Devices for High-tension Transmission Lines," by J. S. Peck.

WEDNESDAY, FEBRUARY 5TH .

Dynamicables.

7 for 7.30 p.m. Dinner at the Trocadero Restaurant.

THURSDAY, FEBRUARY 6TH.

Institution of Civil Engineers.

8 p.m. Ordinary General Meeting at the Institution of Civil Engineers, Great George Street, Westminster. Paper to be read :—"Protective Devices for High-tension Transmission Circuits," by J. S. Peck.

Institution of Electrical Engineers: Leeds Local Section.

8 p.m. Smoking Concert at the Hotel Metropole, Leeds.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London. Paper to be read :—"The Present Position of X-Ray Measurements," with demonstration of apparatus, by Dr. Deane Butcher.

FRIDAY, FEBRUARY 7TH.

Institution of Civil Engineers: Students' Section.

8 p.m. Meeting at 25 Great George Street, Westminster. Paper to be read :—"Electric Hardening and Annealing Furnaces," by P. T. Steinthal. Mr. James Swinburne, F.R.S., will take the chair.

SATURDAY, FEBRUARY 8TH.

Junior Institution of Engineers.

6.30 for 7 p.m. Anniversary Dinner at the Hotel Cecil, London.

SERIOUS MAINS EXPLOSION ON THE WESTMINSTER NETWORK

A SERIOUS explosion occurred at six o'clock on Sunday evening on the Westminster Co.'s mains in Hamilton Place, which leads from Piccadilly into Park Lane. It appears that a fairly old vulcanised bitumen cable in bitumen casing crosses Hamilton Place at the point in question, and a short circuit occurred across all three conductors of this cable. The heat generated at the short, boiled the bitumen in the usual way, and the gas generated passed through the conductor into a service box in the pavement, and then through the pipe containing the service cables to a cellar in an area of Mr. Leopold de Rothschild's house (No. 5 Hamilton Place). Here an explosion occurred, and two windows of the house were broken, one of which was blown in from the force of the explosion. Alarm was immediately given, and the Fire Brigade was soon on the spot, as well as the officials of the Westminster Electric Supply Corporation, but the services of the firemen were hardly needed. Unfortunately, a second explosion occurred in the street on lifting a pavement cover a short distance away. The explosive mixture, of bituminous vapour and air, which, of course, penetrated here, was again the cause, but it is not quite clear how this was ignited. The occurrence is greatly to be regretted, as it is well known that on the Westminster mains a very complete system of examination and testing is in force. We believe we are right in our assumption that the lead covering and armouring of the cables is not bonded through, and an indication of faults is obtained by feeling the sheathing for shock when the boxes are lifted for inspection. The cable under the roadway has been abandoned, as it would be a considerable expense and disturbance to traffic to lift it.

Telegraph Traffic.—Cable communication with Beira was opened on the 25rd inst. This cable connects at Mozambique with the system of the eastern group of companies. The French Telegraph Co. repaired the break in their Paramaribo-Cayenne cable on the 24th inst., but their Cayenne Salinas cable gave out on the 25th inst. The Trinidad-Demerara cable, repaired on Jan. 16th, was again interrupted from Saturday until yesterday. Communication between Rome and Constantinople stopped on the 25th of this month, but was restored on the 26th, and on the 28th the cable between Alexandria and Larnaca ceased to operate. The "El Arich" and other landline routes have also suffered derangement. Telegraphic connection has again been restored with the Orkney, Shetland, and Faroe Islands and Iceland. Caister now appears in the list of stations from which Marconigrams may be despatched to ships at sea.

The Eastern Telegraph Co. was yesterday refusing all traffic to Australia and the East in consequence of the Egyptian land lines being down.

ELECTRICITY IN THE TEXTILE TRADE

By E. L. Hill

ALMOST the first requirement of the textile manufacturer is steadiness of drive, for this affects both the quality and output of his yarn; but uniformity of speed was unattainable until the application of electricity, and more particularly of three-phase electricity generated by turbo-alternators. The modern mill engine is a very fine machine of its kind, but it has all the disadvantages of low-speed reciprocating motion, viz., dead centres, want of balance, and varying angular velocity. These defects are inherent to its kind, and as long as such engines are used in textile mills, so long will the machines that they drive suffer from irregularities of speed. Gas engines at the present time need hardly be considered, since every defect of the slow-speed reciprocating steam engine is present in the gas engine in a markedly greater degree.

The modern mill engine is prodigal of space. By reason of its slow speed it is necessarily large, and, since its power is transmitted mechanically, much space is taken up by rope-races, pulleys, shafting, bevel, and other gearings. Moreover, the transmission losses are high, and increase rapidly as the plant is loaded up. The friction in the bearings and between gear wheels, and also the slip and creeps-in ropes and belts, become very serious items. The presence of slip caused by irregularity of drive can often be detected by the highly-polished surface of the pulleys.

The variation in angular velocity in the reciprocating engine is chiefly caused by the fewness of the impulses that its pistons receive per minute, only a few hundred at the most. The turbine, with its large number of blades, its many series of expansion, its purely rotary motion and its perfect balance, is necessarily a smoothly-running machine, and the impulses that its blades receive must be measured by hundreds of thousands per minute; it runs, in fact, at a constant speed. The alternator which the turbine drives is directly coupled to it, and runs at the same speed, and this, as will be seen later, has an all-important effect upon the steadiness of running.

Another great advantage of the turbo-generator is that it can be made capable of withstanding continuous over-loads for long periods without damage. The best modern practice divides the load in the textile mill between two machines, each of which is capable of withstanding whenever required an over-load of 100 per cent. for ten hours with a slightly higher steam consumption. Under normal conditions, both turbines share the work between them, but should one be stopped for examination or repair, the other can supply the whole of the power and lighting requirements of the mill at a small additional cost in coal. The extra capital outlay for two such turbines over one capable of driving the mill singly is surprisingly small, and is a very moderate premium to pay for insurance against possible loss caused by shut-down.

Compared with the size of a slow-speed reciprocating engine, pulleys, and rope-race, a turbo-alternator of equal power occupies about one-tenth of the room, and if the power is divided between two turbines they will not take up more than one-seventh of the room that the reciprocating engine would require

In the mill, power is transmitted to the various motors by means of suitable cables, which can be run and fixed anywhere. The losses in the mains at full load when a reasonable pressure is used need never exceed 2¼ per cent. Four hundred volts is the best pressure to adopt in most cases, as it is high enough to be economical in copper, yet not so high as to be dangerous or difficult to manipulate. With three-phase energy, which is far and away the best for textile mills, such a pressure has the further advantage of being suitable for lighting. With star-wound transformers, the lighting system can be wired between each of the three phases and the neutral point, the effective pressure on the lamps then being 230 volts. If a higher pressure than 400 volts is required, transformers become necessary for the lighting.

In the mechanically-driven mill, extensions of the premises often involve either excessive losses in transmission of power or the putting down of an independent plant. By the use of electricity, extensions only entail the running of cables and the fixing of motors. The extensions, moreover, need not follow rigid lines as in the case of mechanical drive, and the buildings can be placed anywhere convenient, and odd corners profitably employed.

With alternating current, the constancy of the frequency has an all-important effect on the steadiness of running. The speed of the motors depends almost entirely on the frequency of the supply, and is only affected to a small extent by variations in the voltage of the supply and the load on the motors. If, therefore, the frequency remains constant, the speed of the motors will not vary. It follows from this that motor-driven machinery can always run at the maximum speed that the fabric will permit. With uniform speed, fewer ends are broken, and no allowance need be made for sudden variations. With mechanical drive it is impossible to run at the maximum speed that the material can stand, because, owing to the irregularities of drive, that maximum would sometimes be exceeded. It is, therefore, necessary to fix on a lower speed, which entails a reduction in output. But with electrical driving the flyers, rings, and mules can always be run at the highest speed that the rovings can stand. This regularity of speed not only increases output, but also improves the quality of the yarn, so in both ways a better return is earned on the capital. The smoothness of running has, moreover, the effect of reducing the repairs bill.

Electrical energy can be easily and accurately measured, and, in consequence, when motors are employed a careful check can be kept on the different processes of manufacture. A machine that needs repair or a shaft out of alignment can be quickly detected and put right.

Another incidental advantage of the use of electrical power is that cheap lighting can be obtained for the mill, and from this it follows that the employees work under clean and healthy conditions.

Enough has been said to prove the advantages of electrical driving, and it may be of interest to examine roughly the methods by which the energy may best be made to do its work. The three ways to be considered are driving by a single motor, which takes the place of the steam engine, "group drive," and "individual drive." The group drive is far the most common, and is usually the most economical. In this system, one motor is used to drive one or sometimes two or three lengths of shafting, which, in turn, drive a number of machines through belting. The great advantage of such a drive is its low first cost, while its efficiency is high. Individual drive, in which each machine is worked by its own motor, entails a somewhat heavy initial outlay, but in certain cases it has advantages. As every machine is self-contained, any number of machines can be run with the maximum of economy,

Digitized by Google

as all losses in belts, shafting, and the like are avoided. The individual drive is specially suitable for weaving-sheds, where the horse-power of the shafting compared with that of the looms is high, and where a large percentage of the looms are constantly at rest. The looms in a weaving-shed are a more or less fortuitous collection of individual machines. One, ten, or a hundred of them can be stopped without interfering with the rest, and independent driving is often a great advantage. In a new shed it will mean a great saving in the building, as no provision need be made for long lines of heavy shafting. The shed, moreover, will gain materially in light through the absence of pulleys, and the looms can be placed in any position, and much valuable space can be utilised that with mechanical driving would be unavailable. Three-phase motors for driving looms of from $\frac{1}{3}$ to $2\frac{1}{2}$ h.p. can now be obtained that will attain full speed from rest within one to five seconds; they drive the looms either by belts or gearing. When belts are used, a device is employed to maintain an even tension. In the case of gear driving, friction or centrifugal clutches are employed, which save the motors from sudden shocks caused by the stopping of the loom, and prevent damage to the reeds, which would otherwise be caused should the shuttle stop short in its travel.

Group driving is usually the best in spinning mills because the process of spinning is a continuous one. From the breakers to the mules or rings, the material travels—or should travel—evenly onwards, and the raw cotton forming the bale reappears, less wastage, as yarn in the spinning room. A stoppage in any part of the process would affect the output of the whole.

Mules should always be driven on the group system, because their frequent reversals call for an amount of power installed far in excess of the average required, and in mule spinning the drive should always be arranged so that one motor works several mules. Ring and doubling frames, on the other hand, can often be advantageously driven by separate motors, although the capital cost will be higher. The power they absorb is regular, and does not vary continually as in mule spinning.

Rapid progress in the electrical driving of textile mills is being made, and by midsummer of this year almost 6 per cent. of the total spindles in Lancashire will be electrically driven.

THE LONDON ELECTRIC POWER BILLS

THE London Power Bills will come up for consideration first in the House of Lords. A number of further reports have been made to local authorities affected by these Bills:

The Parliamentary Committee of the London County Council recommend that petitions be lodged against the London and District Electricity Supply, London Electric Supply, and the London (Westminster and Kensington) Electric Supply Bills.

The Town Clerk to the Woolwich Borough Council, reporting upon the London Electric Supply Bill, states that the Bill would enable the Joint Committee in any event to supply energy within the Council's area for haulage and traction purposes without the Council's consent, and, failing agreement, would compel a reduction of existing prices generally. In regard to the London and District Electric Supply Bill, the company propose to compete with the Council throughout their area of supply for all power purposes and for light to the extent of 20 per cent. of the power load. With regard to the London (Westminster and Kensington) Supply Co.'s Bill, the effect of clause 8 would be to empower the company to supply the South-Eastern Railway Company with energy to be used on any part of their system, including that portion in the Borough of Woolwich. The Council having considered the Town Clerk's report and the observations of the Law and Parliamentary Committee thereon, resolved to present a petition against the London Electric Supply Bill and the London and District Electric Supply Bill. The Council's interests, it was held, were not sufficiently prejudiced to warrant any opposition to the London (Westminster and Kensington) Electric Supply Co.'s Bill.

The Paddington Borough Council, at its last meeting, considered the views of the Legal and Parliamentary Committee regarding the London (Westminster and Kensington) Electric Supply Co.'s Bill, the London Electric Supply Bill, and the London and District Electricity Supply Bill. The only proposals of the first-named measure which appeared to the Committee to affect Paddington were contained in the clauses relating to the laying of high-tension mains. The Committee expressed the opinion that if high-tension mains were laid through Paddington for the benefit of other boroughs, the Borough Council should choose the route of such mains. The Committee object to the purchase clause in the London Electric Supply Bill, inasmuch as the Paddington Council at present possesses special powers for purchasing the undertakings of one of the parties to the Bill, *i.e.*, the Metropolitan Electric Supply Co., Limited. The Committee, however, regard it as improbable that either of the Bills will become law in their present form, and do not consider that they endanger the interests of the Borough sufficiently to warrant the very considerable expenditure which would be necessary to effectually support the Council's opposition to the schemes. It is further suggested that the attention of Parliament and the L.C.C. should be drawn to the Council's objections to the proposals in the Bills for the nullification of the powers possessed by Paddington for the purchase of the Metropolitan Electric Supply Company's undertaking in the Borough, and also to the other points mentioned.—It was decided to communicate with the L.C.C., the Borough's representative on that body, and the Parliamentary representatives informing them of the Council's objections to the proposals, and requesting the influence of the representatives in securing the rejection of the Bills.

At the last meeting of the Middlesex County Council the Parliamentary Committee recommend opposition to the London Electric Supply Bill and the London and District Electric Supply Bill on general grounds.

The Hendon Corporation has decided to deposit petitions against the London and District Electricity Supply Bill and the London Electric Supply Bill, Hendon being included in the areas scheduled.

The Richmond Town Council will also petition against both Bills.

The Parliamentary Committee of the Stepney Borough Council, in a report issued on Monday, states that the London and District Electricity Supply Bill would seem, from the Stepney point of view, the most dangerous proposal made to Parliament in regard to the supply of electrical energy. In addition to claiming the power to give supplies to such undertakings as railways, tramways, and canals, without first obtaining the consent of authorised distributors, the company proposed to give supplies without obtaining consent to power users whose maximum demand exceeded 250 kw. It proposed also to give supplies to other consumers when able to quote a lower price than the authorised distributor. The committee also object that the Bill does not indicate definitely the prices proposed to be charged to consumers, leaving the Borough Council, as undertakers competing with the company, in the dark as to the rates against which they were called upon to compete. The committee consider the clause empowering the company to acquire the undertakings of other authorities by agreement as most objectionable, and express the opinion that the company should be compelled, at the option of an authorised distributor, to purchase the latter's existing undertaking on fair terms. With regard to the London Electric Supply Bill, the committee point out that the prices, not exceeding £5 per kw. per annum and 0·35d. per unit, at which the Joint Committee is obliged to give supplies to authorised distributors, are actually higher than the maximum prices at which the authorised distributors would be bound to supply to consumers if the Bill became law. The Bill was, however, far more satisfactory to the Council than the London and District Bill, as it was not proposed to invade the Council's area except as regards docks which it was desired to supply with energy for haulage traction. The committee has decided in favour of opposition being offered to both Bills.

Acting upon a recommendation by the General Purposes Committee, the Lewisham Borough Council will oppose both the London Electric Supply Bill and the London and District Bill.

THE GREENWICH BOILER EXPLOSION

THE Board of Trade inquiry into the boiler explosion which occurred at the Greenwich Works of the South Metropolitan Electric Light and Power Co., on December 20th, 1906, under circumstances already reported in ELECTRICAL ENGINEERING (Vol. I., page 24; see also Vol. II., page 1006), was concluded on Wednesday of last week at the Town Hall, Greenwich, when Messrs. A. A. Hudson and W. H. Hallett, the Commissioners appointed by the Board of Trade, delivered judgment.

The judgment commenced as follows :—This inquiry in many respects is remarkable. Though the inquiry has lasted a long time, the facts are comparatively simple, and the cause of the explosion not far to seek. A steel drum working at a pressure of 160 lb. per square inch was found to have developed a crack in the end-plate near the riveting for a length of 2 $\frac{7}{8}$ in., and a small jet of steam was issuing from it, yet no one in charge of the boiler, from the highest to the lowest, thought there was any danger, and no one took any step to shut down the boiler or reduce the pressure of steam. It has been urged that the drum was only four months old, had been supplied by a well-known firm, and had been thoroughly tested; but the fact pointed to something exceptional, and should have been taken as a warning that there must be something seriously wrong. The primary cause of the explosion was the supply of a badly constructed drum by the makers, the immediate cause being the neglect to reduce steam when a crack appeared.

The drum which exploded was a "thermal storage-drum," and was one of two connected with a Babcock & Wilcox boiler. It was constructed of mild steel plates, was cylindrical in form, with elliptical ends, and was connected with, and formed part of, the boiler.

The tests to which the boiler had been subjected were then described. The drum was first put into use at the company's works on August 18th, 1906, so that it had only been in use about four months when it exploded. During this short period of its existence it appears to have worked satisfactorily. A leak occurred in October, 1906, and another one later in the seams, to which no importance was attached, except that when the leak subsequently occurred (which led to discovering the crack in the end-plate which afterwards gave way), it was at first thought that the leak was due to a similar cause.

The appearance of this further leak, noticed first on December 17th, is then referred to, and it is recorded how no efforts were made to ascertain its cause until the following Wednesday, when a little of the lagging was removed, and it was discovered that there was a crack in the end plate of the drum 2 $\frac{7}{8}$ in. long, running in a line with the circumference and near the riveting. From this crack a jet of steam about 1 ft. long and $\frac{3}{4}$ in. in diameter was issuing. Upon this, Mr. Constable, the resident engineer, discussed the matter with Mr. Covell (of Messrs. Babcock & Wilcox), who subsequently telephoned to his firm, but neither considered that there was any danger. Mr. Constable then gave a written order to the shift engineers that the boiler was not to be let down, in order, as he said, not to increase the crack by changing the temperature of the drum; but he did not then report the discovery of the crack to his chief, Mr. Bowden. The reason, no doubt, that Mr. Constable sent for Mr. Covell was that he considered, as did also his chief, Mr. Bowden, that they had not yet taken over the drum from Messrs. Babcock & Wilcox, the terms of Messrs. Babcock & Wilcox's contract with the South Metropolitan Electric Lighting and Power Company being that the final payment was to be after six months' satisfactory working, and this period had not expired.

The visit of Mr. Shermer on the Thursday morning is then alluded to, after which Mr. Constable reported on the state of the boiler to Mr. Bowden. Mr. Shaw, engineering inspector of the National and General Boiler Insurance Co., was then sent for, and Mr. Bowden telephoned to Mr. Kolle, assistant manager of Messrs. Babcock & Wilcox, who appears also not to have anticipated immediate danger. Mr. Bowden's concluding words on the telephone to Mr. Kolle were, "We will see what Shaw says"; this was about twenty minutes to four. Mr. Bowden then sent Mr. Shaw to inspect the boiler, and in about fifteen or twenty minutes the explosion occurred, killing Mr. Shaw, who was in the act of examining the drum, and Mr. Coombes, the boiler-house foreman, who was then, or about then, removing some of the lagging. It was then twilight, and the heaviest load on the engines was just coming on; but it does not appear that the pressure in the boiler was beyond 160 lb. per square inch—its proper working pressure.

The nature and causes of the explosion are dealt with in a joint report of Mr. Carlton and Mr. Vose, who made the preliminary examination after the explosion. Shortly, the nature of the explosion was that the back end of the thermal storage-drum blew out, having fractured round the edge close to the rivets, while the drum, with the front end attached, was projected almost horizontally a distance of 95 yards into a neighbouring gas-works, penetrating in its course three stout brick walls before it came to rest, the third wall being 2 ft. thick.

After the explosion it was found upon an examination of the drum that a crack had, at the time of the explosion, existed two-thirds round the circumference of the end-plate, with a series of small cracks besides, leaving only $\frac{1}{32}$ in. to $\frac{1}{8}$ in. of sound metal, and that in one place this crack had penetrated entirely through the plate for a length of 2 $\frac{7}{8}$ in. This was the crack which had appeared on the outside. Other defects also appeared. All these defects were found to run round the knuckle, along the edge of a chain of deep indentations, which had been caused in fitting the end-plate into the shell of the drum at the works of Messrs. Babcock & Wilcox.

The process of manufacture of the end-plates of these thermal storage-drums was first to press the metal of the end-plate while hot in a die to the required shape, and, after they had cooled, to fit each end-plate into the shell by placing the flange of the end-plate into the last plate of the shell. By means of an hydraulic riveter, which could exert a pressure of 60 tons, the flange of the end-plate and the plate of the shell were then forced together, the metal of the shell and the end-plate in this last process being cold. The steel used in the drums was supplied by Messrs. Beardmore, and was made on the acid open-hearth process. During this fitting of the end-plate into the shell indentations to the depth of $\frac{1}{8}$ in. had been caused to the inside of the knuckle of the end-plate where the cracks before referred to were afterwards found. These indentations were caused by the snap-head of the riveter, which, instead of having been entirely directed against the flange of the end-plate, had partly come in contact with the inside radius of the end-plate at the knuckle. This, as Mr. McLaren reported to his firm after the explosion, was because the end-plate had been brought down too low into the shell-plate during the process before referred to. The effect of these indentations was to punish the metal very severely, and to cause distortions as well.

The Commissioners continue :—Though the work in the other part of the drum was described by Mr. Carlton as being of the highest class, we have no doubt that the indentations we have described showed bad workmanship, and this bad workmanship was the primary cause of the explosion. These indentations were not, according to the evidence of different persons in the employ of Messrs. Babcock & Wilcox, regarded as of any importance.

Messrs. Babcock & Wilcox contended that such indentations did not show bad work, and stated that numerous drums were sent out of their works with indentations, and several with as deep indentations as in the exploded plate. They also sought to shirk the responsibility for the defect in the end-plate by saying that the plates which Messrs. Beardmore had supplied them with were defective, and we have in consequence listened to exhaustive evidence as to the quality of the plates supplied by that firm to Messrs. Babcock & Wilcox, of which the plate used in the manufacture of the end-plate which exploded was one.

We have had, however, the benefit of very careful bending tests, made under the supervision of Mr. Carlton, and in the presence of representatives of Messrs. Babcock & Wilcox, and these tests, speaking generally, dispose of the suggestions of Messrs. Babcock & Wilcox of brittleness.

There was one test, however, which might have left some doubt in our minds had not exhaustive tests been made by Dr. Stanton, superintendent of the Engineering Department at the National Physical Laboratory at Teddington, and by Mr. Rosenhain, superintendent of the Department of Metallurgy and Metallurgical Chemistry in the same laboratory. These tests entirely disposed of the suggestion of inferior metal.

These tests, besides showing the good quality of the metal supplied by Messrs. Beardmore, demonstrated the injurious effect of the rough handling which the plate received at the works of Messrs. Babcock & Wilcox. We have no hesitation, therefore, in finding that the plate supplied by Messrs. Beardmore was of good normal quality, and that the fracture in the end-plate was in no way due to bad material. We also come to the conclusion that the cracks in the end-plate which caused the explosion probably existed to some extent at the time the boiler was tested by hydraulic pressure up to 240 lb., though probably not observable under ordinary internal examinations of the drum. The hydraulic test was a dead load, but when the live load—namely, 160 lb. of steam pressure—was applied; the cracks, in our opinion, increased, and this increase was partly due to the panting movement in the drum, caused by variations in the temperature of the drum, and the pressure in the drum arising from various causes.

The judgment then deals with the responsibility of the different persons concerned. It is stated that Messrs. Beardmore are in no way responsible, but the responsibility of the makers of the boiler is referred to as follows :—

Messrs. Babcock & Wilcox, on the other hand, supplied a drum with a defectively-constructed end-plate—that is to say, an end-plate injured by rough handling, due to bad workmanship. They are, therefore, primarily responsible for the explosion, and they have wasted some days in endeavouring to show that the defect in the end-plate was due to bad material. Mr. R. A. McLaren, their works manager, is responsible for sending out a bad end-plate from the works.

Digitized by Google

Mr. H. W. Bowden and Mr. Constable are both held partly responsible; and with regard to the responsibility of the former, the Commissioners remark :—"In the management of electrical power stations, when the chief engineer is an electrical specialist, as he should be, it seems to us desirable that some arrangement of the staff should be made so that the engineer's responsibility for the safe working of the boilers should be lessened, or transferred to an engineer having a thorough knowledge of the working of boilers :—

The judgment concludes :—

The sums which we order to be paid to the Board of Trade are as follow :—

	£
Messrs. Babcock & Wilcox	400
Mr. Richard Andrew McLaren	50
Mr. Bowden	50
Mr. Constable	30

In conclusion, we think it will remove any false impressions caused by this explosion if we place on record the fact that nothing has occurred at this inquiry to throw any doubt as to the safety of thermal storage-drums; but if they are badly constructed or are not worked under safe conditions, explosions, of course, will occur, just the same as in the case of any other boiler.

ITALIAN WATER POWER SCHEME LITIGATION

ON Tuesday, January 21st, in the King's Bench Division of the High Court, Mr. Justice Grantham and a special jury had before them the case of Girolame Taddei and Paoli Bellami, against John D. Pender, Lord Hay and Richard Enfield, executors of the late Sir John Pender, for breach of contract made in December, 1889, between the plaintiffs and Sir John Pender on the one part, and Mr. Jabez S. Balfour on the other part, whereby it was agreed to purchase from the plaintiffs certain water rights and concessions in Italy for the purpose of manufacturing electricity for the lighting of the City of Rome and other uses. The defendants denied liability, and counter-claimed for £12,000 unrecovered on a previous judgment against plaintiffs. Mr. Horridge, K.C., M.P., and Mr. C. C. Scott appeared for the plaintiffs, and Sir Edward Carson, K.C., M.P., Mr. Rufus Isaacs, K.C., M.P., and Mr. Spencer Bower, K.C., were for the defendants. The plaintiffs are two Italian engineers, and the transactions of which the case forms the subject took place in 1889, and has reference to property some 17 miles from the City of Rome. In 1889 it occurred to the plaintiffs that the water power at a Villa near Rome, known as Villa D'Este, could be utilised for the purpose of supplying electrical power to the City of Rome. Accordingly they came to England, and saw the late Sir John Pender, then chairman of the Eastern Extension Telegraph Co., who was favourably impressed with regard to the scheme, and said he was anxious to form a company to be called the Italian General Works Electrical Enterprise Co., with the object of applying for concessions from the Rome municipality. Plaintiffs were instructed to go back to Italy to see if they could arrange the matter, the result being that they entered into an agreement, by which they agreed to purchase the right to use the water power in question for 600,000 lire (£24,000). They also arranged for the sale of the National Educational College, in the villa of D'Este, for 450,000 francs (£18,000), and both those agreements were entered into and completed. Plaintiffs paid a deposit of £2,000 for the water rights, and they guaranteed payment of another £2,000 as against the completion by the purchasers of the educational college on the site. Eventually, however, the negotiations fell through, and the concessions for the supply of electricity were never obtained.

On Wednesday, January 22nd, Mr. Horridge, K.C., M.P., continuing his opening statement, said plaintiffs had spent large sums of money in obtaining concessions for the water power in question. Sir John Pender and those associated with him got so far as the preparation of the prospectus of the Italian General Works Electrical Enterprise Co. The plaintiffs said they were entitled to £50,000 as soon as they satisfied the promoters of the company that they could get the concessions. Plaintiffs got conveyances of the property drafted at the Tivoli, and went to very great expense. This was a great and magnificent scheme for lighting Rome by electricity, but unfortunately it was ruined by the scarcity of money at the time, caused by the Argentine revolution and the Baring crisis.

Mr. Girolame Taddei, one of the plaintiffs, said he had many meetings and consultations in London with Sir John Pender and others. He gave them all the explanations they required as to the scheme, and everybody was satisfied. He and his partner had spent about £20,000 over the scheme altogether. On Thursday witness was cross-examined by Sir Edward Carson. He considered that he ought to have been paid £50,000 by Sir John Pender before he obtained any concessions at all, and before he obtained from the municipality of Rome the right to break up the streets and lay down wires, &c., for the supply of electricity. If they had obtained the municipal concessions they could have used the electricity for industrial purposes in the neighbourhood, and on their own ground. It was necessary to have the £50,000 in order to carry through the scheme and get the water rights. He said he believed it was a fact that there were petitions against the scheme from Tivoli and from Rome and from various users of the water. He knew of the petitions, but he did not inspect them. If they had got the £50,000 they would have obtained the water rights and all difficulties would have disappeared. Once he had got the concessions anyone would have been glad to enter into the matter, as it would have been a very profitable affair. Even if they had not been able to introduce electricity into Rome there would have been a field of operations outside the city.

On Friday, January 25th, Mr. Robert Powell Mackenzie, an engineer, was examined. He said the scheme was a splendid one, and there was no doubt that if the money had been paid there would have been no difficulty in obtaining the concessions, neither would there have been any difficulty in obtaining powers to get an order of public utility and break up the streets of Rome.

On Monday Mr. Horridge, for the plaintiffs, said Sir Edward Carson and he had arrived at terms which were satisfactory to his clients. The case was then accordingly withdrawn from the jury.

NUISANCE FROM BRIGHTON CORPORATION MOTOR-GENERATOR STATION

THE hearing of this case, previously reported on p. 116 of our last issue, was continued on Wednesday last week. His Lordship said it appeared from Mr. Wilson's evidence that the nuisance only commenced when two particular machines were working, and he suggested that it would be advisable for the experts to take special observation of these. Arrangements were accordingly made that after Wednesday's evidence the case should be adjourned till the following Friday, for the inspection on Thursday of the engines while in motion. The Rev. Mr. Roberts, lately curate of St. Mary's Church, stated that the noise from the electrical works interrupted the performance of his clerical duties. Mr. Astbury then opened the case for the defence, stating that the Corporation had exercised their statutory powers in a most reasonable manner, and had done everything possible to meet the plaintiffs. It was utterly impossible to detect any noise unless one knew that it existed and especially listened for it. Counsel maintained that if they could get the judge to go down to Brighton for ten minutes there would be an end to the case. Mr. James Swinburne, F.R.S., said he inspected the sub-station on April 10th, 1907, when it was working at its maximum load for such a time of the year. The station contained four rotary transformers, and three of these were working at the time of his inspection. Machines of that description were practically silent when moving, but most electrical machines made some humming noise. Witness was of opinion that the rotary transformers were well designed and well made, and on proper foundations, and he could find no fault with the station in any way. He had visited the church at Brighton; he went over the entire building and listened carefully at different places, especially those indicated by the Rev. Mr. Heath. He agreed there was certainly audible a slight noise in various places in the church when everything was quiet. From place to place it varied, but in no part of the church was the noise such as to constitute a nuisance. It was a low musical note, a little higher than the lowest G on the manuals of the organ. The noise was completely drowned by anyone speaking and by anyone passing in the street outside the church building.

When the hearing was resumed on Friday, Mr. Swinburne told the judge that he had gone down to Brighton with Professor Boys and Mr. Christie the previous day. Mr. Christie remained at the works, and various combination machines were run. Witness and Prof. Boys went to different parts of the church, and the experiment proved that machines three and five did not create a noise. Mr. Arthur Wright, the Corporation consulting engineer, stated that the noise could only be heard if extreme attention was paid to it. Professor Boys said in his evidence that the noise was so slight that no word in the English language could properly describe it. He did not think that the elastic support to machines would stop the noise, but he would recommend this being tried if an order to stop the noise was made.

Several other witnesses living in the neighbourhood stated that the works did not annoy them, since the steam plant was superseded by the present machinery.

On Saturday, the Town Clerk of Brighton gave evidence, and Professor Boys, recalled, said he believed the noise was a ground sound. He suggested that they should place the church columns on elastic supports, and this might afford a remedy, but he could not guarantee it as an absolute cure. The case was adjourned until to-day (Thursday).

Faraday House Old Students' Association.—The fourth annual dinner will be held at the Queen's Hotel, Leicester Square, on Friday, February 21st at 7.30 p.m., with the President, Mr. G. W. Partridge, in the chair. Tickets may be obtained from the honorary secretary, Faraday House, Southampton Row, W.C.

STANDARD PERFORMANCES OF ELECTRICAL MACHINERY

DR. R. GOLDSCHMIDT, in his Paper read last Thursday before the Institution of Electrical Engineers, remarked that comparatively little information of a definite nature as to standard performances of motors and dynamos is generally available. For instance, a purchaser of a 10 h.p. motor will look in vain for information as to what the efficiency of such a machine ought to be. If there were any standard rule prescribing that the efficiency should be 85 per cent., manufacturers would probably endeavour to obtain 85½ per cent., and it might become a point of honour to exceed the conditions of the rules. Suggestions for standard performances, standard power-factors, standard efficiencies, &c., from a private quarter may, however, be acceptable, and, after criticism and discussion, may become useful as a private standard.

Although they might not be quite indisputable, he continued, such normal figures would be of assistance in many respects. The mechanical engineer cannot be expected to know what will happen if, say, in a machine tool or crane a gear is arranged to be cut out and the motor speed reduced. I will mention one case. A 5-h.p. 2-phase induction motor for a crane had been fixed at as low a speed as 500 revs. per minute, the overload capacity had been specified as 150 per cent., and the frequency was 50 ~. It does not appear at first sight that the current consumption of such a motor is about double that of a machine running 250 revolutions faster, or that a somewhat smaller overload capacity would have improved matters. The mechanical parts of the crane had been finished, and the motor had to be built contrary to the better judgment of "all who knew." In such a case a timely warning would have been of value. In compiling the Paper I have avoided as far as possible dealing with such generalities as are to be found in text-books, and have endeavoured to demonstrate the results by means of curves, restricting myself to comments on these only.

All electric motors and dynamos work through the interaction of the magnetic flux and the ampere-turns. Whatever machine one may select, whether it be an induction motor, an alternator, a synchronous motor, or a direct-current machine, one always finds a cylinder carrying ampere-turns on its circumference and a magnetic flux entering this cylinder in a radial direction. The torque is the product of both, and calling "power" the kilowatts reduced to 1,000 revs. per minute, then "Power" = KW at 1,000 revs. = const. × ampere-wires × flux = const. × AW × F.

With direct-current machines, polyphase alternators, and polyphase induction motors, the constant averages $0{\cdot}165 \times 10^{-9}$; with single-phase machines it averages $0{\cdot}145 \times 10^{-9}$. By "ampere-wires" is understood the total number of conductors which are cut by a plane in the middle of the armature at right angles to the shaft, multiplied by the number of amperes per conductor. With induction motors the ampere-wires are those of the rotor only. The flux is the sum of all fluxes entering the armature from all poles together. It is naturally possible to obtain a certain "power" with an infinite number of combinations of ampere-wires and fluxes. In actual practice the figure for both will be of the same order if we express AW in 10^3 (kiloamperes) as unit, F in 10^6 (megalines; 1 megaline = 167 kapplines).

The conditions fixing AW and F vary for every class of machine, and are not always those of economy of design. With direct-current machines the commutation, with alternating motors the pull-out, with alternators the voltage drop, come into consideration. Of the two factors, AW and F, working together to produce the output, one, F, is constant, while AW increases with the load. AW tends to destroy F, and causes sparking or voltage drop. Therefore, in order to produce a good machine F must not be too weak. It is due to these well-known conditions that F and AW do not actually vary so very much. The effect on the efficiency, which is the chief item about to be considered, is very small indeed, even if F varies by quite a considerable amount.

There are certain sections required for F and AW, as the density must not exceed a certain figure, limited by heating or saturation (teeth). Further, the length of path which the flux and AW have to flow in is also very nearly fixed, as both are interlinked, and have to surround one another. Therefore, if the AW and the size are given, the copper losses due to AW are pretty well fixed, as well as the core loss, provided the speed at which the flux revolves is known.

DIRECT-CURRENT MACHINES.

Fig. 1 shows F and AW for different KW at 1,000 revs., for machines having no commutating poles. In most cases these fluxes are identical with the most economical flux, especially with moderate speeds. With commutating poles the flux may be 25 per cent. or even 35 per cent. less.

The core loss caused by a certain flux F, is proportional to the speed. Taking 1,000 revs. per minute as the unit of speed, Fig. 2 shows the core loss at different fluxes. It must be understood that there are eddy-current losses, which increase as the square of the speed, the hysteresis only being proportional to it. But in our case the machine with more flux is a different machine, more iron section being provided. This is the reason why we are entitled to make the core loss practically proportional to the speed.

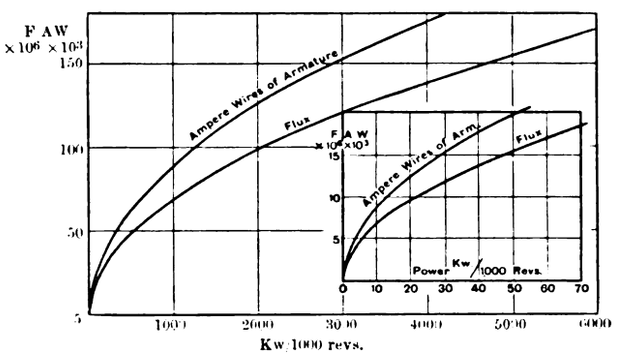

FIG. 1.—DIRECT CURRENT. STANDARD FLUXES AND AMPERE-WIRES OF ARMATURE.

The armature copper loss is dependent on AW only, as shown by Fig. 3.

In Fig. 4 the AW, copper, core, and total losses have been drawn up for 100-kw. 500-rev. machines designed with different fluxes, and it will be noticed that the total losses are practically unchanged (that is, only between 4,550 and 5,000 watts) if the flux is altered from 21 to 37 megalines. The losses with well-designed machines cannot be far from this minimum, as it is very expensive to provide surface for extra losses.

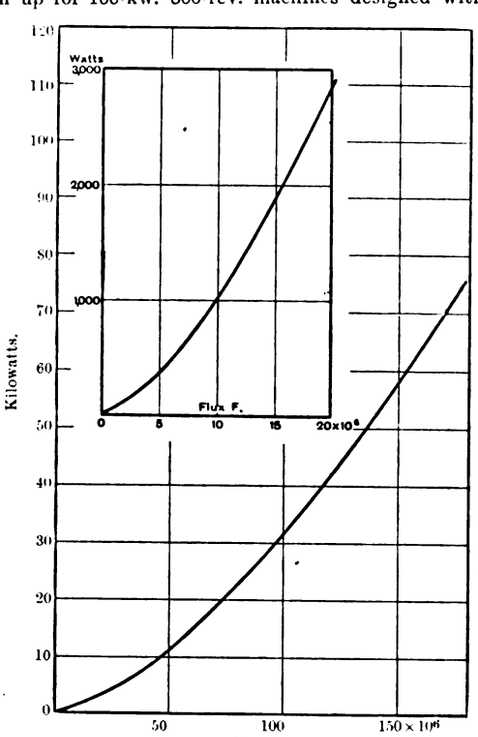

FIG. 2.—DIRECT CURRENT. CORE LOSS AT 1,000 REVS. PER MINUTE WITH DIFFERENT FLUXES.

For convenience sake I have combined Figs. 1, 2, 3 to form Fig. 5, where the losses are expressed in percentages of the output, and as a function of the "power" KW at 1,000 revs. By expressing them as a percentage, the core loss is now independent of the speed, whilst the copper loss is inversely proportional to it. As unit of speed we take again 1,000 revs. per minute. The ampere-turns of the field magnets are a function

Digitized by Google

of armature ampere-turns and flux, the former demagnetising and the latter requiring to be driven through the air-gap. These ampere-turns have to surround the flux coming from the armature, which fixes their mean path, so that there exists a law which connects the power of a machine with the losses in the field.

I will define the expression "field ampere wires" as the field ampere-turns per pole multiplied by the number of poles

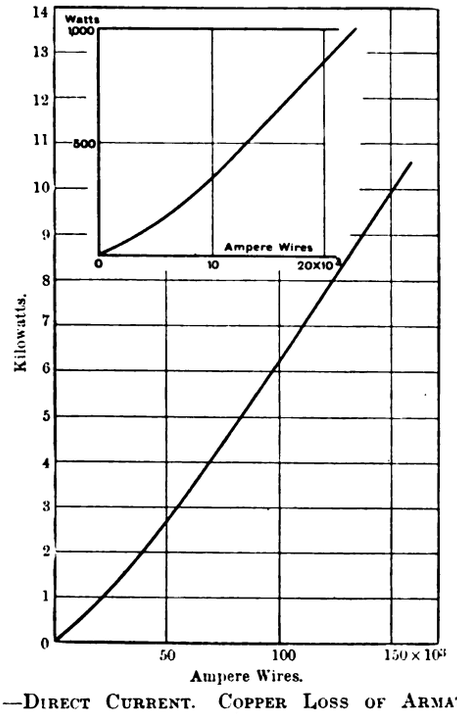

FIG. 3.—DIRECT CURRENT. COPPER LOSS OF ARMATURE WITH DIFFERENT AMPERE-WIRES.

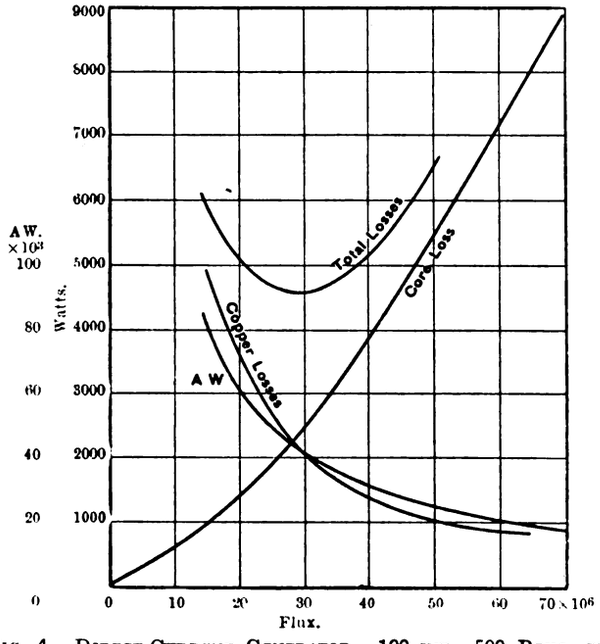

FIG. 4.—DIRECT-CURRENT GENERATOR. 100 KW., 500 REVS. PER MINUTE, LOSSES IN ARMATURE, WITH DIFFERENT FLUXES AND AW.

and multiplied by 2. The field AW and the losses as a function of the power are shown in Fig. 6. The losses are again expressed in percentages of the output, and, for correction, require to be varied in inverse ratio to the speed, 1,000 revs. per minute being again taken as normal. It may be noted that with large machines the field AW is about 25 per cent. more than the armature AW, and that 1,000 AW is about the lowest figure found with very small bi-polar machines. In machines with commutating poles the losses in the main poles are reduced, but this reduction is made up for by the losses in the commutating poles.

It remains to consider the friction losses. The most difficult question is that of the brush friction, but here also there exists a definite relation between current, current density in the brushes, and voltage drop, coefficient of friction, and friction losses. Also the commutator diameter can be approximately determined from the output; so that, choosing 200 volts and 1,000 revs. as normal, a curve can be plotted (Fig. 7) giving the percentage brush-friction as a function of KW at 1,000. These figures vary inversely as the voltage and directly as the speed. The bearing friction and windage are practically independent

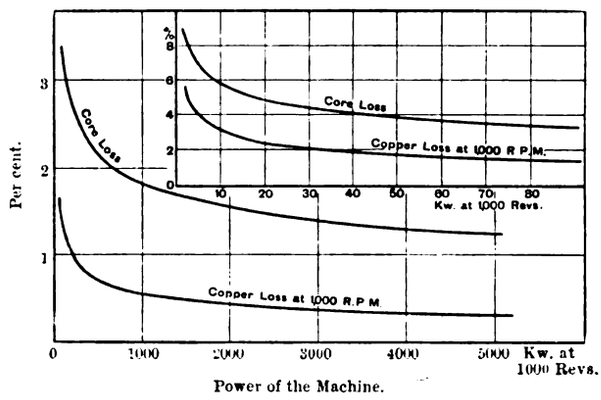

FIG. 5.—DIRECT CURRENT. ARMATURE CORE AND COPPER LOSSES IN PER CENT. OF OUTPUT.

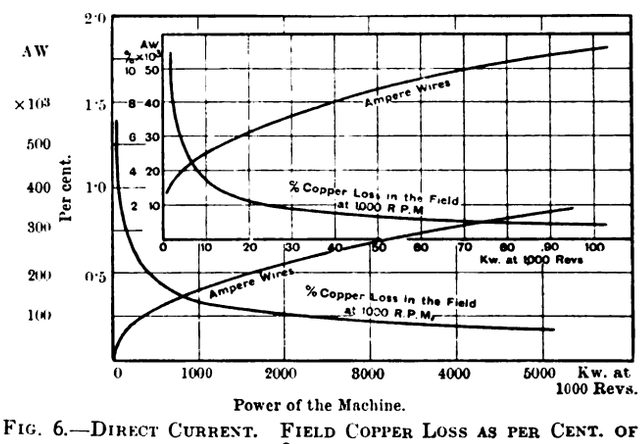

FIG. 6.—DIRECT CURRENT. FIELD COPPER LOSS AS PER CENT. OF OUTPUT.

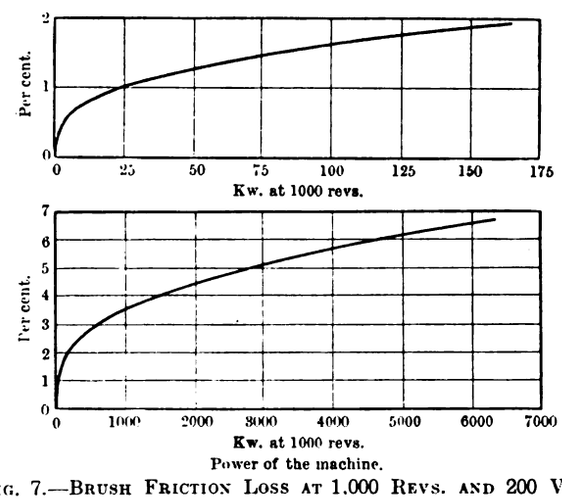

FIG. 7.—BRUSH FRICTION LOSS AT 1,000 REVS. AND 200 VOLTS.

of the "power," and depend almost solely on the angular velocity—that is the revs. per minute. Fig. 8 gives practical average figures for this class of friction.

The voltage drop in the brushes expressed as a percentage may be taken as $\frac{200}{\text{volts}}$. It is somewhat less with high-current and somewhat more with high-voltage machines. With copper brushes it may drop to about $\frac{100}{\text{volts}}$, but ought not to be assumed to be lower.

The total efficiency has been plotted in Figs. 9 and 10 for different speeds and as a function of the actual output (not

Digitized by Google

"power" in this case) of the machine, Fig. 9 giving the efficiencies of dynamos up to 5,000 kw. In Fig. 10 the abscissæ represent brake horse-power, but naturally motor and dynamo efficiencies are practically identical, so that Fig. 10 can also be used for dynamos. The voltage has been assumed to be 500 volts. If the voltage is different, a correction may be carried out in the brush friction and brush drop. The comparatively low efficiencies at very high speeds are due chiefly to friction and core loss. Figs. 9 and 10 give only the full load efficiency. An idea of the performance with smaller loads can be gained by referring to the curves giving the losses in detail.

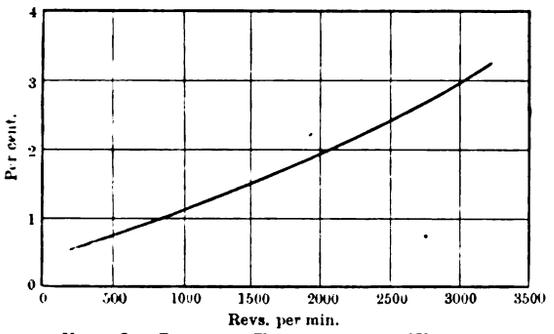

FIG. 8.—BEARING FRICTION AND WINDAGE.

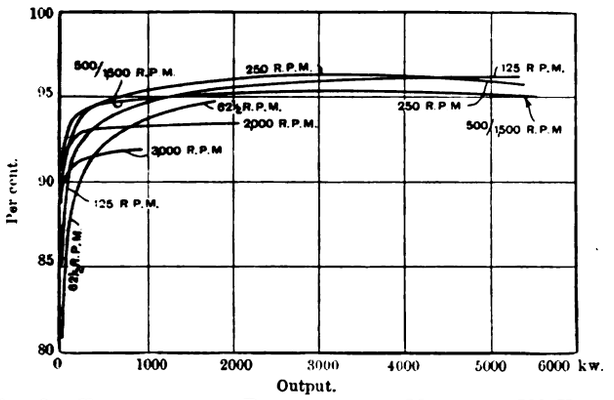

FIG. 9.—EFFICIENCIES OF DIRECT-CURRENT MACHINES, 500 VOLTS.

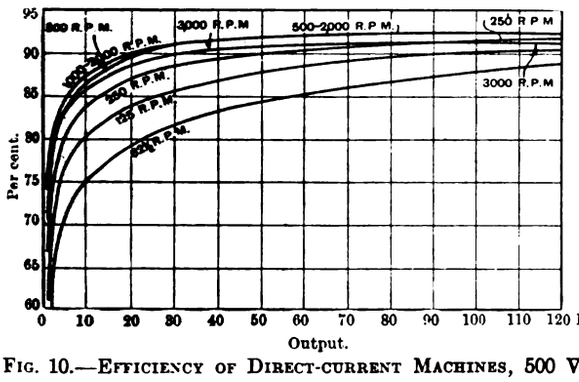

FIG. 10.—EFFICIENCY OF DIRECT-CURRENT MACHINES, 500 VOLTS.

ROTARY CONVERTERS.

The efficiency of a rotary converter may be obtained from the efficiency of the corresponding direct-current machine, making allowance for the losses on the alternating-current slip rings. For this purpose the curves in Fig. 7 may be used, reducing the friction found in this way to about one-half. This is naturally only very approximate. The output of a direct-current machine can be increased by a certain percentage, if used as a rotary, with 3-phase current by 33 per cent., and with 6-phase by 90 per cent. As the power-factor is not always unity, and a slight deviation from this reduces the output again. it cannot be assumed that the latter is increased by the full amount, but only, say, by 20 and 40 per cent. respectively. For approximate estimates the following formulæ may be used :—

$g_r = \frac{g}{0{\cdot}93 + 0{\cdot}07 \times g}$ for 3-phase, and $g_r = \frac{g}{0{\cdot}81 + 0{\cdot}19 \times g}$ for 6-phase, where g_r is the rotary efficiency and g the efficiency of a direct-current machine which is $\left(\frac{1}{1{\cdot}20} - 1\right) = 17$ per cent. and 28 per cent. smaller; g is to be taken from Figs. 9 and 10. Thus a 500-kw. direct-current machine at 250 revs. would as a 3-phase rotary have an efficiency of $\frac{94{\cdot}7}{0{\cdot}93 + 0{\cdot}07 \times 0{\cdot}947} = 95$ per cent.

ALTERNATORS.

The task of developing standard efficiencies for alternators is a very difficult one, as the law fixing the size of the machine is very complicated if the number of poles and the diameter are small. We can speak of the "output" of the field and the "output" of the armature separately. Our output formula KW at $1{,}000 = 0{\cdot}165 \times AW \times F$ refers to the armature only. Now, if we wish to make a good machine with not too much

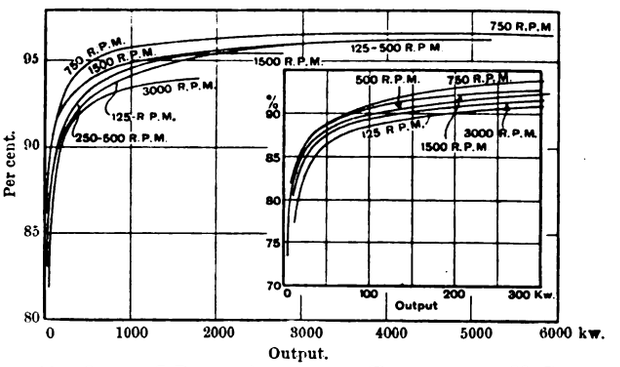

FIG. 11.—2- AND 3-PHASE ALTERNATOR EFFICIENCIES, 50 CYCLES.

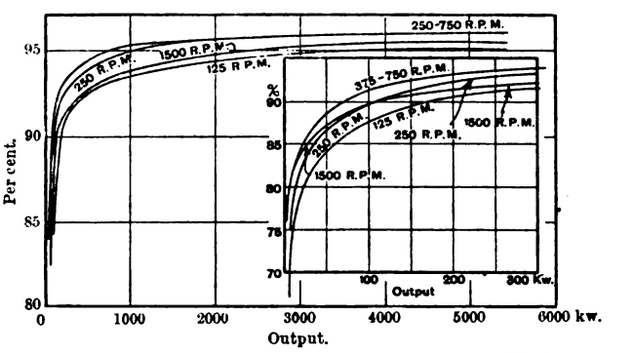

FIG. 12.—2- AND 3-PHASE ALTERNATOR EFFICIENCIES, 25 CYCLES.

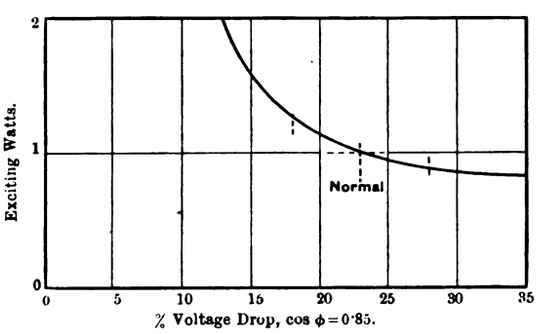

FIG. 13.—VOLTAGE DROP OF ALTERNATORS.

voltage drop, the AW of the field must be a multiple of the AW of the armature, say, three or four times as much. The flux in the field exceeds that in the armature by the amount of the leakage flux. Consequently the "output" of the field must be considerably more than that of the armature. As the field in the case of modern alternators is generally inside the armature, its mean diameter is smaller than that of the latter. Consequently it is often a difficult matter to provide room for sufficient AW and F, and the output of the whole machine has to be reduced. With machines below 5—6 ft. in diameter and a moderate number of poles this difficulty is always experienced. In such cases the output of a certain size of machine may be considerably increased by the admission of a higher voltage drop or by compounding.

On account of these difficulties I decided not to reproduce here the curves for the detail losses of alternators, as they would have been too numerous, but to give the results only. Figs. 11 and 12 show the efficiencies of medium-volt polyphase alternators for 50 and 25 ~ respectively, the power factor being unity. The falling off of the efficiency with very high speeds due to the friction and core loss will also be noticed here. In comparing alternating-current with direct-current machines,

Digitized by Google

large alternators are found to be slightly more efficient than large direct-current machines, on account of the commutator losses of the latter, but the reverse is the case with small machines where only small currents have to be dealt with on the commutators and where the alternators require considerable excitation.

To find the efficiency of single-phase alternators it must be remembered that the output of a certain machine as a polyphase alternator is about 50 per cent. more than for single-phase. The losses of the latter may therefore be taken as those of a 50 per cent. larger polyphase machine.

Generally speaking, if g is the efficiency of the 50 per

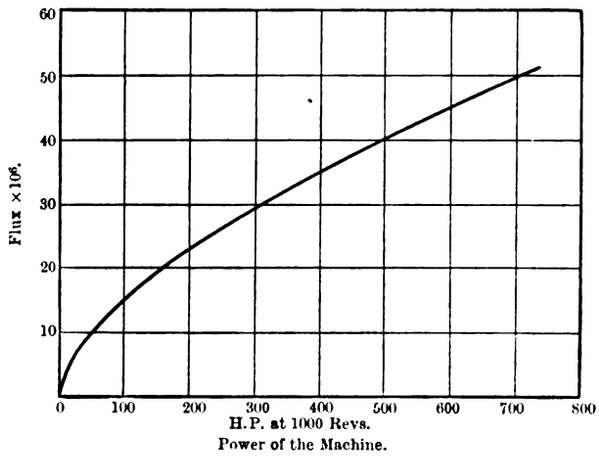

FIG. 14.—INDUCTION MOTORS. FLUXES.

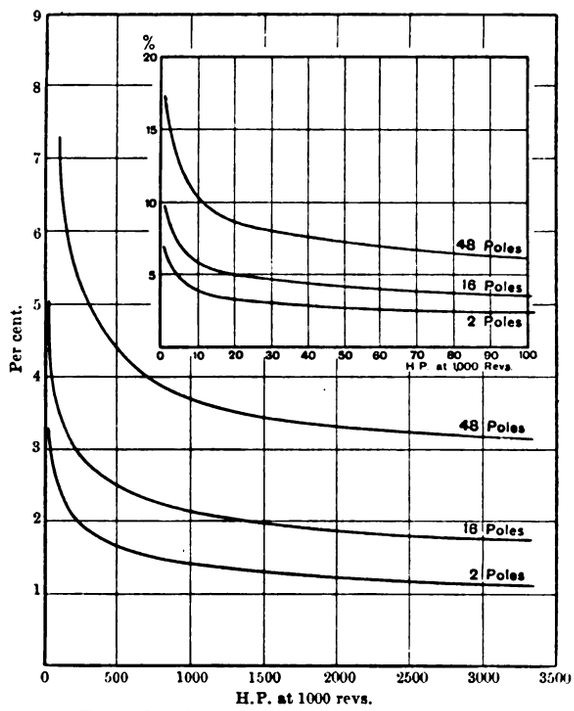

FIG. 15.—CORE LOSS OF INDUCTION MOTORS.

cent. larger polyphase alternator, the efficiency of the single-phase machine is—

$$g_1 = \frac{g}{1{\cdot}5 - \frac{g}{2}}.$$

If the power-factor is 0·85, the output of a certain machine is reduced 15 per cent. (actually the output of the armature only), while the excitation losses rise. It may therefore be stated approximately as—

$$g_{0\cdot85} = \frac{g}{1{\cdot}3 - 0{\cdot}3 \times g}.$$

I have pointed out what great influence on the size of machine the permissible voltage drop has. Therefore it is advisable not to specify it higher than can be helped. As a rule, one finds about 7½ per cent. drop specified with a power-factor of 1, and 23 per cent. with a power-factor of 0·85. Calling the excitation watts with this drop (23 per cent.) 1, and plotting a curve "exciting watts as function of the drop," the curve Fig. 13 is obtained.

INDUCTION MOTORS.

Efficiency.—The design of induction motors is far more definite than that of alternators, so that I may venture to reproduce a curve for the normal flux as a function of the "power" h.p. at 1,000 in Fig. 14. The overload capacity is the chief determining factor for these fluxes. In our case they refer to machines for

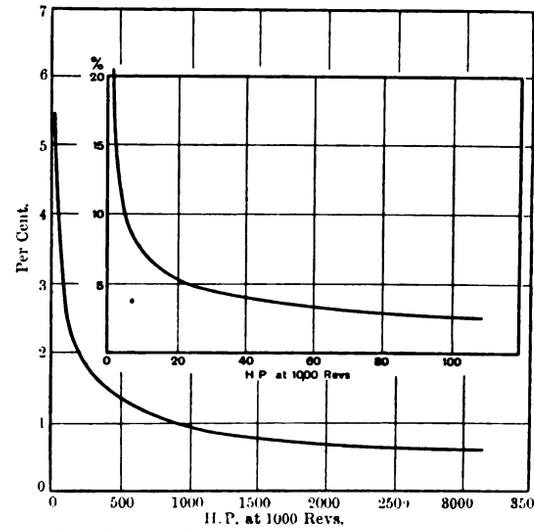

FIG. 16.—COPPER LOSS OF 4-POLE INDUCTION MOTORS.

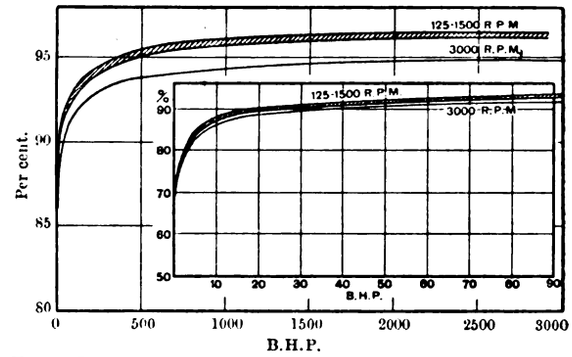

FIG. 17.—EFFICIENCY OF 50 CYCLES INDUCTION MOTORS, POLYPHASE.

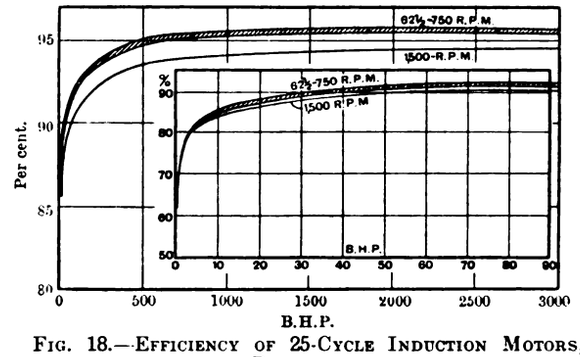

FIG. 18.—EFFICIENCY OF 25-CYCLE INDUCTION MOTORS, POLYPHASE.

about 125 per cent. overload capacity. With large and high-speed machines this figure is somewhat higher, owing to the fact that considerations of economy become important when AW and F are chosen. The percentage core loss and copper loss for different powers are shown in Figs. 15 and 16. In induction motors the percentage core loss is also independent of the speed, and of the periodicity, if plotted separately for different numbers of poles.

The copper losses have been plotted for 4 poles and 50 ~ only. Here it has to be borne in mind that the percentage copper loss increases as the square root of the number of poles, and in proportion to the periodicity. The reason for this is that with an increasing number of poles the output falls proportionately, but the mean length of turn is reduced as the length of the end connections decreases. With different frequencies the copper losses remain constant, whilst the output falls with the periods.

Digitized by Google

Figs. 17 and 18 show the complete efficiency curves for 50 and 25 ~ for polyphase machines. Fig. 19 gives the efficiency of single-phase induction motors for 50 and 100 ~ . In these curves the most striking feature is the fact that the efficiency is almost independent of the speed. It has been possible to show a narrow shaded area within which the efficiencies fall for any speed between 125 and 1,500 revs. per minute. Since the percentage core loss falls and that of the copper and friction loss rises as the speed goes up, the total losses remain nearly constant for a certain output. A comparison will show that the difference between the efficiencies of direct-current machines and alternating-current induction motors is not considerable. Single-

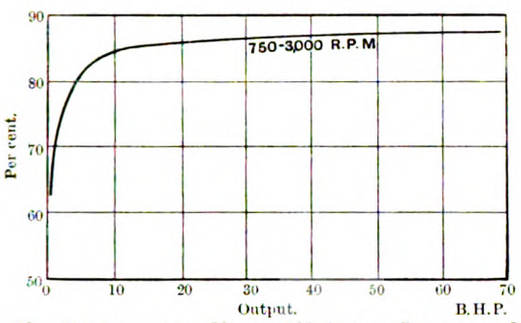

FIG. 19.—EFFICIENCY OF 50 AND 100 CYCLES INDUCTION MOTORS, SINGLE PHASE.

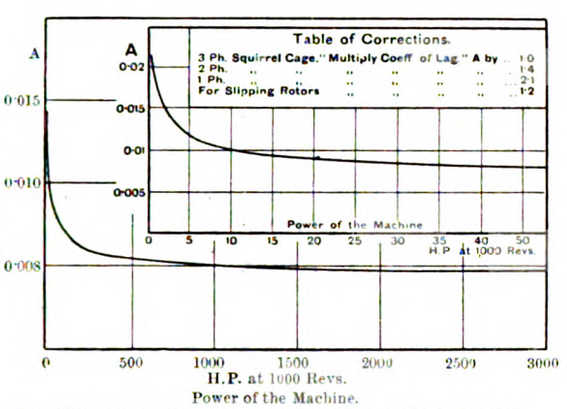

FIG. 20.—COEFFICIENT OF LAG OF INDUCTION MOTORS.

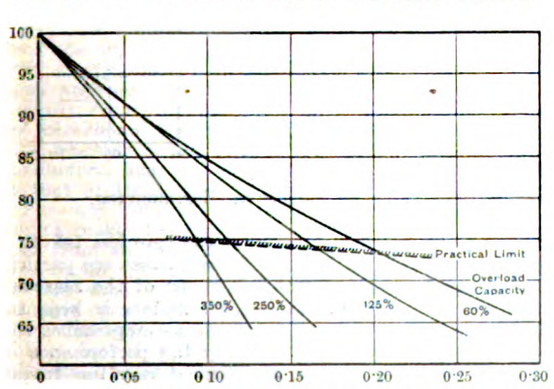

FIG. 21.—POWER FACTORS OF INDUCTION MOTORS.

phase motors naturally are considerably worse than both (Fig. 19).

Power Factor.—In saying that the efficiencies of direct-current and induction motors are practically identical, we have to restrict this to the real efficiency, the apparent efficiencies naturally being much worse with the latter class of machines. It is often important to know clearly beforehand what the power factor is likely to be before deciding on the speed, as a few revolutions may often convert a bad motor into a moderately good one. It is hardly practicable to draw a great number of power-factor curves which might enable one to read off the figures at a glance, as there are too many items influencing the power factor, namely, the size of machine, expressed by the "power" h.p. at 1,000 r.p.m., the number of poles, and the overload capacity. The air-gap also influences the power factor, but, as hitherto, this detail of design is taken account of in determining the "size," that is, the power of the machine. Instead of a great number of curves for Cos ϕ we use the two Figs. 20 and 21.

It is well known that the power factor of an induction motor greatly depends on the leakage of the machine, this leakage being smaller the smaller the air-gap, the larger the diameter, and the lower the number of poles. Apart from this latter item the leakage only depends on details of design, so that a factor which is an expression for the tendency to admit leakage can be plotted as a function of the "power" of the machine. We will call this factor the "*coefficient of lag*," A. All details of design have been crammed into this coefficient, and it has been

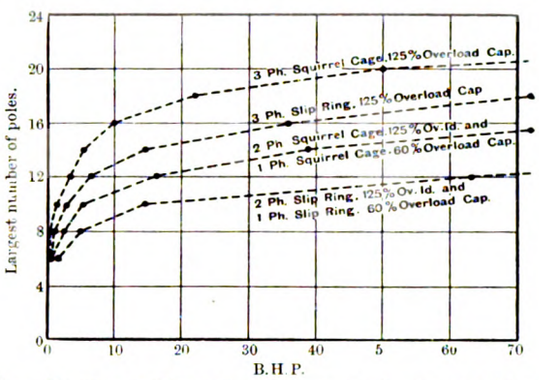

FIG. 22.—LIMIT NUMBER OF POLES OF INDUCTION MOTORS.

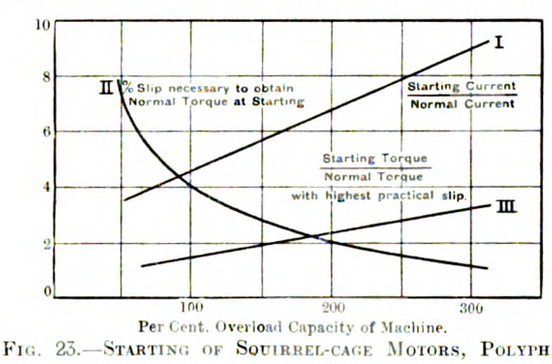

FIG. 23.—STARTING OF SQUIRREL-CAGE MOTORS, POLYPHASE.

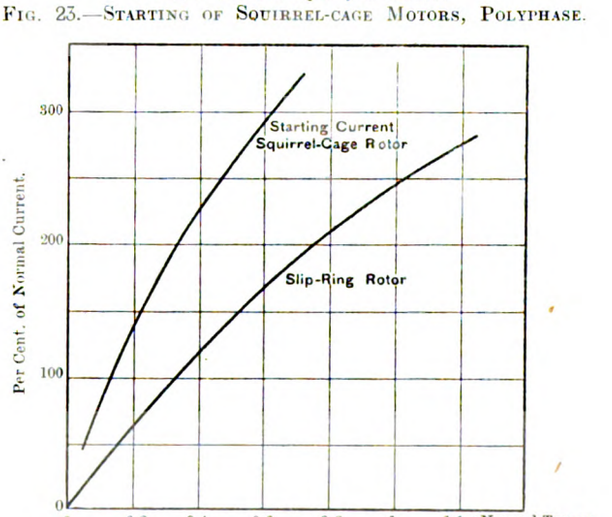

FIG. 24.—STARTING CURRENT OF SINGLE-PHASE MOTORS.

so selected that if multiplied by the number of poles Heyland's leakage factor appears.

Fig. 20 shows the coefficient of lag A dependent on the "power" h.p. at 1,000 for 3-phase motors with squirrel-cage rotors, whilst Fig. 21 directly gives the power factor at normal load for different overload capacities, dependent on the product "A × number of poles."

The coefficient of lag A in Fig. 20, referring to 3-phase squirrel-cage motors, is smaller than with any other class of motor, so that 3-phase squirrel-cage machines have the highest possible power factor. A has to be multiplied by the following constants: with 2-phase machines by 1·4, with 1-phase machines by 2·1.

In all cases where the rotor is a wound one the coefficient of lag increases another 20 per cent. I have drawn a line in Fig. 21

Digitized by Google

which represents the line of desirable practical limits, which only in exceptional cases ought to be exceeded. To make this still clearer the chart, Fig. 22, has been added, giving the highest number of poles a motor ought to be built for, the overload capacity being 125 per cent. in the case of polyphase and 60 per cent. with single-phase machines. It is necessary to point out that, when finding the coefficient of lag for single-phase motors from Fig. 20, this is to be taken at an abscissa for 50 per cent. larger output, as the "size" of a single-phase machine is 50 per cent. larger than the corresponding 3-phase one.

The Starting of Polyphase Squirrel-cage Motors.—The starting performance of a slip-ring motor where resistance is inserted in the rotor is too well known to be mentioned here, and it does not offer any special points which depend on size or design. The starting of squirrel-cage motors, however, often causes uncertainty as to the current consumption and the torque obtainable. We have to distinguish between machines being thrown straight on to the line and those started by means of a starting transformer, which reduces the voltage on the motor terminals.

If thrown straight on to the line, the current taken by the motor depends on the overload capacity it has been designed for, the current being larger the stronger the motor. Fig. 23 shows in a curve the approximate ratio $\frac{\text{starting current}}{\text{normal current}}$ dependent on the overload capacity. With very bad machines

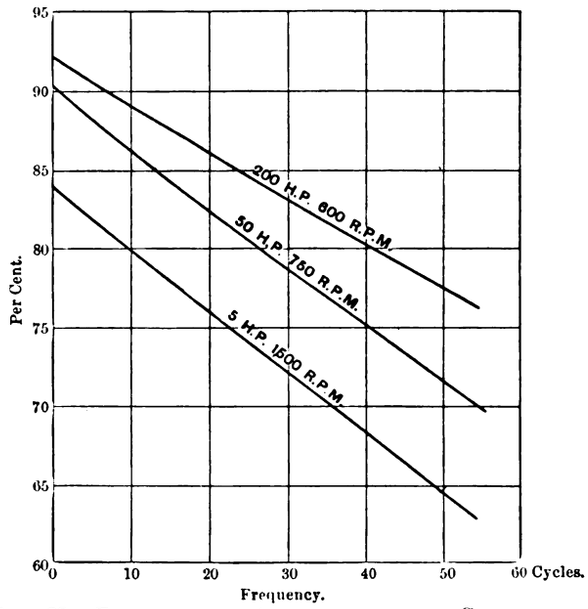

FIG. 25.—EFFICIENCY OF ALTERNATE-CURRENT COMMUTATOR MOTORS.

this ratio is somewhat smaller than that given here, due to the high no-load current. It will be noticed that with 125 per cent. overload capacity the starting current is about five times the normal current. If we wish to obtain a starting torque equal to the running torque, the rotor must have its resistance adjusted to give the percentage of slip as shown by the curve II. in Fig. 23. In some cases, especially with American machines, a good efficiency is not regarded as of great importance compared with good starting qualities. Also, short-circuit rings of the squirrel-cage are made of very high resistance metal, and slips of 6 and, with small machines, even 10 and 12 per cent. are considered quite permissible. In this case very high starting torques can be obtained. Curve III. shows about the highest starting torque practicable. Very often the windings are switched in star connection at starting, being in delta at normal load, in order to reduce the starting current. Then the starting currents are reduced, together with the torques, to one-third of the figures given in Fig. 23.

Starting of Single-phase Motors.—Single-phase induction motors with slip-rings are as a rule started with choking-coils, and squirrel-cage machines with resistances as a means of splitting the phase. Only rarely are condensers employed. Whatever means are used for phase-splitting, certain practical limits are encountered which without very much difficulty may also be followed up theoretically. I have given in Fig. 24 the starting current of single-phase motors as a multiple of the normal for different starting torques, the overload capacity being assumed to be about 75 per cent.

Maximum Voltage.—Before concluding the section on induction motors, I should like to allude to a question often asked, What is the maximum voltage for which a motor can conveniently be built? When ought a transformer to be used with the motor? This naturally depends very much on the design. Often the end brackets are too tight to take high-voltage end connections, and questions of detail of design have to be taken account of. If this is not the case, I may say that the voltage of an induction motor ought not to be so high that with large machines the current falls below $2\frac{1}{2}$ amperes and with small machines below $1\frac{1}{2}$ amperes.

SINGLE-PHASE COMMUTATOR MOTORS.

The real efficiency of a single-phase commutator motor is generally worse than that of a similar machine of the induction type, though the efficiency of the latter is not particularly good. The cause of this is chiefly to be attributed to the losses in the resistance connections between armature winding

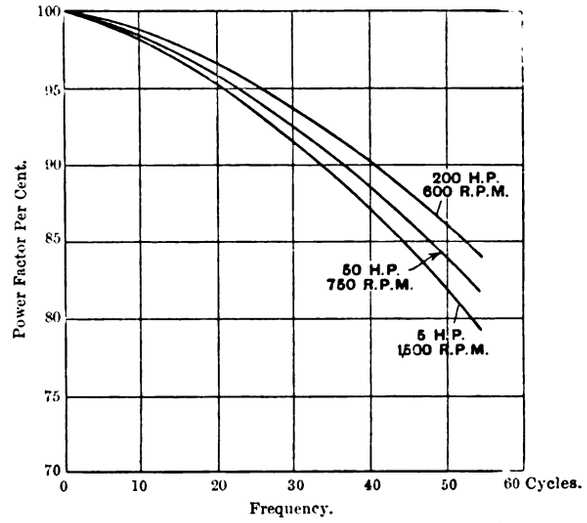

FIG. 26.—POWER FACTORS OF ALTERNATE-CURRENT COMMUTATOR MOTORS.

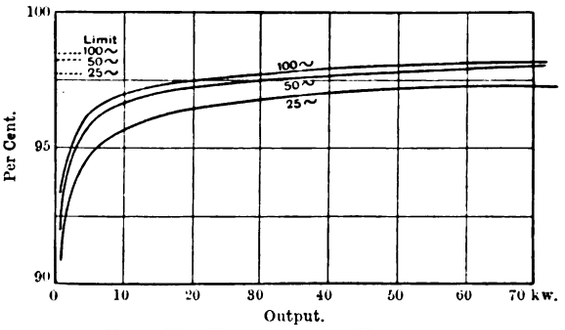

FIG. 27.—TRANSFORMER EFFICIENCIES.

and commutator lugs and to the enormous core loss taking place in the whole body of the machine. These losses are particularly high with high frequencies, and this is one of the reasons why generally the frequency of single-phase motors is kept as low as possible, so that actually its performance approaches that of direct-current machines. But naturally the performance of an induction motor would also be excellent at very low frequency, though it would under no condition approach the perfect behaviour at starting of the commutator motor. As characteristic motors I have chosen a small, a medium, and a large machine—5 h.p. at 1,500 revs. per minute, 50 h.p. at 750 revs. per minute, 200 h.p. at 600 revs. per minute—and efficiencies and power factors have been plotted as a function of the periodicity (Figs. 25 and 26). The power factors of Fig. 26 are those of plain single-phase commutator motors with compensating winding. They may be improved by using machines of the Latour and Winter-Eichberg type or by applying special means of other kinds to raise the power factor, generally at a sacrifice of 1 or 2 per cent. in the efficiency.

TRANSFORMERS.

Transformer efficiencies at normal load only do not always serve very well as an indication of the real quality of the apparatus, less so than in the case of the average motor and dynamo. This is true, at all events, with lighting transformers. With power transformers the normal efficiency is quite a useful figure.

Digitized by Google

The efficiencies plotted in Fig. 27 are not the normal but the maximum figures obtainable from a certain transformer—that is, when core and copper losses are equal. Usually it is possible to shift this maximum somewhat, putting it with lighting transformers near half-load, with power transformers near full load. By stating the maximum efficiency only, the curves in Fig. 27 will prove useful, even for finding efficiencies at very small loads, if one only takes account of the fact that one-half of the losses are core losses and the other half copper losses, which vary as the square of the output.

I have not extended the scale of the KW beyond 70 kw., as such a transformer as a rule has as good an efficiency as a 700-kw. one. The following may be given as efficiency limits: 100- ~ transformers 98½ per cent., 50- ~ transformers 98¼ per cent., 25- ~ transformers 97¾—98 per cent.

DISCUSSION.

Dr. SILVANUS P. THOMPSON, F.R.S., who opened the discussion, said that although he had only been able to go through the Paper in a very hasty manner, it had struck him as being a really valuable contribution, for it gave a means, at any rate—if it did not give a great deal more—of studying the comparative values of designs for different sources. He had not yet been able to examine whether the curves would fit the data known to him, but in any case it would be possible for designers to plot on the same framework the corresponding values of machines with which they were acquainted, and thus see whether the points so plotted came anywhere near those on the curves, and in this way the curves would be of great use. But there was, he thought, something to be desired in the interpretation of the diagrams in the Paper. It was not quite obvious which of the curves were derived purely from experience and which were calculations from first principles. If he was not mistaken, they were nearly all derived from experience, and corresponded to actual average performances from actual machines. At the same time, if any of them were derived or derivable from first principles, it was well that it should be stated that they were not dependent upon any empirical result obtained from any particular make of machine. He next dealt with the early portion of the paper, in which the main principle of the paper was laid down, of comparing all machines on the basis of the kilowatts which the machine in question would give out at 1,000 revolutions per minute. He criticised Dr. Goldschmidt's use of the word "power" in this connection, and suggested some other name, such as "powerage," as being more suitable; the author's definition of this quantity was "kilowatts at 1,000 revolutions per minute," which was equivalent to watts per revolution, in considering a machine which gave a certain number of watts at full load at a certain speed, and they had then the statement that the number of watts per revolution was equal to a certain constant times the total number of ampere wires round the armature of the machine multiplied by the total flux coming in or out from all the poles. It resolved itself into a very simple expression, and the constant did not depend upon anybody's particular make of machine. It was derivable literally from first principles. Dr. Thompson then wrote upon the blackboard the familiar formulæ for the e.m.f. and current of a machine in terms of the speed, number of poles, armature conductors, flux, &c., and deduced from them a formula similar to that of Dr. Goldschmidt for the total watts output.

For any and every continuous current machine, of anybody's make, the watts per revolution were equal to the total flux from all the poles multiplied by the ampere wires all the way round multiplied by a constant which could not be greater or less than $0{\cdot}166 \times 10^{-8}$. The constant given by Dr. Goldschmidt was 0·165. Thus they were in agreement, only he (Dr. Thompson) said that 0·166 was the absolute and unalterable value of the constant for continuous current machines, whereas Dr. Goldschmidt had given it as the average for continuous current machines, polyphase alternators, and polyphase induction motors. Could it be any different for polyphase alternators or polyphase induction motors? It could, because the real power of polyphase alternators or induction motors was not the same as the volts and amperes multiplied together in the sense in which it was in continuous current machines. It would be true for polyphase alternators and induction motors assuming there was no trouble from the form factor question if the power factor were unity. If it were less, then the constant would be smaller than 0·166. This might in some cases be compensated for by the circumstance that, taking the form factor and the root mean square into account, the value that would be otherwise raised 10 per cent. if the value of the amount were raised 10, would go down by the same amount because of the power factor. The two effects belong to one another, and therefore they would have nearly the same value for the constant of these other machines. For single-phase machines, according to Dr. Goldschmidt, it was 0·145. He did not understand the particular result, because he could not understand how it could be very much lower unless the statement was to be believed that the power factor of single-phase machines was always a bad one, or that its form factor for the virtual value was always abnormally low. Fig. 1 was an exceedingly interesting diagram in which he presumed, as the result of experience, the values were plotted in curves of the armature wires all the way round, and the flux in terms of the watts per revolution. The two curves in Fig. 1 were parabolic in outline, and they showed, he presumed, as the result of experience, that there was for machines that had a similar number of watts per revolution about the same proportional height between the curves, and if they took the scales into account—the flux being given in millions and the ampere wires in thousands—it appeared that the ratio of the total flux from all its poles to the ampere wires all the way round was constant. The ratio of one to the other was 800 for all machines apparently. Why should this be so? Apparently because they would have trouble from a machine if this proportion were seriously departed from. If they had too much copper and too many ampere wires on the armature in proportion to the flux from outside, then there would be too much distortion or demagnetisation, and probably commutation troubles. If they required a machine to work without trouble in the commutation, the total loading of the armature must not be too great in proportion to the total flux coming in. Apparently it was something of that sort which determined that there should be this proportion of 800, and certainly it simplified the work of designing if experience showed such a fixed proportion as that. He had not been through all the curves, but he imagined that the paper contained a fund of most valuable information as to what was the average practice for particular classes of machinery when compared one with the other, and it was an exceedingly simple and rational basis to take the same number of watts per revolution. Therefore, so far as he was able to appreciate the paper, he desired to express his thanks to Dr. Goldschmidt for having put things on to such an exceedingly interesting and useful basis for consideration.

Mr. V. A. FYNN said the author gave 0·145 as the co-efficient for single-phase machines and 0·165 for two-phase. He also stated that, "with induction motors the ampere wires are those of the rotor only. The flux was the sum of all fluxes entering the armature from all poles together." He took it that the author was dealing with a two-phase machine, with the resultant of the two fluxes which were really present. If the same thing was done for a single-phase induction motor, then the co-efficient would not be the same, because the flux coinciding with the main stator winding contributed nothing whatsoever to the torque of the machine. It was simply there for the purpose of taking the energy inductively from the stator to the rotor, and it was the rotor itself which was producing the field. Therefore, if the resultant flux was taken as 1·41 of the main flux, the whole of this was not effective for torque purposes, and therefore the coefficient for the single-phase motor should be lower; he made it roughly about 0·115. This held good for induction motors, but if they dealt with conduction motors then there was only one flux in the machine, and that was produced by the field winding on the stator, and the coefficient ought, as far as he could see, to be practically the same as for the continuous-current machine. It really came to this: that in the single-phase machine there were two fluxes at right angles in space differing in phase by 90 degrees, and only one of these produces torque. In the two-phase machine there were two fluxes at right angles in space, and also at right angles in tune, and both of them produced torque.

There was another point which he would like to mention, and that was in connection with single-phase commutator motors. The author stated:—"The real efficiency of a single-phase commutator motor is generally worse than that of a similar machine of the induction type, though the efficiency of the latter is not particularly good." He supposed that the author had in mind in these remarks conduction machines only. The Paper also mentioned the "plain single-phase commutator motor," which he presumed was the series machine. (Dr. Goldschmidt: That is so.) In that case, no doubt, the power factors were roughly correct, but if the motor was worked at some 40 per cent. or 50 per cent. above the synchronous speed, as it should be, then they were too low. The efficiency curves, he thought, were most distinctly too low. He could remember motors built by Ganz & Co., in 1888 and 1890, in large quantities at 5 h.p., with 75 per cent. efficiency. He suggested that the curve in Fig. 25 should be put up roughly as follows:—If machines with a shunt characteristic were referred to, then the 5 h.p. curve should at least come up to 70 on the 50-cycle line, an increase of about 6 per cent. The 50 h.p. machine should come up 9 per cent. also on the 50-cycle line, and the 200 h.p. also roughly 9 per cent. These were good conservative figures. If the machine was a series conduction one, then all the efficiencies might be wrong by another 3 per cent. If it was a series induction machine, they would be, as a rule, the same; in fact, in some cases a little lower than the machine with a shunt characteristic. He thought this distinction between single-phase motors with shunt and series characteristics might very well be introduced into the Paper, although it must, of course, be on quite general lines, because the difference between the two machines was very marked indeed.

Mr. J. C. MACFARLANE (Messrs. Crompton & Co., Ltd.) read some remarks, which are given in a slightly abridged form below:—The first thing that I wish to draw attention to in

Digitized by Google

Dr. Goldschmidt's valuable Paper is a reference near the beginning to a 5 h.p., two-phase induction motor for crane work, which runs at the low speed of 500 revs. on a 50-cycle circuit, and which also has a large overload capacity. Dr. Goldschmidt's Paper would be a valuable one, indeed, if it prevented buyers of electrical plant from making such mistakes as this. The combination of low speed and high frequency in induction motors is a very common error made by buyers of such motors, and the trouble they cause to the manufacturer, due to this, does not appear to be appreciated by them. Turning now to Fig. 1, it would appear that Dr. Goldschmidt has selected two curves, one representing the flux or magnetic loading of an armature as a function of the output at 1,000 revs., the other representing the ampere wires, or electrical loading of an armature also as a function of output at 1,000 revs., and it may be noted that the corresponding ordinates of those two curves bear a fixed ratio to one another. This ratio is approximately 800 : 1, *i.e.*, for any "power" whatsoever the magnetic loading of an armature is given by the curve as 800 times greater than the electric loading of the same armature. I cannot understand why Dr. Goldschmidt has selected this ratio in preference to any other ratio; nor can I see that any fixed ratio will suit the case—for I have known quite modern machines which have this ratio as great as 2,000 : 1, that is, the magnetic loading is 2,000 times as great as the electric loading of the armature. And I have also known machines having this ratio as small as 250 : 1, that is, the magnetic loading in this case is only 250 times as great as the electric loading of the armature. Dr. Thompson, in one of his Howard lectures before the Society of Arts, has recently given this ratio as about 1,000 : 1, but it must be remembered that this figure depends to a very great extent on whether a machine has an armature core length which is abnormally great compared with its diameter, or whether it has a core length which is abnormally small compared with its diameter. The very long machines will usually have a high ratio of magnetic to electric loading, whereas in narrow machines this ratio will usually be low. The machines quoted above, *i.e.*, the machines in which the magnetic loading was 2,000 times the electric loading, and the machines in which this ratio was 250 : 1, were quite normal machines, so far as core length goes. Another thing that may be noticed about the curves in Fig. 1 is that these are parabolas, and I should like to ask Dr. Goldschmidt why he has selected these curves for the purposes of this lecture. A little later on Dr. Goldschmidt makes two statements, which I consider are not quite correct. The first is :— In most cases these fluxes are identical with the most economical flux, especially with moderate speeds. The second is that in commutating pole machines, the flux may be 25 per cent. or 35 per cent. less than the flux given by the curves in Fig. 1. I presume he considers these are about the most economical fluxes for interpole machines. I do not know whether Dr. Goldschmidt refers to economy in the sense of electric and magnetic losses, or whether he refers to economy in material, but in neither of these cases are his statements correct. For in the case of electric and magnetic losses it is a well-known fact that the maximum economy is to be obtained when the sum of the constant losses of a machine is equal to the sum of the variable losses of a machine. Put more clearly, this means that the core loss, plus the shunt loss, should be about equal to the armature copper loss, neglecting for the moment the commutator losses. Taking the losses given for an 100-kilowatt machine, and adding these core and shunt losses together, you will find that they are exactly double the armature core loss. If we go further than this, and add to the constant losses the brush bearing and wind friction losses, and add to the variable losses the brush drop, we shall find that the case will be still further aggravated. With regard to economy in material, the maximum economy in material is to be obtained when the sum of the cost to the iron and steel, &c., in the magnetic circuit, plus the cost of the shunt copper, is equal to the cost of the armature copper. Or, for the interpole machines when the sum of the iron and steel costs, plus the shunt copper cost, is equal to the cost of the armature copper plus the cost of the interpole copper. What has been said may be more briefly put as follows :— The electric and magnetic losses in any machine are a minimum when the total losses in the magnetic circuit are equal to the total losses in the electric circuit. Also the cost of the material in any machine is a minimum when the cost of the material in the magnetic circuit is equal to the cost of the material in the electric circuit. I have with me some figures on two machines, one of which has the same ratio of magnetic to electric loading as given by Dr. Goldschmidt's curves in Fig. 1. The first of these machines is a non-interpole machine, and has an output of 470 kilowatts at 1.000 revolutions. The second machine is an interpole machine, and has an output of 475 kilowatts at 1.000 revolutions. The total magnetic loading of the first machine is 50.000.000 C.G.S. lines, and that of the second is 30.000.000 C.G.S. lines, *i.e.*, the magnetic loading of the non-interpole machine is 54 per cent. greater than that of the interpole machine. The electric loading of the first machine is 60.000 ampere wires, and that of the other machine is 100.000 ampere wires, *i.e.*, the electric loading of the interpole machine is 60 per cent. greater than that of the other. The total losses of the first machine amounted to about 14½ kilowatts, and the total losses on the second machine amounted to about 13 kilowatts. (It will be noticed that the total loss in the interpole machine is about 10 per cent. less than in the non-interpole machine.) The loss in the electric circuit of the first machine was 3·5 kilowatts, and the loss in the magnetic circuit was 11 kilowatts, *i.e.*, giving a ratio of 3 : 1 in favour of the magnetic circuit losses. The loss in the electric circuit of the second machine, *i.e.*, the interpole machine, amounted to 6·2 kilowatts, and in the magnetic circuit amounted to 6·8 kilowatts, making a ratio of 1·1 : 1 in favour of the magnetic circuit. Note that the losses, in the case of the interpole machine, in the electric and magnetic circuits are practically equal, whereas the losses in the case of the non-interpole machine are about 3 : 1, which tends to prove the rule given above. With regard to costs, the total cost of the material in the non-interpole machine came out at about £154, whereas in the case of the second interpole machine the cost came out to be about £128. *i.e.*, therefore there is about 20 per cent. more material on the non-interpole machine than there is on the interpole machine. The material in the electric circuit of the first machine cost about £12, and the material in the magnetic circuit of this machine cost about £142, giving a ratio of about 12 : 1, whereas in the interpole machine the electric circuit material cost about £38, and the cost of the magnetic circuit material amounted to £90, making a ratio of only about 2½ : 1. Although the interpole machine does not appear to be designed to give quite the most economical distribution of material, it has a considerable advantage over the non-interpole machine in this respect. It will be readily seen from the above figures, and also for other reasons, that the fluxes given by Dr. Goldschmidt in his curves, Fig. 1, are not by any means the most economical fluxes either from the point of view of efficiency or the economy of material. The temperature rise on both these machines was approximately the same, that on the interpole machine being slightly better if anything. As the magnetic loading in the non-interpole machine is about 46,000,000 C.G.S. lines, and the electric loading in this machine is about 60,000 ampere wires, then the ratio of magnetic to electric load is about 800 : 1, whereas in the interpole machine this ratio is about 300 : 1. The non-interpole machine is therefore a very similar machine to that which would be obtained by designing on the curves in Fig. 1, and the armature core, armature copper and shunt losses obtained from tests, compare very well with the figures obtained from the curves (Figs. 2, 3, and 6). The object of the above discussion is : (1) To show that the selection of a fixed ratio for the magnetic to electric loading of an armature is inadmissible, for in practice this ratio varies greatly, and although the author's method may give efficiencies within 1 per cent. or 2 per cent. in most cases at full load, yet it will not give any idea of the relative values of the various core and armature losses, &c., within the machines. This is important, because of the estimation of the efficiencies at other than full load. (2) To show that the fluxes given by curve in Fig. 1 are by no means the most economical, either from the point of view of power, loss, or economy in material in non-interpole machines, and in interpole machines fluxes of 25 per cent. or even 35 per cent. less than those given on the curve referred to are also not even the most economical for these machines. Mr. McFarlane added that he would like to ask Dr. Goldschmidt why he had not made Fig. 14 a parabola, in the same way as for the direct-current machines. As a matter of fact, it was not quite a parabola, and he should also like to say that it represented by no means the most economical curve from the point of view of the outputs of induction motors, *i.e.*, for certain fluxes he should think it would be possible to get 30 per cent. to 50 per cent. more output from an induction motor than was given in Fig. 14. Further on in the Paper the author stated : "It is well known that the power factor of an induction motor greatly depends on the leakage of the machine, this leakage being smaller the smaller the air gap, the larger the diameter and the lower the number of poles." He thought Dr. Goldschmidt must mean leakage factor there, because the leakage of an induction motor did not decrease with the decrease of the air gap; it increased with the decrease in the air gap, and it did not necessarily decrease with the larger diameter, nor did it necessarily decrease with the lower number of poles.

Mr. H. BURGE, referring to the statement that "It has to be borne in mind that the percentage copper loss increases as the square root of the number of poles," in induction motors, said this was not quite correct of the best design, because, by increasing the number of poles, the speed and the output was lowered proportionally, but the carcase being the same there was the same copper loss. They worked to a certain temperature rise, and, therefore, the percentage copper loss increased proportionally to the number of poles instead of the square root. Another point was in connection with heavy flux machines, and machines with heavy ampere wires. It was found that in comparing these two machines, although the total watts lost on the armature might be the same in each case, the machine with the heavy ampere wires would probably be about twice as hot as the machine with the heavy flux. The surface was the same on both armatures, and the total watts

Digitized by Google

were the same, yet there was this strange result. Perhaps the author could give some explanation of this.

THE PRESIDENT (Col. Crompton) said a great deal was owing to Dr. Goldschmidt, who had introduced into this country many precise methods of calculating out the proportion of flux and ampere turns, and of which he had given them the benefit in the Paper. He was in sympathy with some of the speakers in the discussion, for he could not understand how such standardisation as Dr. Goldschmidt aimed at could be obtained with complete standardisation of form, *i.e.*, length in proportion to diameter. As had been pointed out, the proportion laid down by the author would be varied a great deal if there was any change in fashion in that respect. There was no doubt that the proportion of length to diameter had, as a rule, been arrived at in certain classes of machinery from a question of economy of material, modified to some extent by the question of economics in mechanical manufacture, and it was no doubt based upon facts as they were that Dr. Goldschmidt had given his figures. But he would ask him, with all due humility, what would happen if, from mechanical or other reasons, such as convenience in manufacture, the proportion of length to diameter were varied very considerably. It could be readily understood, for instance, that for reasons introduced by Parsons in the steam turbine when large centrifugal forces had to be dealt with, the proportions of the rotating parts were varied a very great deal, and then what became of the standardisation? He was inclined to protest, although a member for years of the Engineering Standards Committee, against an attempt to standardise design or lay down hard-and-fast rules of this kind, which were only laid down on existing practice, and not on such practice as might be determined in the future. He did not make this as a "nasty" criticism on the paper, but rather that he thought Dr. Goldschmidt was a little premature in thinking it was possible to lay down hard-and-fast rules of proportion without at the same time standardising design to an extent which would, he was sure, be hurtful to the progress of the electrical industry.

DR. GOLDSCHMIDT, in reply to the discussion, said that in attempting to standardise the efficiencies and power factors, or, rather, to give figures which he thought normal, he could not start from a certain design. The majority of manufacturers designed on an expansion system. They started with a very narrow machine of a certain diameter; then they had a second type a little bit broader, and a third type still broader, so that machines for manufacturing had a great number of ratios of diameter to length, which varied about 100 per cent.; the efficiencies varied accordingly, and he could well understand that Mr. Macfarlane found discrepancies of this sort. If they drew a curve of the efficiency, it would be found to rise gradually and then jump up again. As soon as the diameter was altered, the efficiency went up more rapidly than if the width was altered, so that they did not get a uniform curve if the efficiency was plotted as a function of the power of the machine, or watts per revolution. If they drew an average curve, then they got the average efficiencies which he had given in the Paper. The greatest difficulty was not to take account of the details of particular designs. He did not want to prejudice the manufacturers in any way. But the curves were intended as a guide, although those who used them might find that for particular sizes there was a slightly lower average. They would help, also, in so far as the mechanical engineer who could not go into details of design, and who wants to know beforehand what the efficiency of his 10 h.p. motor was likely to be. He would not have obtained any results at all if he had been bothered with assuming a certain ratio of designs. He had given flux curves and curves for the ampere wires of the armature, just as an approximate idea to show how a machine was approximately built nowadays. There might be 25 per cent., or perhaps 30 per cent. less on any curve, but he was trying to show that the influence flux had on the total losses was not very great, and that it might be varied a great deal without actually affecting the total efficiency. Dr.. Thompson had asked which of the curves had been developed from actual practice, and which from first principles. All of them had been based on first principles. As a guidance he had assumed the flux curves and ampere turns curves, and then he had actually designed machines and taken machines made by other people in order not to be guided only by his own experience, and he had then got these figures, which he considered normal, for the efficiency and the power factor; therefore the curves were developed at the same time from first principles and from actual experience. Mr. Fynn stated that he thought the efficiency curves for single-phase commutator motors were rather too low. It might be possible to get a few per cent. better efficiencies by making a more liberal design. It all depended upon the temperature. They could waste material by providing more copper than was actually necessary, and so raise the efficiency, but he thought that on the average it would be found that his curves were about right; perhaps slightly on the low side. In using the curves it would be easily discovered what differences ought to be made for induction motors. Dr. Thompson had pointed out that the curves for flux and ampere wires took the form of a parabola. As a matter of fact, he had not gone into it; he had not assumed them to be parabolic, and it was quite interesting for him to hear that they were. Consequently he could not answer Mr. Macfarlane's question as to why the curve of the flux for the induction motor was not a parabola. He simply plotted the curves as normal. The flux might be 25 per cent. more or 10 per cent. less, and so on: he did not say it was the most economical flux, but it was the one which he based his calculations upon. A manufacturer, taking the flux and ampere turns curves in the Paper, could develop for himself efficiency curves, and he hoped that the Paper had been useful to manufacturers as a suggestion as to upon what lines this could be done. Mr. Fynn had pointed out that the constant for single-phase induction motors was 0·115 instead of 0·145. As a matter of fact, in the Paper he was referring to single-phase generators, the constant for which was 0·145. Mr. Fynn was right in pointing out that for single-phase induction motors the constant would be lower, and probably 0·115 would be correct. He had noted the point put by Mr. Burge, that heavy ampere wire machines were hotter than machines with low ampere wires, but did not quite know how it was meant. If Mr. Burge would tell him afterwards all about it, he would be glad to get the information and give it in his fuller reply in the *Journal*.

On the motion of the President, a vote of thanks was accorded Dr. Goldschmidt for his Paper

ELECTRICAL WINDING AT THE AXWELL PARK COLLIERY

IN the autumn of 1905 the Priestman Collieries, Ltd., owners of the Axwell Park Colliery, Durnam, decided to replace their steam-winding plant by an electrically-operated winding plant. The shaft in question is 252½ ft. deep, and is used mainly for the workmen, most of the coal being brought out through a drift. In order to avoid large fluctuations in the current taken from the supply, it was decided to adopt the well-known Ilgner system, the principle of which is to interpose between the supply mains and winding motor a motor-generator having a heavy fly-wheel capable of storing up energy during periods of light load and of delivering energy by dropping in speed during times of heavy load, and thus equalising the demand upon the supply mains. The power for operating the plant is obtained at 550 volts, 40 cycles, from the Axwell Park sub-station (about 1,000 yards from the pit mouth), which in turn is fed with three-phase current at 5,500 volts from the Carville power station of the Newcastle-on-Tyne Electric Supply Co. some nine miles distant, and from the Priestman power station about five miles away, both working in parallel. The low-tension, three phase current, after passing through the fuses and main switches, is led to the three-phase motor of the Ilgner set, and continuous current at varying voltages is obtained from the continuous-current generator of the set, and led to the winding motor, which is mounted on a common bed-plate with the winding gear, about 55 ft. above ground, directly over the shaft. The order for the complete electric winding plant was secured by the Corlett Electrical Engineering Co., Ltd., Wigan, who sublet the entire work to Messrs. Siemens Brothers' Dynamo Works, Ltd. The principal data of the winding plant are as follows:—The total maximum weight to be hoisted is 6,700 lb., the cage weighing 3,200 lb., and the men 3,500 lb. A balance weight is provided approximately equal to the weight of the cage *plus* half the weight of the men. The time allowed for a complete cycle is 55 seconds in round figures, and of this time 12 seconds are taken up for acceleration, followed by 23 seconds of full-speed run, and 5 seconds for retardation, the remaining 15 seconds being sufficient to allow the men to enter or leave. The full speed is 8 ft. per second. In Fig. 1 the line A B C D E represents the calculated output at the winding drum during the working period, while the line A F G B E denotes the requisite energy to the driving motor, the mechanical efficiency of the winding gear being taken as 88 per cent. The horizontal lines represent the

Digitized by Google

average h.p. at various points in the chain of transmission taken over a complete cycle. Although it is not possible to level out the peaks in such a manner that the energy taken from the supply is absolutely steady, yet the Ilgner flywheel converter will achieve this to a degree which meets all practical purposes.

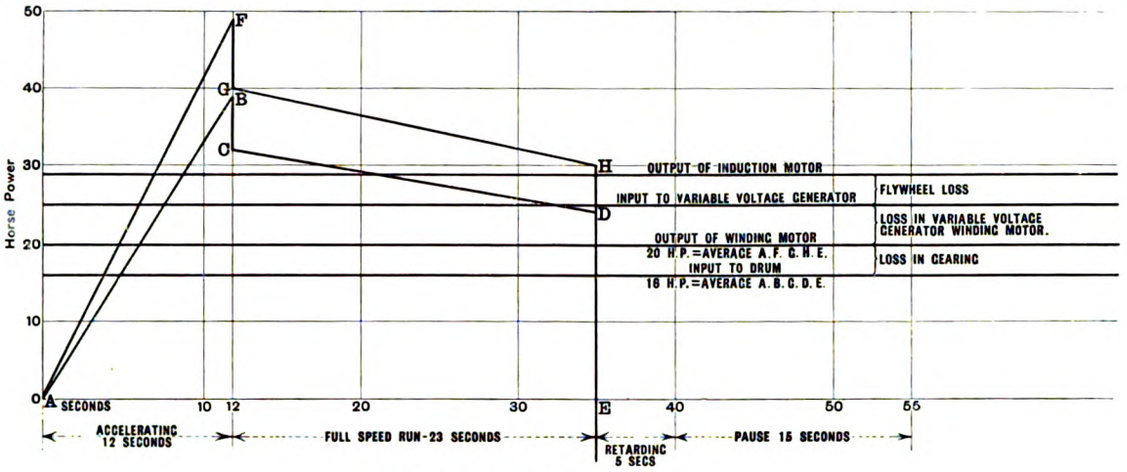

FIG. 1.—INPUT AND OUTPUT CURVES.

The Ilgner converter set consists, as shown in Fig. 2, of a three-phase motor on one side of the flywheel, and a continuous-current motor mounted on the other side. In the present instance a small exciter is also coupled to the set. This does not form an integral part of the converter system, however, and might as well be separately driven. The three machines are all coupled together and mounted on a common bedplate. The speed of the set is indicated by a tachometer, belt-driven from the coupling between the induction motor and exciter. The particulars of the various machines of the set are as follows:—The three-phase, four-pole motor is of the induction type, and provided with slip-ring rotor. Its normal output is 30 b.h.p., and its speed 1,200 r.p.m. In order to enable the flywheel to give off a portion of its stored energy during periods when the winding motor is heavily loaded, this induction motor must obviously be reduced in speed, and, *vice versâ*, the flywheel must be speeded up again during times of light load by increasing the speed of this induction motor. The regulation of speed is obtained by a regulator, which automatically adjusts the resistance in the rotor circuit in accordance with the magnitude of the current taken from the

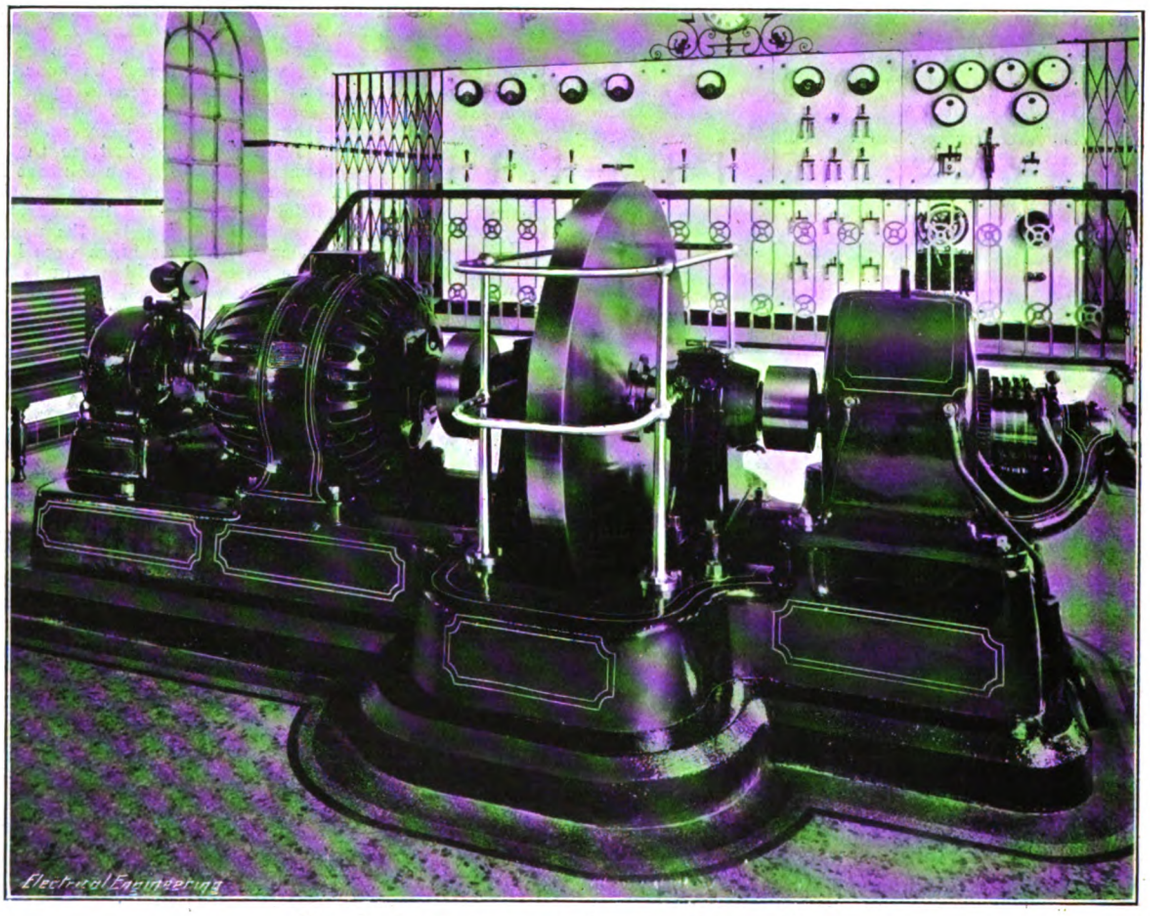

FIG. 2.—ILGNER FLYWHEEL SET FOR WINDING PLANT.

Digitized by Google

supply. To this end one of the leads to the three-phase motor is connected in series with the primary winding of a small current transformer, the secondary winding of which is connected to a relay. At normal loads, *i.e.*, at a given supply current, the tongue of the relay floats between two contacts, touching neither. When an overload occurs, however, the relay tongue abuts against one of the two contacts, and closes a local circuit through a small auxiliary motor, which now commences to drive the regulating switch in a direction corresponding to a cutting-in of resistance in the rotor circuit of the three-phase induction motor. The latter at once tends to run slower than before, and the flywheel is called upon to assist the motor by giving off part of its stored energy. On the other hand, when the current taken from the mains drops below normal value, the relay tongue touches the second contact, and the auxiliary motor drives the rheostat in the opposite direction, thus increasing the speed of the three-phase induction motor. The surplus energy beyond that necessary for the winding plant is utilised to increase the speed of the flywheel. The relay may be adjusted to keep the energy taken from the supply within any pre-determined limits. In the present instance it is so adjusted that the input to the three-phase motor varies between 28 and 38 b.h.p., the maximum drop in the speed of the flywheel being 15 per cent. below normal. It may be mentioned that the automatic regulator is combined with the starter, the design being such that the first contacts are used for starting by hand, while the other contacts are for the speed regulation of the three-phase induction motor, as described above.

The flywheel is of the plain disc type of forged steel, 4 ft. 6 in. diameter, and turned true all over with slightly-rounded corners. It weighs 2,800 lb., the radius of gyration being 1·57 ft. It is essential that the flywheel be of the best material and most accurately machined and balanced, and the steel has a tensile strength exceeding 40 tons per square inch. In order to ensure perfect freedom of running, the flywheel is supported by a pedestal bearing at each side with spherical seats. The bearings are of ample dimensions and ring-lubricated. As indicated in Fig. 2, the three-phase induction motor is coupled to the flywheel by a flexible coupling. At the slipring end the three-phase motor is connected by a flexible coupling to a 2-kw., 240-volt exciter, which supplies the exciting current to the winding motor as well as to the continuous-current generator of the Ilgner set. The latter is mounted on the side of the flywheel away from the three-phase motor. It is fitted with commutation poles, and is capable of supplying current from a maximum positive voltage through zero to a maximum negative voltage by means of shunt regulation. For this two reversing field regulators are supplied, one placed in the cage, and the other near the top of the shaft. Only one is used at a time, however, and in order to avoid mistakes, only one handle is provided, which cannot be taken off unless the controller is in the "off" position.

The reversing shunt regulator in the cage is electrically connected with the generator of the Ilgner set by a flexible six-core cable, each core containing a flexible conductor made up of 176/36 tinned copper wires, and capable of carrying eight amperes. Each wire is separately insulated with pure and vulcanised indiarubber, taped and compounded, and the six cores are differently coloured in order to facilitate connecting up. Each strand is wound round a flexible cord centre with a fairly short lay, so as to secure flexibility. The whole is wound with jute yarn, braided, compounded, and finally braided with steel wires; the overall diameter of this cable is 0·92 in. The cable is supported at the top of the shaft by a distribution box and other suitable supports. The current from the variable-voltage generator of the Ilgner set is conveyed to the winding motor, the speed and direction of rotation of which are solely controlled by the Ilgner set. This motor has a normal output of 50 b.h.p. at 800 r.p.m. It is mounted together with the winding gear on a common bedplate, and drives the winding drum by means of double reduction spur gearing with a total reduction of 28·8 : 1.

The depth indicator is driven by a chain of bevel gears and shafting, and is fixed in a position convenient for the attendant. Fig. 3 illustrates the winding motor and part of the drum. The steel winding cable has a diameter of about 0·95 in. Both ropes wind towards the centre of the drum during the greater part of the lift, but at the highest position of either cage or balance weight the rope is exactly vertical. The safety appliances adopted are very complete, as will be gathered from the following:—The cage suspension is of an improved type, and would bring the cage at once to a standstill in the shaft if the winding rope were to break. In order to prevent the attendant in the cage from over-running the bank, there are fixed in the shaft both at the top and bottom wooden cams, which engage with a lever fixed to the controller, so that the latter

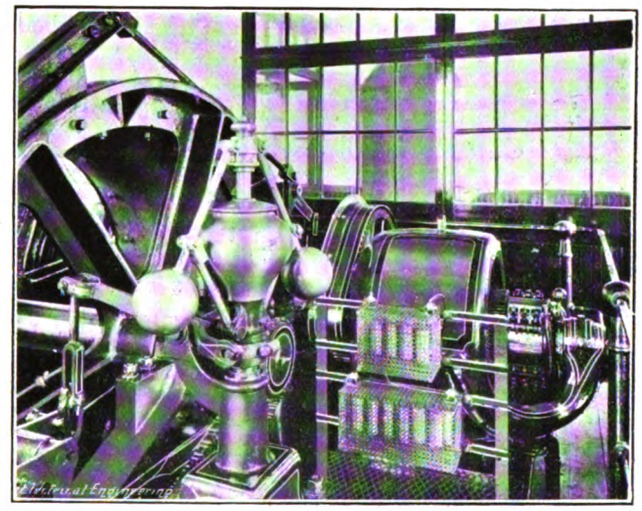

FIG. 3.—MOTOR GEARED TO WINDING DRUM.

is brought automatically to the "off" position should the cage rise higher than a few inches above the bank, or sink lower than a couple of inches below the bottom level. This arrangement, however, does not prevent the attendant from moving the cage in the proper direction. In case the cage is operated from the controller on the surface instead of the controller in the cage, it is moved to the "off" position—should the attendant neglect to do so—by a suitable mechanism engaging with cams fixed to the rotating dial of the depth indicator. These cams not only serve the above purpose, but also prevent the attendant from switching on too rapidly. In order to prevent arcing from the slow movement of the controller, a special switch of very substantial design is provided, which takes up the arc and prevents damage to the controller contacts. In order to bring the drum to a quick stop when the current is switched off from the winding motor, and to hold it in case anything occurs with the winding motor, Ilgner set, or wiring, there is an electric working brake of the post type fixed to the intermediate shaft of the winding gear. Normally, the wooden brake shoes are kept clear of the brake drum by a solenoid acting against a weight. This solenoid is energised as long as current is supplied to the winding motor, and the current to it is interrupted as soon as the controller is brought to the "off" position. The inductive kick is taken up by a suitable shunt resistance. It is obvious

Digitized by Google

that this brake will also act automatically in case the supply is interrupted due to any cause. A second brake, also of the post type, acts directly on the winding drum. It is applied by an adequate weight which is generally held up so that the brake blocks clear the drum. The weight may be tripped in two ways: It will be tripped if the winding motor should exceed its normal speed by 25 per cent., the tripping mechanism consisting essentially of a centrifugal governor driven by the motor, and the weight may also be tripped by an auxiliary tripping rope, which passes down the shaft and through the cage. In the cage there is a clamping device, by means of which the attendant can give the rope a powerful pull sufficient to release the weight of the emergency brake. In addition, this brake rope is provided at its upper and lower ends with stops which, in the case of over-winding, will come into contact with the cage, and bring the latter to a standstill by application of the emergency brake before any damage is done. A dashpot, consisting of an iron cylinder 4½ in. in diameter, with brass piston and rod, is connected to the lever of the emergency brake, and prevents a too sudden application of the brake. The switchboard, which can be seen in Fig. 2, is of marble, and the panel containing the instruments and switchgear for the electric winding plant is shown on the extreme right-hand side, the other panels being for the lighting system.

THE DEVELOPMENT OF CONTINUOUS-CURRENT TURBO-GENERATORS

Leeds Discussion

DR. R. POHL'S Paper on the development of turbo-generators, which was read in London before the Institution of Electrical Engineers on November 28th (ELECTRICAL ENGINEERING, Vol. II., page 887), was discussed before the Leeds Local Section last Thursday. It will be remembered that the Paper outlined the considerations leading to the commutation and "flash-over" limits to the output of continuous-current turbo-generators and the limiting speeds for various outputs. The possibilities of homopolar designs were also discussed, but the author did not hold out any great hope in this direction, on account of the excessive weight involved. He described a new armature winding, designed to improve the conditions in commutating machines.

Mr. WILSON HARTNELL (Leeds), in opening the discussion, remarked that the author had not referred to several limitations in the design of turbo-generators which affected the result. The high speed of such machines necessitated the reduction of the magnetic density, because the heating effect due to hysteresis was far larger than is commonly supposed to be the case. To allow for this the magnetic flux had to be reduced to less than half the amount permissible in slow speed machines. He said little about the limitation of length due to reactance voltage, nor that due to mechanical considerations. Further, he left out of consideration the compensation to be obtained by windings on the polar faces, which could be made to reduce the voltage between the segments by 20 per cent. In the speaker's opinion the suggested modification in the winding was the pith of the whole Paper. He anticipated some difficulty in design, however, as there would have to be half the number of conductors inside as there were on the outside. If this problem could be satisfactorily met, the author would have solved one of the main difficulties in the construction of D.C. turbo-generators.

Mr. A. H. LAW (Parsons & Co.) considered that, although the temperature rise from Dr. Pohl's point of view could not be considered to impose an output limit, yet it was a difficulty to be overcome. The causes of flashing over are extremely complex, but an important one is the voltage per segment. In Messrs. Parsons' earlier machines the volts per segment were 25 per cent. lower than in later machines. These early machines were tested to a maximum of 75 volts per segment, and all means were tried to induce flashing over, but without success. Faulty machines could be improved by thickening the mica insulation. Slot-wound armatures were, from some points of view, not so satisfactory as surface wound. The latter could be made quite mechanically sound, and it was easier to obtain satisfactory commutation with them. In the speaker's opinion compensating poles have their limits. The curve of ampere conductors per centimetre given represented satisfactory practice. The speeds obtained by Messrs. Parsons were in excess of those given by the author, *i.e.*, 500 kw. machine, 3,000 r.p.m.; 900 kw., 1,800 r.p.m., and 1,500 kw., 1,200 r.p.m. Homopolar machines were quite out of the question for turbo work His firm had constructed a machine for 10,000 amperes at 5 to 7 volts, but the amount of iron and copper required was enormous, also the speed was too low. He wished to compliment Dr. Pohl on the ingenious solution presented by his proposed method of winding. If this proved satisfactory in practice it would, no doubt, be largely adopted.

Mr. HARDING CHURTON, Leeds, said the Paper had led him to wonder if some of the suggestions to increase the output of turbo-generators could be applied to ordinary D.C. machines. He would like to know how the cost of turbo-dynamos compared with slow-speed machines.

Mr. W. F. MYLAN, Sheffield (Westinghouse Co.), looked upon the subject from a commercial point of view, and asked whether these alterations were going to result in cheaper machines. If not, why trouble with turbines at all? It was sufficiently difficult at present to convince customers of the advantages of turbines over slow-speed reciprocating engines. No mention had been made of the use of carbon brushes. It was essential that th brushes should wear away more rapidly than the commutator, but with metal brushes the result was often the reverse. His firm were using carbon brushes on a flat face commutator at right angles to the axis of the armature. This plan overcame all chattering due to the whip of the shaft, and machines using this design were running with perfect satisfaction. He confirmed the author's adverse opinion respecting homopolar machines. They had built a 300 kw. set and used a homopolar exciter, but had to replace it by an ordinary commutator machine.

Mr. R. HOLIDAY (Acton Hall Colliery), also considered the Paper from a commercial rather than a theoretical aspect. His experience showed there was still need for improvement in the machines for power purposes. He was afraid the new winding would introduce complications which would do away with that extreme simplicity of present turbine plants, which was their great virtue.

Dr. POHL, in replying, said that the question of temperature limit came in for a finished machine, but not for a machine which had to be designed, as it was then possible to provide suitable means to keep it cool. He did not think that two-pole machines would survive, but that multipolar designs with six or eight poles would become the rule. Multipolar machines for turbines were much cheaper for a given output, just as they were with slow-speed machines. A turbo-generator for, say, 1,000 kw., was about 50 per cent. higher in cost than a slow-speed machine for the same output. The reactance voltage increased with the armature length, but the principal limitation in length of armature was the flash over limit. He did not like the plan of preventing flashing by increasing the width of the mica, as this weakened the commutator, and shortened the time of commutation, consequently increasing the reactance voltage. What was gained in one respect was lost in another. Referring to the various criticisms touching his suggested winding, he said there would be no difficulty with respect to the internal conductors, as they would only have to carry current during the period of commutation, and could be made relatively much smaller, also there would be no mechanical difficulty in accommodating them. Referring to Mr. Mylan's question, the commercial advantage of improving turbo-generators was in being able to reduce the size of the machines, consequently the cost would also be less.

Helion Filament Lamps.—According to the *Electrical World* (New York), three American patents were issued January 14th to Mr. W. G. Clark on processes for making incandescent lamp filaments of the type consisting of a combination of silicon and carbon. The deposits of silicon have been obtained by the decomposition of chlorides, and the object of the patent is to obviate the difficulty that has been experienced in getting a uniform product and to prevent the chlorine once free from combining with the silicon. The first patent describes a process wherein a carbon filament is placed into a receiver containing a small quantity of mercury, after which a silicon chloride, such as a tetra-chloride, and also a gas which contains carbon are introduced. When the current is passed through the filament the chloride is decomposed and the silicon deposited upon the carbon, and the free chloride combines with the mercury. The second patent covers the use of the carbon gas referred to above, the claims being for the mixture of marsh gas and an olefiant gas, or marsh gas, olefiant gas and carbon dioxide. The third patent states that the hydrocarbon gas may be some form of illuminating gas, but is preferably the marsh gas. When the deposition on the filament takes place the silicon and combination of silicon and carbon, which is a dense, non-porous combination, enter the pores of the carbon base, combine with and build up on the base, so that the latter becomes a combination of silicon and carbon, which gradually merges near the surface into a substance having characteristics similar to those of silicon.

COST OF ELECTRICAL POWER FOR INDUSTRIAL PURPOSES

THE following is a report of the discussion on Mr. J. F. C. Snell's Paper in Glasgow on January 14th. For a report of the Paper itself, and the discussions in London and Dublin, reference should be made to ELECTRICAL ENGINEERING of January 16th and 23rd. The latter issue also contains several written communications of considerable interest, and some further ones are appended in this article.

DISCUSSION IN GLASGOW.

The CHAIRMAN (Prof. F. G. BAILY) invited Mr. Robert Robertson to open the debate.

Mr. ROBERT ROBERTSON, although he found little to take exception to in the general conclusions, thought that all the bases upon which the prices were given were too low, particularly in the case of the Tables Nos. I. and II. The author had pointed out that the examples of actual plants which he quoted were, in most cases, higher than these tables, but the difference between them was so enormous that it could not be passed over merely by a simple remark. The diagram below was made out practically in the same form as that shown in the Paper on Fig. 2, having the ordinates representing the cost per unit, and abcissæ, &c., representing the load factor. Two of the curves represent the figures given in Tables I. and II. of the Paper as the ascertained cost of power per unit generated for independent plants, in the one case for installation up to 100 horse-power, and in the other case for installations from 100 to 500 horse-power. The dotted line marked "interest" has been calculated on the basis that the cost of the station per kilowatt of maximum demand is taken at £25, a figure which might be taken to agree with certain concrete cases. The points *A*, *B*, *C*, &c., represent the actual figures cited in the Paper for certain plants that had been tested. Thus, *A* shows the cost obtained in the first shipyard mentioned (ELECTRICAL ENGINEERING, January 16th, p. 74). Although considerably greater than the corresponding figure in Table II., the cost agrees with those in the table for the smaller-sized plants; but the proportion of it representing interest and depreciation, shown in the diagram by the point A_1, is considerably less than half what it should be if the cost of the plant was something like the average that assumed of £25 per kw. The point marked *B* represents the next example given—a

combined shipyard and engine-works—and with this 1,000 horse-power the cost was enormously greater than the 100 to 500 horse-power in the Table. The next example, shown by the point *C*, is also for a plant of 1,000 horse-power, and the cost of it lies between the cost of the small plants and the cost of the 100 to 500 h.p. The point *D*, represents an example taken from Mr. Williamson's Paper, read before the Institution of Electrical Engineers in 1903, in which a 640 kw. plant, costing £20·5 per kw., was run at a cost of 0·716*d*. per unit, with a load factor of 37. The cost was again very much higher than in the table for plants up to 500 h.p. Point *E* is for the paper mill mentioned by the author, with 79 per cent. load factor. It relates to steam-driven plant, not to an independent electric generating station, and from the difficulty of arriving at the average amount consumed by steam engines, the speaker thought it was very difficult to accept figures of that sort. He had had a case recently of a plant with a power very much like this, where he was informed that the engine was practically running at six days a week, which would give a load factor of something like 80 per cent. It was electrified, when it was found that the load factor was only 50 per cent. Point *F* is a jute mill, mentioned in the Paper. It is slightly under the 500 h.p. cost in Table II., although the power was over 900 h.p. The points A_1, B_1, C_1, &c., on the diagram indicate the proportion of costs applicable to interest and depreciation in the examples *A*, *B*, *C*, &c. From these examples, it was evident that with smaller plants the cost in reality should be very much greater than that given in the tables, and in many cases of small installations up to 400 or 500 h.p., if everything was taken into account, he was doubtful whether the actual cost, within the limits of 10 and 50 per cent. load factor, would come much under the line marked XY, which came down to 0·8 at 50 per cent. load factor; interest and depreciation are allowed for in this curve. He had several figures that closely approximated to that line. Mr. Robertson next discussed the cost at which power companies or power suppliers could supply. The figures indicated by the author were based upon a total cost of £25 per kilowatt, but no electricity works of any size supplying power in this country had been erected to approximate to that price. The only example cited by the author was the Newcastle Power Company, whose capital cost was given at £59 per kw. The most reasonable method of charging for supply was, he thought, making a charge of so much per kilowatt per annum, with the addition of a small amount per unit. The figure at which companies could supply, he thought, might be taken as £4 per annum per kilowatt and from 0·5d. down to as low as 0·2d. per unit.

The first and third chain-dotted lines in the diagram indicate these charges as they work out for different load factors, and between them is a dotted line indicating the figures given by the author as the real cost (given in column 4 of Table XIV.) of the Newcastle Company based on the 1906 figures. There were a great many other points in the paper that one might go into in detail, but it would only be, so far as he was concerned, in most cases to concur generally with the author. He had examined the costs of sub-stations, and whilst he thought the prices were taken rather on the low side, the difference between them and real costs which he had recently incurred was not so great as to warrant taking much exception to them. In dealing with the limit of distance to which a supply company could distribute current, they had to deal with a question of average. If a company went a distance of 20 miles, it also had probably a much larger proportion of consumers, if the situation of the station was well designed, within a very short radius, and it depended on the density as to the distance that might be gone economically, taking the supply as a whole. If each individual case was first taken, then, of course, it would be necessary to differentiate in charge between consumers near the generating station and consumers far away. That, he thought, was not a reasonable ground for differentiation in charge, because it was not the fault of the consumer, but the fault of the situation of the generating station, and the differentiation between charges among consumers should be based upon the different value of these consumers' operations to the supply.

Mr. C. P. SPARKS dealt to some extent with the same points to which he alluded in the London meeting reported in our last issue. He also referred to Table VI. of the Paper, in which the cost of a power-house and transmission were given at £13 and £12 respectively. A £12 transmission scheme was unknown in this country and in the world, and at the moment only existed on paper. At Newcastle the cost was £26, and there they would find great difficulty in dividing it by two. If Mr. Snell would tell them how to do it, he would welcome him as a pioneer. On the other hand, he thought that municipalities could supply very much below the figures set forth in Table IX. Some of them took several years before they brought the tariff down, so that business passed them. If they looked at it from the point of view of the additional capital necessary to deal with the additional load, they could, at all events in some cases, supply this at half the figure, and make a profit.

Mr. LACKIE (Engineer-in-Chief, Glasgow Electricity Works), after complimenting Mr. Snell on his Paper, and expressing gratification that Mr. Snell himself was present, gave, as an example of the fallacy of thinking only of the load factor, the case of electric hoists. The load factor of an ordinary hoist motor in the city was under 9 per cent., but, by all the hoist motors getting their supply from one source, the supply authority was enabled to give the hoists energy at a rate per unit corresponding to at least a 20 per cent. load factor. The same reasoning must apply to the industrial user, and therefore it appeared to him that a maximum price for electrical energy for power or industrial purposes might be fixed at a price corresponding to 20 or 25 per cent. load factor, and the price thereafter should be made to meet a better load factor than 20 or 25 per cent. Those 10 per cent. load-factor users could not generate power at a rate to compete with a 20 per cent. load factor if all considerations were taken into account. He would not take up the time of the meeting elaborating the points with which he agreed, but would rather confine himself to a few notes on matters regarding which he was inclined to differ. He maintained that the supply from a town installation

Digitized by Google

or power company should be cheaper and better than the private user could hope to do with his own plant, if all considerations were taken into account. The "critical" load factor and size of plant within which any outside supply could hope to compete against the user's own local plant was not fixed, as Mr. Snell seemed to convey in his second axiom, but depended entirely on the size of the outside supply plant. Mr. Snell had also stated that many electricity undertakings were supplying power at less than cost price; he must emphatically state that in Glasgow they were not doing that. In Tables I. and II. the outstanding fact was that the cost of steam was less in every case than the cost of suction or producer-gas plant. That was contrary to all the data that had been put before him. Where was the 10 horse-power for a penny man with his suction-gas plant? The example given of a gas plant in a shipyard, which had also been referred to by Mr. Robert Robertson, had apparently a serious error in its capital cost. It was stated that interest and depreciation would amount to £60 for four months, or £180 for a year, so that the capital cost of the plant would be £1,800, or £8 2s. per kilowatt. He was perfectly certain that that plant was never put down for £8 2s. per kilowatt, and in support of that would point out that in every other case stated by the author the cost ran between £15 and £20 per kilowatt. It was also stated that the gas consumption in this plant was 36 cubic feet per kilowatt-hour—a large figure even on so low an annual load factor as 14 per cent. He was of opinion that the annual load factor had nothing whatever to do with the gas consumption, but only the plant load factor; and the fact that the plant load factor was 48 per cent. (a very good percentage), the only conclusion that one could come to was that 36 cubic feet per kilowatt was about the average figure that one got with gas engine plant instead of the figure of 15 to 20 cubic feet quoted by gas engine makers. It really amounted to this, that the cost of gas per unit with gas at 2s. 4d. per 1,000 cubic feet was about a penny. In all the examples stated, of course, Mr. Snell had not allowed for land and buildings or rent, rates and taxes. Mr. Snell had estimated a colliery load factor as about 36 per cent., and the annual load factor of a steel works and other similar works at about 20 to 25 per cent. But it must not be forgotten that with a public supply they were able to offer a consumer having an annual load factor of 20 to 25 per cent., a rate corresponding to a load factor of about 40 per cent., owing to the fact that some of the plant which was used during the day to supply the day consumer was also used during the night for supplying some night consumers. Mr. Snell stated that the modern power station of important magnitude and favourably situated could be now equipped completely for £12 or £13 per kilowatt installed. That did not agree with the modern power station of Carville (which he spoke of later on), where the capital cost was £59·6 per kilowatt, and it was of interest to note that the Newcastle charges with their capital cost of £59·6 per kilowatt compared favourably with the theoretical London County Council figures, with an alleged capital cost of only £25 per kilowatt. The horse-power of motors installed in a factory had generally a diversity factor of about 2, and the result of an individual diversity factor of 2 divided amongst all the consumers gave a diversity factor on the station of about 3. In tramway supply the diversity factor was about 10, *i.e.*, for every 100 kw. of motors, only 10 kw. of maximum demand was made upon the power house. Hoists had about the same diversity factor as a tramway supply, and each trade had its own diversity factor. Probably the worse the load factor, the greater the diversity factor. In his recommendation of alternating current supply through static transformers, the speaker continued, Mr. Snell had not mentioned the effect of these transformers on his power factor, nor the wattless current and the loss in cables. Further, if, as advocated, works having 100 kw. or more each had their own local static sub-station, that would add tremendously to the cost per kilowatt, and the cost quoted would be probably doubled. After boldly stating that many London companies were selling energy under cost price for power purposes, Mr. Snell had added: "This means that the power user is being supplied by these undertakings at the expense of their lighting consumers, who are paying an unduly high rate for their supply, or, in the case of certain London municipalities, at too high a cost of public lighting." If it was not for these power consumers in Glasgow, at least, the coal consumption would be about 7 lb. per unit, whereas to-day it was under 4 lb. If it was not for that sale of current for power purposes, they would require something like a farthing per unit more for lighting to make up for the difference in coal consumption. Mr. Snell did not indicate in any way whatever how he arrived at the correct charge to be made by the London local authorities and larger municipalities, and he must state that he did not at all agree with the figures he had given for Glasgow. In Tables IX. the "mean" column simply represented the mean of the five figures given in the five columns. Now, the probability was that in Manchester there were ten times the units consumed that there were in Nottingham, and, consequently, to get the true mean one would require to take the number of units sold at 5d. and the number sold at 4·9d. in Nottingham, and similarly with Leeds and Glasgow, and so get the true mean or average. The conclusion of Mr. Snell's paper was a most unfair one. He stated that, looking back, it would have been much wiser if the authorities, viz., the Local Government Board and Board of Trade, had prevented some of its smaller local burghs from adopting separate electricity stations. He did not agree with that statement at all, for if the Local Government Board and Board of Trade had not allowed the smaller local burghs to do so, a company would have stepped in and done the work, and the companies would be in no better position to-day than those small local burghs. Further, those local burghs had done pioneer work and given a supply while the demand for electrical energy was growing and the public being educated to its use. Would a power company ever have erected a large works in the vicinity of those burghs if the burghs had not first shown that there was a demand and profit to be made from the supply of electrical energy? Some people might think that the Corporation of Glasgow should have started away with a station such as they now have at Port Dundas. If they had, he did not for a moment believe that their revenue would have been more than it was for the first three or four years with their Waterloo Street Station, and if that had been the case the revenue would not have paid interest and sinking fund on the lands and buildings and machinery put down. The undertaking would further have been put down as a financial failure, and would have acted as a stumbling block to other electrical undertakings. He was afraid also that the remedy Mr. Snell suggested would not prove a beneficial one to the power companies, although it was quite correct. Those smaller local burghs would only call upon the power companies to supply their peak load in the winter months, and instead of a load factor of 30 or 40 per cent., it would be more like 2 or 3 per cent. for some years to come.

Mr. J. ROBERTSON (Engineer-in-Chief, Greenock) said that the shipyard load factor was a very bad one, owing partly to the class of tools, and partly because of fluctuations in trade that they did not get in an ordinary factory. It was because of that that the public supply came in. If they took half a dozen works of that kind and supplied them from a public station, it followed that the supply from a public station would be less than the individual plants in private generating stations, and for that reason the public supply had an advantage. There was a curious likeness between the figures relating to shipyards supplied by Mr. Snell and the figures at Greenock. He thought he was altogether too pessimistic, however, in his views regarding the future of municipal stations in this country. At the station at Greenock, which had been in existence for nine years, the capital expenditure came out at £43 per kilowatt. The figure of £70 which was put down as the average cost per kilowatt included such stations as Liverpool, Bradford, Leeds, and Birmingham, where large sums had been paid to companies in order to buy them out. Moreover, Mr. Snell did not take account of the fact that in a great many of the instances of these stations that they had been in operation for a considerable time, and had already paid back a large proportion of their original capital. He thought, apart from the supply of power to big users, there was still plenty of hope for the small and medium-sized station. The lighting load had been the backbone of most of the stations in the country. Although the units generated might show a large balance in favour of power, they generally found that on the revenue side of the balance sheet the biggest income was still from the lighting customer.

The discussion was then adjourned until the next meeting of the section, when Mr. Snell has promised to be present to reply.

Additional written communications have been received to those published in our last issue.

Mr. J. H. BOWDEN (Chief Electrical Engineer, Poplar Borough Council), in his letter, added to the censure already passed on Mr. Snell's Table VII. When this table in its complete form was laid before the Parliamentary Committee last year, he had understood it simply as a means to an end in engineering the L.C.C. Bill through the Parliamentary Committee, and that it should not be taken seriously. He compared Mr. Snell's figures for Poplar with his own:—

Mr. Snell's statement:—

Actual charge, 1·43d. Correct charge, 1·68d.
Probable charge for direct current by Power Company, 0·83d.

Mr. Bowden's figures:—

	1906.	1907.	1908.*
Actual charge by Poplar.	1·389	1·156	1·12
Load factor of system ...	22·84	24·26	23·5
Power units sold	1,379,620	2,423,538	3,500,000
Net profit	£600	£635	£3,340

* Based on actual balance sheet to Dec. 31, 1907, and estimated to March 31st, 1908.

"I am accredited," writes Mr. Bowden, indignantly, "with charging the sum of 1·45d. per unit for something which ought to be charged at 1·686d., but which might be obtained elsewhere for 0·85d." Referring once more to Table VII., Mr. Bowden again objects to the figure 0·83d. per unit as misleading, as it represents what would be charged to authorised distributors under last year's L.C.C. Bill, not to consumers who might be charged 1·254d. per unit for low pressure direct current, which is more than the average charge for power at Poplar to-day. Mr.

Digitized by Google

Bowden then gives figures to show that Mr. Snell's scheme would be no more economical to Poplar than their own extensions. He also finds fault with his Tables VI., which, he says, are worked out upon the capital cost per kilowatt installed, whereas they should be based upon the capital cost per kilowatt of maximum demand. By this alteration he raises Mr. Snell's figure of £29·73 per kw. to something in the nature of £50.

Mr. W. B. ESSON writes that Mr. Snell had arrived at practically the same conclusions as he himself had done in an address on "The Industrial Power Problem" to the Civil and Mechanical Engineers' Society in October, 1906. He had then estimated the cost of electrical power for a factory which could be served by an engine of 500 b.h.p. It was assumed that the generator would give 350 kw. maximum, and would supply 750,000 units per annum, this corresponding to a load factor of about 25 per cent. The cost of the fuel was put in at rates somewhat different from Mr. Snell's, but the total cost, taking 10 per cent. as the interest on capital outlay and depreciation, was given as follows :—

	Mond gas.	Suction gas.	Steam condensing.	Steam non-condensing.	Oil.
Total cost per unit	0·516d.	0·564d.	0·513d.	0·536d.	0·592d.

He also agrees with Mr. Snell's remarks as to prices charged by existing supply stations, and has no doubt that for a big increase in the amount of power supplied by the companies at the same rates, it would be found that the total receipts are not commensurate with the total costs.

The British Correspondence School of Electrical Engineering.—Several attempts have been made from time to time to establish institutions for giving a technical training by correspondence. In those originating on the other side of the Atlantic, we are afraid that there has been somewhat of a tendency to undertake impossibilities, and to create an impression in the mind of the untrained aspirant to electrical knowledge that a few magic correspondence lessons will immediately put him in a position to make an income several times as great as that he is already earning. Leaving extremes on one side, however, there is quite a considerable legitimate field for such enterprises, provided that the information imparted is carefully chosen in relation to the capabilities of the pupil. We do not consider that correspondence tuition can ever be as satisfactory as more direct instruction, but there are vast numbers of cases where it is a question of this class of teaching or none, and here the opportunity comes in. In starting a British Correspondence School of Electrical Engineering, Messrs. Broadbent and Andrew Stewart are providing facilities of this nature, and, so far as we can gather from a glance at one or two sample "lessons" forming part of one of their practical engineering courses, the information imparted is just of the practical nature required, while it is sufficiently detailed to escape the imputation of providing only the "little knowledge" which is apt to be a "dangerous thing." The questions which the student has to answer in particular appear well chosen from the point of view of stimulating thought as well as testing the result of the instruction.

The Manchester Electrical Exhibition.—The Organising Committee with reference to the forthcoming Electrical Exhibition at Manchester is now complete. A meeting was held on January 20th at the Town Hall, Manchester, when Councillor Kay, J.P., of Manchester, was elected Chairman of the Committee, and Councillor Barrett, J.P., of Salford, Deputy Chairman. The Secretary gave a full report of the scheme as existing up-to-date, and it was unanimously decided to put same into effect, and to enter into the necessary arrangements for holding the Exhibition in Manchester next October. In order that matters should be dealt with promptly, an Executive Committee was appointed, consisting of the following gentlemen :—The Chairman, the Deputy-Chairman, the consulting engineers, Messrs. Pearce & McCowan, Messrs. H. Berry, H. Bevis, D. N. Dunlop, F. Nalder, C. D. Taite, H. Talbot, and a meeting of this Committee was held at the offices of the Exhibition, 2 Queen Anne's Gate, Westminster, London, on Monday last, when arrangements were considered with reference to the site of the Exhibition, necessary buildings, &c., &c. In order that the Committee may be able to decide definitely as to the size of the buildings which it is immediately necessary to place the contract for, it is intended to send out a preliminary circular to the trade, asking for an indication as to space required by various exhibitors, and the design of the buildings will be such that extensions can readily be effected up to within three months of the date of opening. Large numbers of applications have already been received from the principal electrical and engineering firms throughout the country, and it is hoped that all those likely to be interested will assist the Committee in concluding their final arrangements by dealing with the matter promptly, and by getting in touch with the management at the earliest possible moment. The Executive Committee have been instructed to enter into agreements with Messrs. Northcote & Davenport for the carrying out of their requirements.

RAILWAY ELECTRIFICATION

AT the Royal Institution on Saturday last, Prof. G. Kapp delivered his second lecture on the electrification of railways. A report of the first lecture will be found on page 113 of our last week's issue. The lecturer pointed out that, as a result of the lead taken by American engineers in continuous-current electrification, all the railways in England on that system, with one exception (the Liverpool-Southport line, equipped by Dick, Kerr & Co.), had been electrified by American engineers.

Some years ago Continental engineers had realised that the continuous-current system would not satisfy the requirements of main-line working, and had given that attention to alternating-current systems.

A recent improvement in the continuous-current system is the application of commutating poles to the motors, thereby increasing the output and the safe working pressure per motor. The motors used on the Cologne-Bonn and Moselhütte railways (ELECTRICAL ENGINEERING, Vol. II., p. 639) are examples of 1,000-volt interpole motors. Another improvement is the use of gearless motors, as on the locomotives of the New York Central Railway, where the armatures of the two-pole motors are mounted direct upon the axles, and the field system is part of the body of the locomotive. For main lines, a high trolley-wire pressure is essential, and, to use this in conjunction with continuous current motors, Krizik has devised the following system : Two trolley-wires are used, one of which has a pressure of 15,000 volts above, the other 15,000 volts below, earth. The rails are used as the neutral conductor, but only at starting. When running, four motors are in series across the two trolley wires; the voltage per motor is thus 750 volts. At starting, the four motors are in series between one trolley wire and the rails; the voltage per motor is then 375 volts. The motors are geared in pairs to ensure that the pressure is equally divided. Prof. Kapp was of opinion that an ordinary three-wire system, as in use on the City and South London Railway, would not be suitable for main-line working, as the load would not be sufficiently balanced.

Particulars were given of several English railways, mentioning in particular the system of buffer battery stations on the Liverpool-Southport line for equalising the load on the generating station.

In passing on to three-phase working, the lecturer pointed out that the Burgdorf-Thun railway, electrified nine years ago on the three-phase system, had been a marked success. The fixed speeds were not such a drawback as had been expected, and lost time could be made up on a down grade by inserting resistances in the rotor circuits of the motors and running considerably above the synchronous speed. On the Valtellina Railway, measurements extending through the whole month of October showed that the energy consumption was only 80 watt-hours per ton mile; this included transmission and trolley-wire loss, as well as heating and lighting.

For single-phase working, the direct use of alternating current with compensated series or repulsion motors had superseded the Ward Leonard converter system. A few remarks were added on the methods to be adopted on the London, Brighton, & South Coast Railway, where motors of the Winter Eichberg repulsion type will be used.

Wireless Telegraphy in the Caribbean.—The De Forest Wireless Telegraph Company are erecting wireless telegraph stations at Belize, Puerto Barrios, Puerto Cortez, Cebia, and probably at Port Limon, and Costa Rica. The operations between these places and the United States are to be completed by the first week in February. The installations are being erected for the United Fruit Company, U.S.A., but they will be open to public service.

Liverpool and the New Telephone Tariff.—The question has arisen in Liverpool as to whether the new telephone tariff can be enforced there, as it seems that in an agreement entered into between the Liverpool Corporation and the National Telephone Company in 1896, there is a clause which is as follows :—"Clause 13.—The scale of charges for telephonic service at present applied to the Liverpool Central Telephonic Exchange of the company shall not be increased beyond the present amounts as set out in the schedule hereto, and such scale, subject to any reduction that may be made as hereinafter mentioned, shall be equal in its application throughout the city, and every citizen of Liverpool prepared to pay the charge and to sign the company's usual form of agreement for an exchange line shall have the right to demand telephonic service to his premises in Liverpool, and the service to be provided in pursuance to such demand shall be constant and continuous." This clause appears to be very clear on the subject, and it seems as if the subscribers of Liverpool are protected from the new tariff, and this agreement will bind the Post Office authorities when they take over the telephone systems.

THE HEAT CONDUCTIVITY OF IRON STAMPINGS

Birmingham Discussion

A SHORT discussion followed the reading of Mr. T. M. Barlow's Paper read on January 15th before a meeting of the Birmingham Local Section of the Institution of Electrical Engineers. Mr. Barlow himself was prevented by illness from being present. We gave a lengthy abstract of the Paper in our last issue (page 121). In it the author gave the results of a series of experiments on the heat conductivity of assembled insulated iron stampings both in directions parallel and at right angles to their surface. The results emphasised the importance in dynamo design of the amount of edge surface of the stampings of a laminated iron core exposed to a cooling medium. The most efficient ratio of the linear dimensions of the edge side to the plate side was given as 1 : 10, a much higher ratio than commonly in use.

Dr. W. E. SUMPNER (Birmingham Municipal Technical School) said that the author was to be congratulated on his Paper. The apparatus used was very well designed, the experiments had been well carried out, and the results obtained should prove valuable. He criticised the mathematics used in the Paper, describing it as vague. He then referred to the constant C^2. It was stated in the Paper that C^2 was the ratio of conductivity along the stampings to the conductivity across the stampings. This formula was quite true if the temperature gradient was the same in each direction. Inside the core the heat flow is quickest in the direction of the greatest gradient. On the outside surface, however, a unit of area dissipates equally whether it is edge-on or face-on. The temperature excess of the outside surface over the air was therefore different for different portions of the surface, and the ratio of which he spoke depended consequently upon shape and dimensions. The discrepancy referred to near the end of the Paper could be explained in this way.

Mr. LINDSAY FORSTER (Messrs. Chance Bros., Birmingham) asked the author whether the heat did actually come out of the stampings as assumed in the Paper. Were the wood ends which were used in connection with the testing apparatus sufficient insulation against heat leakage? He knew an example of design in which the cooling of the armature iron was effected solely by edge conductivity.

Mr. D. K. MORRIS (Coventry) said it was remarkable how long designers had been content to do without such important information as that contained in the Paper. Although the Paper and particularly the mathematics might be criticised, still, the results obtained were broadly correct, and should prove useful to the designer. He objected to the statement that the iron loss increased with the rise of temperature. Losses due to both hysteresis and eddy currents decreased with increase of temperature.

Prof. KAPP then explained that the increased loss referred to by Mr. Morris was a secondary effect arising from a change in the flux distribution as explained in the Paper.

Prof. G. KAPP said that he did not intend to reply to the discussion, but there were a few remarks he would like to make. First, as to how the investigation came about. Some time ago, at his suggestion, the committee of the German Institution of Electrical Engineers had voted a sum of money to Prof. Linde to carry out experiments on the subject. In these experiments, which were done on packets of plates and paper, one face was heated with hot water and the other cooled with melting ice, a number of precautions being taken the necessity for which had been pointed out by Mr. Forster. The work had been in progress two years, and as a preliminary result Prof. Linde had given the value of the constant C^2 as 80. But this result had not been confirmed, so he had suggested to Mr. Barlow that he should investigate the subject, using an apparatus which would approach more nearly to standard conditions. A question raised by the Paper was—Is the flat surface of a packet of stampings of any real value? In order to get a clearer idea, he had worked out the value of the combined or total surface in terms of the edge surface for different shapes of packets.

Ratio $\frac{\text{flat surface}}{\text{edge surface}}$ =	1.	2.	3.	4.	5.	7.	10.
Factor expressing value of total surface ... ... =	1·01	1·04	1·09	1·16	1·25	1·5	2·0

In practice it was customary to make packets about seven times as long as thick. Theoretically this should be 10, but such a ratio would lead to waste of room, so that seven was not a bad compromise. In reference to Mr. Forster's remarks, it was quite possible that the wood ends used with the apparatus did not entirely prevent the flow of heat, but in any case the flow of heat was all right on the medium line. He had no doubt that the experiments were substantially correct. Mr. Barlow's figure for C^2 was 100, as compared with Prof. Linde's 80. The difference was probably due to the amount of end compression on the stampings.

Telephonic Developments in Sweden.—On Friday the Swedish Government introduced a Bill providing for a loan of five million kroner (£278,000) for the development of the telephone service.

The Euston-Watford Electric Railway.—In reply to a communication from the Watford Urban District Council, the London and North-Western Railway Company state that owing to the unfavourable state of the Money Market at the present time, they do not feel justified in attempting to raise the large capital which will be required for the construction of the electric railway between Euston and Watford. It will be remembered this line received Parliamentary sanction last session, and will run partly in tube and partly on the surface.

Bournemouth and Poole Corporations and Poole and District Electric Traction Co.—On Thursday, in the Court of Appeal, before the Master of the Rolls, Lord Justice Fletcher-Moulton, and Lord Justice Buckley, the hearing was commenced of an appeal by the defendants in the action brought by the Corporations of Bournemouth and Poole against the Poole District Electric Traction Co., Ltd. The appeal was brought from a judgment of Mr. Justice Joyce, the case being heard before him in the Chancery Division (see ELECTRICAL ENGINEERING, Vol. II., p. 623). This case arose out of the claims made by the Corporation of Bournemouth, when taking over the Poole and District tramways from the company. The claims were for outstanding amounts, viz., the sum of £7,000 in respect of a loan from the London & South Western Bank, and £4,558 in respect of liabilities from sundry creditors. These amounts were afterwards reduced by accountancy to £6,476, and £2,570, which his Lordship held the company were entitled to. It was stated that the question arose as to whether Mr. Justice Joyce had rightly decided that the company was to pay to the corporations three sums on deposit of £1,875, which required to be paid under the Light Railways Act, and which was returnable when the line was opened for traffic, a sum of £544 9s. 4d., due for sundry debts to the company, and a sum of £1,410 cash in hand, and at the bankers. The company, said counsel, was formed to construct a light railway between Bournemouth and Poole in 1899, and it subsequently acquired an extension order and powers to construct another tramway to Christchurch. They also had running powers over the Bournemouth Corporation tramways. The Bournemouth Corporation also had sundry tramway undertakings, and they had powers to construct another line, in respect of which they had to commence within a year of the date of the order. It was alleged by the company that they had not done so, and an action was brought to restrain them from carrying the order out. Mr. Justice Joyce found in favour of the Corporation, but his decision was reversed on appeal. The Corporation intended to appeal to the House of Lords, but the litigation was comprised in an agreement for the sale of the company's enterprises in Bournemouth to the Corporation, and it was in respect of this agreement that the present dispute arose. The Corporation was to pay £5,500 in cash, and a sum, which was fixed by the arbitrator at £100,000 as being the fair market value of the undertaking as a going concern. Mr. Justice Joyce had decided that the Corporation was, in addition, entitled to the three sums he had mentioned, but the appellants contended that they did not form part of the undertaking as defined in the agreement. Mr. Hughes, K.C., appearing for the Corporation, supported the judgment of Mr. Justice Joyce, and contended that the three sums were all included in the valuation of £100,000, which the corporation had paid. There was also a cross-appeal by the Bournemouth Corporation in respect of two sums of £6,476 odd out of a bank loan of £7,000, and £2,570 for sundry creditors, which the judge below had allowed to the company. Judgment was delivered on Friday, when the Master of the Rolls said the deposit had been returned to the depositors before the date appointed for the transfer of the undertaking, and he found nothing which gave the Corporation any claim to it. He found, if possible, still less ground for the second item for sums due for sundry debtors to the company, because it was really an accountant's mode of apportioning sums which had been paid over a period partly extending beyond the appointed day. Every word he had said with regard to the deposit applied with equal force to the third item of cash in hand and balance at the bank, and it was only part of the company's undertaking that was purchased, and there was no ground for the suggestion that any part of the cash in hand was acquired by the Corporation. As to the second appeal, the Corporation had undertaken to indemnify the company in regard to liabilities or engagements outstanding on the appointed day, and he saw no ground whatever for limiting it as the Corporation proposed. Lord Justice Fletcher-Moulton and Lord Justice Buckley agreed, and the company's appeal was therefore allowed, and the Corporation's appeal dismissed with costs.

CATALOGUES AND PAMPHLETS RECEIVED

COLLIERY CABLES.—Messrs. W. T. Glover & Co., Ltd., have sent us a copy of a reprint of a Paper read by Mr. G. G. L. Preece some time back before the Institution of Mining Engineers on recent improvements in the design of electric cables for collieries, in which two forms of cable developed by Messrs. W. T. Glover & Co. specially for mining work are described. The feature of the first of these cables is what is known as the patent solid strand filling, and consists of the filling of the interstices between the wires composing the strand with a solid compound which will not run or become displaced by the heating of the conductor through overload. In course of manufacture the central wire and each succeeding layer of the stranded conductor is covered with a thin tube of plastic bituminous compound. This compound being thoroughly worked into the irterstices of the strand, all capillary passages for moisture are stopped—in fact, water cannot be forced in even under pressure. The second cable described is called "the patent solid three-core bitumen-cable." The mode of manufacture is as follows:—The conductors of this cable are each separately insulated with bitumen compound; they are then laid together round a shaped central core of bitumen which fills up the central space; and the whole is sheathed over with a solid tube of bitumen, which is forced on so as to be ribbed internally and to fit exactly the interstices between the three cores (Figs. 1, 2, and 3). The cable can then be taped and protected by armouring as desired. Among the advantages claimed are, higher dielectric strength, greater chemical protection against bad water, &c., better mechanical protection of the cores, and special suitability for use as a shaft cable in a vertical position. Messrs. Glover ask us to state that they will be glad to send a copy of the pamphlet to anyone interested.

FLEXIBLE METALLIC TUBING.—A price list is to hand of various forms of flexible metallic tubing, manufactured by Ch. Rudolph, of Paris. Rubber and asbestos packed tubing, with and without steel plaiting, is included, with several patterns of unions and connections. A special non-air-tight covering for cables and wires is listed. The London office is at 11 Queen Victoria Street.

PETROL AND PARAFFIN ENGINES.—We have received from Messrs. Bolton & Paul, of Norwich, a price list of vertical cylinder petrol and paraffin engines, suitable for coupling directly to dynamos and pumps. The sizes listed range from 1¼ to 5/ b.h.p., the latter of which engines has eight small cylinders, and runs at 800 r.p.m. A useful feature of the list is the addition of particulars as to the time of delivery of each size. Illustrations of engines applied to various purposes are given.

TELEPHONES.—The General Electric Co.'s new telephone catalogue reaches us just as we go to press. It is an excellent production, and the company has brought out several new types of instrument and alterations in their standard designs. A feature that we particularly notice is that the cases of a large number of instruments have been modified so that the terminals are protected and out of sight. We hope to publish a fuller notice in our next issue.

TRACTION SPECIALITIES.—New leaflets are being issued by the Consolidated Accessories, Ltd., of some tramway appliances of Messrs. G. W. Green & Co., for which the company are agents. These include the devices manufactured under the patents of Mr. P. J. Pringle (Borough Electrical Engineer, Burton-on-Trent), namely, a two-blade rail cleaner, a trolley tension indicator, which is an apparatus fixed to a special car which is lifted by the trolley wheel as it passes and causes different signal lamps to light up according as the pressure is within a certain range, and a trolley standard earthing device for indicating when a trolley standard becomes alive and providing means of removal of the earth connection for the car to be taken back to the depôt.

TUBULAR FUSES.—Among the new leaflets issued by Messrs. A. Reyrolle & Co., Ltd., is one dealing with L. T. tubular fuses for use in distributing panels or boxes. In these fuses, which are listed up to 600 amperes for voltages not exceeding 600 volts, there are two tubes, one surrounding the fuse wire and the other between the first tube and the porcelain handle, so that thorough ventilation is provided.

LETTER OPENER.—We have received from Electrical Installations, Ltd., a well-made and useful letter opener.

American Tribute to Lord Kelvin.—At a meeting at the Engineering Societies' Building, New York, a series of what are described as "Memorial Exercises," were held on Sunday, January 12th, in honour of the late Lord Kelvin. The ceremony was under the direct auspices of the American Institute of Electrical Engineers, but several other engineering organisations participated. The observances included prayers and an address by Rev. W. T. Manning, D.D., and Mr. H. G. Stott (president of the Institute). Prof. Elihu Thomson and Prof. E. L. Nichols spoke of Lord Kelvin's scientific and electrical engineering work, and Mr. G. G. Ward and Admiral G. W. Melrose referred to his position with regard to submarine telegraphy and navigation. The friendly relations between the great man and the American Institute were mentioned by Mr. T. C. Martin. Music of a suitable character was performed during the meeting, and the programme contained a sonnet written by Prof. W. M. Stine.

THE AIR-GAP CORRECTION CO-EFFICIENT

AN original communication by Mr. P. H. Powell has been selected by the Institution of Electrical Engineers for publication in a forthcoming number of the *Journal*. The communication is supplementary to a paper by the same author published in 1905 in Vol. 34 of the *Journal*, page 21, and contains a short account of some experiments in continuation of an investigation of the air gap correction co-efficient. In the earlier Paper open slots were dealt with, whereas the second investigation was devoted to partially closed slots. The experiments were conducted on the stream-line method, and a number of photographs of the stream-lines obtained with sectional models of teeth of various proportions were taken, from the measurements of which the corresponding values of the required co-efficient were deduced for 28 different cases given, values varying from 1·062 to 1·320. The chief factors determining the co-efficient are the length of air-gap and the width of slot opening. The rounding of the corners is unimportant, as also is the width of iron in the lip of the slot, provided this width is above a certain limit. The ratio of the width of slot to width of tooth is of some importance. A few typical examples of the stream-line photographs are reproduced in the Paper, from which it can be seen that only a very small proportion of the lines manage to keep in the slot; this is very marked in comparison with some of the diagrams in the previous Paper for open slots. As might be expected, the disturbing effect of the presence of the teeth on the distribution along the pole-face and in the pole shoe becomes more and more marked as the gap decreases. A number of tables and curves are given showing how the co-efficient varies with different values of the ratios of the dimensions.

Moscow Tramways.—It is stated that the municipality intend to issue a loan of £187,000 in connection with the construction of the existing tramway system to electric traction, the contract for which has been granted to a British syndicate.

New Zealand Tariff.—In the memorandum on the recently adopted new tariff of New Zealand, published by the Tariff Commission itself, it is to be noted that British electrical machinery is admitted free of duty.

The Junior Institution of Engineers.—At the last meeting of this Institution, a Paper on "The Conduit System of Electric Tramway Construction and Recent Improvements" was read by Mr. Fitz Roy Roose, of the L.C.C. Engineers' Department. The salient features of the original line from Westminster to Tooting were briefly described, and the differences between them and the present system of construction were dwelt upon at length. The extended yokes which were now used, besides carrying the slot rails, formed anchors to which the track rails were fixed at intervals of 7 ft. 6 in., and would be found of great advantage when renewals of track rails had to be carried out. A cast-iron plate now formed the cover to the insulator pockets, instead of cast-iron boxes as previously, which, as they became worn by traffic, had to be replaced, and were also the cause of a great deal of dirt getting into the conduit. Drainage, insulators, cable connectors, &c., were dealt with, and special work at crossovers and junctions, and insertion of junctions during reconstruction were referred to. The side slot system was touched upon, as also the electrical supply to the line. A description was given of the plough or collector, and in conclusion the following figures were cited as the cost per mile (single) of the respective systems, including special work as pipe diversions, &c.:—Conduit, £17,000; surface contact, £9,700; overhead, £9,200. On the following Saturday afternoon, by permission of Mr. Maurice FitzMaurice, Chief Engineer to the London County Council, an inspection was made of the reconstruction work in progress in Stockwell Road. The method of forming the concrete conduit by means of the improved sheet-iron centring, the process of inserting the copper connecting pieces between the lengths of conductor bars, with the insertion of the insulators and manner of carrying out other special work was demonstrated. The members afterwards proceeded by one of the latest types of cars to the sheds at Clapham High Street. The car was run into the shed on to the electric traverser, and moved thereon to illustrate the method of bringing the cars into their place in the depôt. The Motor School, where the drivers are instructed in the manipulation and operation of the controllers, brakes, &c., was then shown, much interest being manifested in the skeleton stationary and working car. All the leads, &c., for traction and lighting being visible, the men can be readily taught how the various connections are made. The sub-station was also seen, containing three motor generators (a fourth is now being erected). Delivered at a pressure of 6,600 volts from the generating station at Greenwich, the three-phase alternating current is transferred to 550 volts continuous for use on the lines. About five miles of double track are fed from the sub-station.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

IN the January number of the *Electrochemical and Metallurgical Industry* there is an interesting account of the Electric Induction Furnace used for the refining of steel in the Roechling iron and steel works at Voelklingen, Germany (compare ELECTRICAL ENGINEERING, Vol. I., p. 852). With the furnace now in use it is possible to make a very soft, medium, or hard steel, starting with steel from a basic lined converter. The steel is supplied to the electric furnace in the molten condition, and can be decarburised, deoxidised, and recarburised. The particular feature of the Roechling-Rodenhauser furnace which distinguishes it from the Colby-Kjellin design is that it combines two methods of electric heating. The first is the ordinary heating by means of electric induction currents; the second kind of heating is also with induction currents, but these are introduced into the molten bath through metal plates, termed electrodes. The second form has some similarity to heating with ordinary alternating currents. The furnace is designed for a 5-ton charge, to be operated at 5,000 volts with a frequency of 15 periods per second. The furnace is shown in Figs. 1 and 2. It is essentially a transformer with a single primary winding *A* round both iron cores *H* of the transformer. There

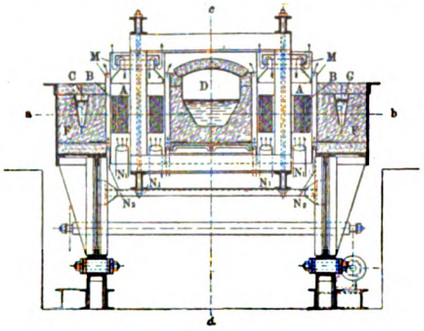

FIG. 1.

are two secondaries, one being the molten bath, which is in the form of an ∞, the channel *D*, in which the metal is smelted and which is situated between the two cores, being very broad. The other secondary is the copper winding *B*, which is connected with the metal plates *E* (Fig. 2). These metal plates are inserted into the furnace walls *F*, so that the currents pass from the windings *B* through the plates *E*, and through the refractory electrolytic conductors to the molten mass *D*. These electrolytic conductors are on the principle of the Nernst filaments. The molten mass *D* is thus subjected to the heat of the direct induction currents, and also to that of the electrolytic conductors.

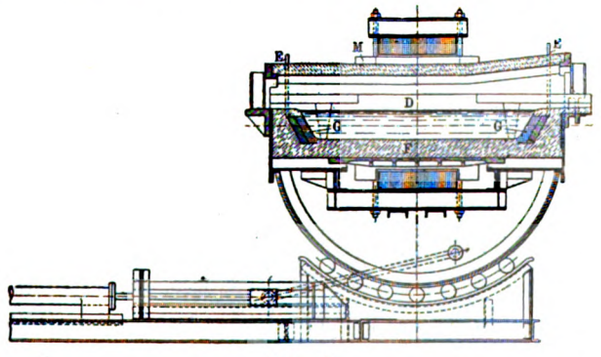

FIG. 2.

The windings are protected against the high temperature by thin walled copper canals *M M*, through which a blast of air is passed, being expelled at *N*, *N*; the transformer iron is also ventilated by means of slits. The charging door is at one end of the furnace, the tapping door at the other. When in operation sufficient circulation takes place to dispense with all manual agitation, it only being necessary to see to the correct formation of the slag and to tap it off. Fig. 2 shows that the furnace can be tilted, and in general design it is not unlike the Siemens-Martin open-hearth furnace. The normal charge is from 3 to 3½ tons, but about 15½ cwt. are left in the furnace at the end of each operation, so that the new charge only consists of from 2½ to 2¾ tons. The reason for leaving some metal in at the end of the operation is to keep the furnace hot. The method of procedure in starting is to first provide a basic lining of magnesia containing 10 to 12 per cent. of tar, after which the inside of the furnace is strongly heated. For this purpose rings of soft steel are placed in the furnace, and are heated to from 900 to 950° C. by induction currents. As soon as smoke ceases to be given off from the volatilisation of the tar, fluid pig iron is introduced from the blast furnace. The electric circuit is then closed, and the temperature commences to rise. At the end of 18 hours the furnace is at full heat.

All except 15 cwt. of the pig iron is then tilted out, and steel from the basic converter is introduced. Burnt lime containing about 6 per cent. of magnesia is placed on the surface of the molten metal, and about 18 lb. of fluor-spar, to get a sufficiently fluid slag. The refining now commences; if the slag becomes too fluid lime is added, if too thick, fluor-spar. The first operation is finished when bubbles no longer rise up through the molten mass. The slag is removed and a pure lime slag added, and ferro-silicon to deoxidise. If high-carbon steel is required, then powdered coke is also added. For ordinary steels Spiegeleisen is added as usual.

In order to make hard steel free from sulphur, the steel must be left for a longer time in the furnace, and the sulphur must be removed by oxidation, or by addition of manganese and a slag.

Compared with converter steel, the electric steel runs exceedingly smoothly when cast, this being due to the very high temperature of the molten metal. With the electric furnace it is possible to remove completely all impurities from the steel. Two men are sufficient to work the furnace, a third being required to attend to the electrical equipment. The power factor is satisfactory. At 2,600 volts with 145 amp. the kilowatts were 330. The power factor—cosine of the phase difference between E.M.F. and current—was 0·875. The cost of refining for a 5-ton furnace for one ton of soft steel is 24s. 6d.

The final conclusions of Prof. Wedding, who reported upon the process, are :—That the furnace serves simply for refining. It enables the last impurities to be removed, and the introduction of any desired amount of carbon or other elements. It is a substitute for the crucible process, and has not the disadvantage of absorbing silicon from the crucible walls; further, there are no deleterious gases. The process appears to be economical on a large scale.

In the *Engineering Supplement of the Times* of Jan. 22nd there is an article upon the manufacture of calcium nitrate and calcium cyanamide. Mention is made of the increase of the Notodden works already noticed in our columns (ELECTRICAL ENGINEERING, Vol. III., p. 57). The bulk of the article, however, is devoted to a description of the various works erected or about to be erected in connection with the manufacture of cyanamide by the Frank and Caro process (ELECTRICAL ENGINEERING, Vol. I., p. 223 and 613). Owing to the success which attended the original installation at Piano d'Orta, in Central Italy, which was erected in 1905, other plants have been erected. In France the Société Française des Produits Azotes has been formed, and works are nearly completed at Nôtre Dame de Briançon, in Savoy, which will have an annual capacity of 3,750 tons of cyanamide. In Switzerland a company has been formed, and works are being erected at Martigny, on the Rhone above Geneva. In this country the North-Western Cyanamide Co., of London, are erecting a large factory at Odde, upon the Hardanger Fiord in Norway.

The power for the company is generated by an independent company, the power-house being located higher up the Fiord, 11 kilometres from the cyanamide works. The water is brought by means of a tunnel 4 km. in length to a point on the cliff, above the generating station, where an effective head of 1,350 ft. is obtained. The present installation is designed for an output of 20,000 h.p., but four times this amount can be obtained if required. It is hoped that the works will be in operation by March, 1908. The carbide for making cyanamide is to be obtained from the Alby United Carbide Factories, Ltd., which have their works at Odde.

In Germany the Bavarian Government have granted a concession to the Cyanid Gesellschaft of Berlin to utilise the waters of the River Alz at Trostberg. It is expected to obtain about 15,000 h.p.

At Mühltal (Bromberg), in Posen, the Brandenburgische Carbidwerke are producing 2,500 tons annually of cyanamide under a licence from the Italian company. The Gesellschaft für Stickstofferdungen are also producing cyanamide at Westerglen by a rival process. The American Cyanamide Co. is also referred to (ELECTRICAL ENGINEERING, Vol. II., p. 144).

The cyanamide is being sold at 1s. to 1s. 6d. per unit of combined nitrogen cheaper than ammonium sulphate, and from 3s. to 3s. 6d. per unit cheaper than nitrate of soda. The price is thus about £10 10s. per ton, and unless there is a large turnover it can hardly be remunerative, seeing that it is made from calcium carbide which cost rather more than £8 per ton.

New Wireless Telegraphy Station at Paris.—A Reuter's Paris telegram states that the Minister of War is approaching the Municipality of Paris with a view to purchasing a piece of land on the Champ de Mars, near the Eiffel Tower, on which to build a new wireless telegraphy station. It is stated that the new apparatus will make wireless communication between Paris and New York possible.

ELECTRICAL SCIENCE

British and American

Relation of Mass to Energy.—In the January *Philosophical Magazine*, D. F. Comstock investigates mathematically the motion of a system of electric charges. The charges, which may be single electrons, are supposed to obey the condition that they maintain the same, or nearly the same, distances from one another. He finds that the total momentum of any isolated, moving, purely electrical system is

$$2W_T \Big/ \left\{1 + \left(\frac{v}{V}\right)^2\right\} V^2,$$

where W_T is the energy arising from those components of the electric and magnetic fields which are perpendicular to the velocity v of the moving system, and V is the velocity of light. From this expression, if v/V be small, the author deduces that the mass, due to the motion of the electric system, is $4W/3V^2$, where W is the total electrical and magnetic energy of the system, and V is the velocity of light. This agrees with the well-known expression for the electro-magnetic mass of a charged conducting sphere moving slowly, and also with Searle's more elaborate formula. The former is obtained at once from the present author's formula by putting $W = \frac{1}{2}$ (charge × potential). The formula shows that the electro-magnetic mass of a system is proportional to the electro-magnetic energy, which is, on the corpuscular theory of matter, the internal energy of the atom. If this is true, the loss of internal energy occurring in material transformations should involve a diminution in mass. The diminution in mass following an ordinary chemical change is calculated by the author to be too small to be detected by experiment. In radioactive changes the alteration of energy is much greater, and the loss of mass by the whole system is large enough to be detected. On the disintegration theory of the elements this loss of mass affords a ready explanation of the small irregularities in the tables of atomic weights; and it should be noticed that it is not necessary for the whole energy of the atom to be electro-magnetic for this loss of mass to take place. The author points out that his theory that mass is proportional to internal energy indicates that gravitational attraction is an action between quantities of energy, and he computes on this basis that the weight of a caloric at the surface of the earth is of the order 10^{-11} dyne.

Continental

Undamped Electric Oscillations.—There are ways of producing steady electric oscillations apart from Poulsen's arc. One of these is described by O. M. Corbino in *L'Elettricista* for December, p. 329. It consists in coupling a series dynamo with a shunt motor, and does not require a condenser. The principle underlying the system is put as follows:—"A shunt motor, having field magnets and armatures of laminated iron, when subjected to an alternating sine p.d. at the terminals, behaves as an inductive resistance, whose inductance may have a negative value. Hence such an apparatus is equivalent to an inductance connected in series with a capacity. For a certain value of the speed, the inductance and the capacity are independent of the frequency." At this speed, therefore, the impressed p.d. need no longer be sinusoidal. A dynamo is equivalent to an inductance and a negative resistance as far as the period of the entire system is concerned. The author gives formulæ expressing the inductance, capacity, and resistance of the whole combination, and shows that the damping is, under suitable conditions, automatically compensated.

Dielectric Constant of Tysonite.—The fluoride of rare earths known as Colorado tysonite shows the magnetic displacement of absorption bands very clearly. These bands are greatly sharpened in liquid air, and the magnetic displacement in opposite directions, which at ordinary temperatures merely amounts to a broadening, develops a doublet at a temperature of −188° C. But the sharpening of the bands is not purely a matter of absence of damping. J. Becquerel shows, in *Bulletin* No. 270 of the French Physical Society, that there is a decided increase in the dielectric constant at the lower temperature, whose most striking manifestation is a fivefold increase in the magnetic rotatory dispersion. More energy is absorbed, more of the molecules being apparently capable of absorbing it. The rotatory dispersion appears to be entirely due to the simultaneous effect of anomalous dispersion and the separation of bands into two components corresponding to opposite circular orbits of electrons. The total number of absorbing electrons is $3{\cdot}54 \times 10^{13}$ per c.c. in xenotime at 20°, and $5{\cdot}96 \times 10^{13}$ at −188° C. It is just possible, the author remarks, that every electron absorbs energy, and that its charge is about a billion times smaller than hitherto assumed. But that, he admits, is exceedingly improbable.

Spectra of Alkali Metals.—The new series of lines discovered by Bergmann in the infra-red spectra of potassium, rubidium, and cæsium is attracting a good deal of attention among spectroscopists and those interested in the intimate anatomy of the elements. C. Runge manages to allocate to the new series a proper place among the three series already known. The new series bears the same relation to the first sub-series as the principal series does to the second sub-series. All the series are known to crowd up to definite limiting frequencies called "terminators." Subtracting the terminator of the new series from that of the second sub-series, we get the frequency of the first pair of lines of the first sub-series. The terminators of the new series are: Potassium, 13482·4, rubidium, 14344·4, and cæsium, 16848·8. In cæsium all the line pairs are equidistant on the scale of frequency. In the other metals the pairs are too close to pronounce on this point. In all three cases, the principal terminator is higher than either of the terminators of the first and second sub-series. The new terminator, on the other hand, is lower than either. There is, in fact, a kind of mirror symmetry between the four series.

Electron Theory of Magnetism.—In their attempts to formulate a theory of magnetism in accordance with modern views of electricity, both Thompson and Voigt encountered the difficulty that there must be a resistance to the translation of electrons in orbital rotation. By considering the effect of electro-magnetic induction upon revolving electrons, Langevin overcame this difficulty, and arrived at a theory which agreed with all the phenomena observed in diamagnetic and paramagnetic bodies. Weiss has recently extended this theory to ferro-magnetic bodies. An important contribution to a fuller theory has now been made by Z. Thullie, who bases his calculations upon the general assumptions of Voigt, but supposes that the magnetic field impressed upon the substance is generated within a time which is of the order of magnitude of a single revolution of an electron round its positive atom. This allows of a much more accurate investigation, and closely touches magneto-optic phenomena. The final result of the somewhat elaborate mathematical investigation is a complete vindication of Langevin's theory. Diamagnetism is a fundamental property of all matter, and Weber's and Ampere's molecular currents are best represented by electrons in orbital motion.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Jan. 23rd, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1906 Patents

27,358. W. P. HAMLYN. This specification describes an automatic electric circuit-breaker, of the free handle type. The circuit-breaker is operated by means of a toggle, which forms in the closing and closed positions of the circuit-breaker a collapsible closed polygon, not forming a part of the toggle device. The latter is prevented from collapse to allow the circuit-breaker to open independently of the position of the closing switch, by a catch controlled by the automatic tripping gear of the circuit-breaker. The operating mechanism is in the form of a collapsible closed triangle, of which the contact arm forms one of the sides in combination with the toggle for actuating the contact area and cramping it in the closed position under control of an automatically-operated catch. Three claims, three figures.

1907 Patents

98, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*, New York.) This is a method for direct-current electric transmission systems of the high-tension type, and its object is to provide a system of this character, having advantages not hitherto attained. The invention consists of employing unipolar generators connected in series for producing the high voltage

Digitized by Google

required, and providing means for keeping a constant line voltage for varying loads. The employment of unipolar generators avoids the necessity of a constant current transmission, as there is no commutator at which a flash-over might occur during variation of the current or a short circuit of the line, a self-excited shunt field can be provided with any desired fraction of the total voltage of the machine by connecting the field winding to the collector rings. The generator may be arranged so as to maintain a line voltage which is constant, or slightly increasing as the load increases, but will drop the voltage rapidly when the load increases above the output of the station. Five claims, two figures.

155, THE BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*, New York.) A new method of sealing the lamp filaments to the leading in wires of metallic-filament lamps. Filaments, of refractory metals, alloys, or compounds, have operating temperatures considerably higher than that of the ordinary type of carbon-filament, so that the usual method of attachment is not practicable with metallic filaments. The metallic filament is welded directly to the lead wire, by melting the end of the lead wire into a compact globule within which the filament is enclosed. The fusing or welding operation is carried on in a protective atmosphere by electricity. The means of performing this consists of a glass jar, to the bottom of which is secured a standard, provided with a clip for holding the stem of a lamp in a horizontal position. A small tube extends downward to the bottom of the glass jar, and serves as a means of conducting carbon dioxide or other inert gas into the jar, to act as a protective medium during the sealing operation. A second tube of copper or other material extends down into the jar, and then bends up in a semi-circle, and is provided with small openings so disposed that when the gas is supplied to these tubes it will impinge on the ends of the leading in wires. Two electrodes, one of copper and the other of carbon, are attached to the jar. Each of the leading in wires is bent in the form of a hook, and one end of the tungsten, and when the current is switched on the two metals fuse together. Three claims, three figures.

521, E. PEARCE & S. WALTON. Is an improvement in inclined carbon arc lamps, and particularly those in which two sets of carbons are used, and is to obviate the chances of the carbons overfeeding and sticking. The usual type of weighted carbon holders to feed the carbons are used, regulated by a series and shunt solenoid acting through a rocking lever, controlling the rotation of a pulley around which cords pass to the carbon holders. The improvement consists in mounting fast upon the pulley spindle a large and small ratchet wheel. The smaller ratchet wheel engages with a pawl mounted on the pulley, so that the movement of the pulley in relation to the ratchet wheel is in one direction only, namely, that in which the carbons are wound up. Engaging in the teeth of the main ratchet wheel is a double toothed rocking pawl pivoted on any suitable part of the frame. This double pawl is acted on by a spring, so as normally to take up a position in which one of its teeth engages the main ratchet wheel, and the movement of this double pawl is effected by the rocking arm worked by the solenoids. Thus the ratchet wheel is only allowed to move relative to the length of carbon consumed, and the carbons are prevented from feeding too freely by the restraining influence of the small ratchet wheel. Four claims, two figures.

4,363, THE BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*, New York.) A new substance for insulating electric conductors, providing a means by which a conductor may be coated with a thin, tough, elastic, firm adherent film, which has high dielectric properties and is waterproof, infusible at all temperatures, non-inflammable, does not crack or scale off when the wire is bent, even in curves of small radii. The process consists of previously thickening a quantity of vegetable oil, such as linseed by the application of heat, and dissolving the residuum in a solvent, and the thickening is provided by mixing a quantity of linseed oil with 2 per cent. of oxide of zinc, and a similar quantity of oxide of lead. The mixed mass is heated to a temperature of 500°–600° F., and this is continued until the oxide is entirely taken up by the oil, and the required degree of dissolution is effected. When the mass has reached a suitable stiffness, 25 per cent. of rosin oil is added, and the mass allowed to cool. The film is hardened by the application of heat; a coating of a non-drying material is then applied. Three claims.

4,802, V. POULSEN. This relates to improvements in signalling in wireless telegraphy, and the object is to signal in such a manner that the vibrations in a circuit of the transmitting apparatus are periodically damped, which is accomplished through the operating key, by inserting in the vibration circuit or in parallel with it a device for damping the vibrations, so that the vibrations of the circuit connected to the antenna can be damped as required. The arc is placed in an atmosphere containing hydrogen. The vibration circuit may be closed directly by means of an operating key, so that the ohmic resistance is short-circuited. If the circuit is opened by the operating key the vibrations are damped by the ohmic resistance, and the system ceases to transmit waves. Three claims, three figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

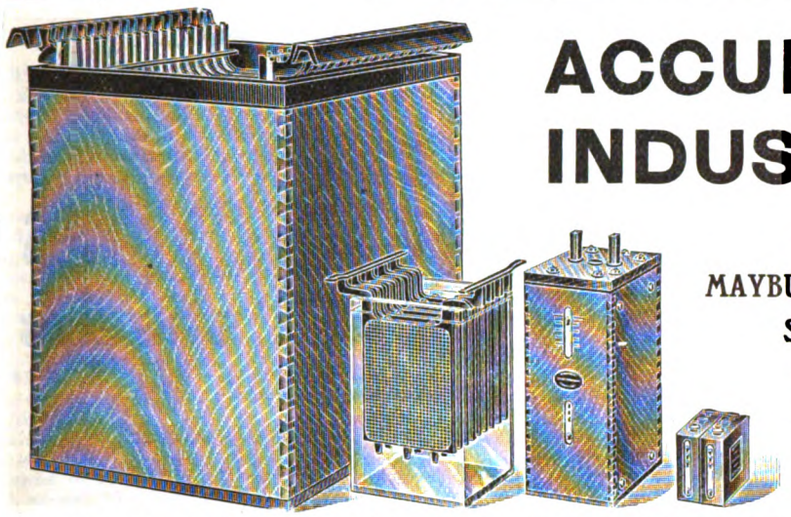
24,582, BRUCE, PEEBLES, & CO., & LA COUR. Phase transformers specially applicable for transforming single-phase electric currents to polyphase electric currents, or *vice versa*.
27,445, PARSONS & BALL. Electrical contact making and breaking devices.

1907 Patents

298, RAVENSHAW, MIDDLETON, & TOWNSEND. Magnetic clutches and brakes.
523, GODDIN. Electro-capillary apparatus.
2,595, ATELIERS THOMSON-HOUSTON. Dynamo-electric machines.
3,927, COUADE. Electric motors.
3,996, ELECTRIC IGNITION CO. & HALL. Magneto-electric ignition apparatus for internal-combustion engines.
4,429, COUADE. Synchronous operation of phonographs and kinematographs by electric motors.
5,751, MACKENZIE (*Ludwig Bolle & Co*). Electric melting furnace.
6,133, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Signalling systems for railways and the like.
7,141, ALBRECHT. Dynamo-electric differential driving gear more especially intended for motor road vehicles.
7,408, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric locomotives.
8,287, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Lightning arresters.
9,515, BULLERS, LTD., & CHAMBERS. Insulators for telegraph poles and the like.
9,516, THOMAS. Combined door latch and electrical alarm.
10,597, TAYLOR. Apparatus for automatically operating electric switches for starting and stopping electrically driven pumps.
11,621, BROOKS & AKERS. Means for operating alternating-current machines in parallel.
11,828, SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*). Transformers for use in making electrical measurements.
12,932, BRITISH WESTINGHOUSE ELECTRIC AND MANUFACTURING CO. (*Westinghouse Electric and Manufacturing Co.*). Means for preventing inductive disturbances in telephone and other electrical transmission circuits.
13,940, FORSTER. Trolley-pole holders for electric railways.
14,838, SIEMENS BROS. DYNAMO WORKS, Ltd. (*Siemens-Schuckertwedke Ges.*). Compounding of alternate-current dynamo-electric machines.
15,453, LATOUR. Single-phase electric motors.
16,618, ALLGEMEINE ELEKTRICITÄTS-GES. Transformers and controlling apparatus therefor.
18,319, GIRDLESTONE & JONES. Apparatus for automatically limiting an electric current to a predetermined value.
18,955, ARTOM. Transmitters for electro-magnetic waves.
19,829, GILMORE. Process of manufacturing reflector incandescent lamps.
20,651, HARTENSTEIN. Carbon holders for electric furnaces.
21,030, MÄRKISCHE MASCHINENBAUANSTALT LUDWIG STUCKENHOLZ AKT.-GES. Magnets for lifting.
22,301, NOEGGERATH. Current-collecting devices for dynamo-electric machines.
23,497, SIEMENS-SCHUCKERTWERKE GES. Spring support for an electric motor arranged on the axle of a vehicle.

Complete Specifications open to Public Inspection before Acceptance, under the Patents Act, 1901.

1907 Patents



24,288, BOSCH. Contact breakers for electrical ignition in internal-combustion engines.
26,762, SCHÄFFER. Transforming machine for operating arc-lamps and incandescent lamp-circuits of low voltage.
27,926, ALLGEMEINE ELEKTRICITÄTS-GES. Apparatus for welding rings, hoops, chain-links, and the like, by means of an electric current.
28,427, ALLGEMEINE ELEKTRICITÄTS-GES. Electric measuring instruments.
28,542, HIORTH. Electric induction furnace.
28,634, LAMME & STORER. Electric locomotives.

1908 Patents

66, LITTLE. Arc lamp electrodes.
324, CHRISTIAN. Electrically-heated hot-water bottles.

LOCAL NOTES

BRENTFORD: *London United Tramways Co.'s Bill.*—Brentford District Council has decided to offer no opposition to the London United Tramway Co.'s Bill, now before Parliament, for the construction of tramways over Kew Bridge, to connect the Middlesex system of the company with the line from Kew to Richmond. Opposition to the Bill has, however, been lodged by the Middlesex County Council, which, with the Surrey Council, controls the bridge and its approaches.

BRIGHOUSE: *The Electricity Supply.*—At the monthly meeting of the Brighouse Town Council, held on the 22nd inst., it was decided to purchase for £800 a plot of land with a frontage to the Huddersfield Road, on which to build a sub-station in connection with the Yorkshire Electric Power Co., and to purchase electricity from that company, and distribute the same throughout the district.

BRISTOL: *New Tramway Regulations.*—The Board of Trade has issued new regulations for the Bristol tramway system. The regulations comprise all the equipment, which is required for braking, &c., which is in force in other towns, but they also enforce each car to carry a speed indicator, and no trailers are allowed to be attached to the cars. The speed of the cars must not exceed 16 miles an hour at certain places, and four miles an hour at all facing points and round all curves.

CARDIFF: *Tramway Track Repairs.*—It is estimated that the repairs which are necessary on the tramway track will cost £100,000. The track is reported to be in very bad condition, which has been caused by the sinking of the rails, due to faulty foundations. The wearing out of the rails is due to the system of running four-wheel cars, which rock very badly in some places.

CHISWICK: *The Noisy Tramcars.*—The District Council has contributed £50 towards the costs of the action proposed to be instituted in the name of the Ealing Town Council against the Tramways Co., for an injunction in respect of the alleged nuisance caused by the noise of the tramcars by reason of the defective track and the defective machinery of the cars.

DUNFERMLINE: *The Electricity Undertaking.*—Sir Alex. Kennedy, who was invited to give expert opinion on the electricity undertaking of the Dunfermline Town Council, has issued his report, dealing elaborately with the whole question. He advises the Council to transfer their Provisional Order to the Fife Power Company.

EXETER: *Electricity Returns.*—The Electric Lighting Committee states that the results of the nine months' working of the electricity undertaking to December 23rd shows an improvement in all departments over those of the corresponding period of 1906. The total revenue has increased by 16 per cent., and the total units only 14 per cent., due to economy in distribution. The generating costs had only increased 7 per cent., although the price of coal had increased 20 per cent. The increase in gross profits for the nine months was £800 over the corresponding period of the previous year.

FINCHLEY: *Electricity Bulk Supply.*—The North Metropolitan Electric Supply Co. are considering the tariff of the supply in bulk of electricity to the Finchley Council.

FIFE: *Mining Fatality.*—At the Frances Pit, Dysart Collieries, Alexander Coombs, a miner, was nailing a piece of corrugated iron on the box covering the electric cables, when the nail pierced the cable, and the shock instantly killed him.

GREYSTONES: *Electricity Scheme.*—It is proposed to form a small company to undertake the provision of a power station and the electric lighting of the town. The scheme comprises the use of suction-gas plant and gas engines to drive the generators. The contractors, Messrs. Coates & Son, Ltd., are providing part capital, of which the total for the whole undertaking is not to exceed £3,000. It is estimated that 34,000 units per annum will be generated, and the proposal is to sell at 6d. per unit.

HANLEY: *Electricity Reports.*—The monthly reports for October and November, 1907, were submitted. In the month of October 149,357 units were sold, against 113,005 in October, 1906. The total generated were respectively 174,110 and 136,144 units, the maximum loads 960 and 835 kw. The coal consumption per unit was 8 lb. against 9·93 lb. a year ago, and the works cost 0·853d. compared with 0·970d. per unit sold. In the month of November 162,296 units were sold, against 144,399 in November, 1906. The total generated were respectively 183,326 and 162,699 units, the maximum loads 1,011 and 894 kw. The coal consumption per unit was 8·23 lb. against 8·35 lb. a year ago, and the works cost 0·720d. compared with 0·709d. per unit sold.

The Tramways.—The Board of Trade has written concerning the North Staffordshire Tramways that they have consented to the use of electrical power in Hanley. Col. Druitt reported that he had inspected the North Staffordshire Tramways, with reference to an application by the Potteries Electric Traction Company for a renewal of the consent of the Board of Trade for these tramways to be worked by electric traction. He said that in Hanley, two long portions had been entirely relaid as double line with heavy rails (100 lb. to yard), and now the track in this borough on the original tramways was in good order. The state of these tramways was very much better than when he inspected them in March last year, and the company had done their best to get the track into good order as far as they could. They had spent over £20,000 on the renewal of their lines in this district since last year. They were also buying some new cars and repairing some of the old ones. The condition of the track of the old North Staffordshire tramways in Longton, Fenton, and Hanley was now satisfactory, and if a difference could be made between the tramways and these areas to those in Stoke and Burslem, he could recommend the Board of Trade to give a general consent to the tramways in Longton, Fenton, and Hanley being worked by electric traction.

HEANOR: *Proposed Supply of Electricity.*—At a general meeting of the Tradesmen's Association, a report was read of the deputation appointed to visit Ilkeston and Long Eaton electric light stations. The estimate of the cost of laying cable was stated to be 8s. per yard. At Ilkeston the price was 3d. per unit, and there was a profit of £2,400 last year. Long Eaton, with 10 miles of cable, cost £25,000, and charge 3½d. per unit. A committee was appointed to appear before the Heanor Council with a view of securing electric light for the district.

HENDON: *Electric Lighting Order.*—A Provisional Order is being sought under which it is proposed to transfer the Hendon Electric Lighting Order from Messrs. Crompton & Co., Ltd., to a company known as the Hendon Electric Supply Co., Ltd. The committee recommended that subject to proper Parliamentary undertaking being given by Messrs. Crompton & Co., under agreed terms, the Council offered no opposition to the transfer. The Board of Trade notified the Council that as the Board had now received their inspector's certificate saying that the sum expended upon the works executed within the area of supply under orders, the Board now proposed to release the deposit placed with it when the undertaking was commenced.

LEEDS: *Tramway Receipts.*—The receipts of the Leeds city tramways last week amounted to £6,022, as compared with £5,788 in the corresponding week of last year, an increase of £233. The number of passengers carried during the week was 1,371,652, an increase of 47,253. The total receipts during the present financial year amount to £274,710, as compared with £265,175 at the corresponding week of last year, an increase of £11,534.

LONDON: *County Council Trams.*—At a meeting held on Tuesday last, the chairman of the Highways Committee said that he was unable to give any definite date when the reconstruction, on the "G.B." surface system, of the tramways in Mile End Road would be completed.

The receipts of the London County Council tramways show a substantial increase over those of last year. The County Council has now in operation 116 street miles of track. During the week ended January 18th this year, the electric cars carried 5,561,684 passengers, as against 3,966,428 of the corresponding week of last year. The traffic receipts were £24,655 against £17,612, or an increase of £7,043 for the week. From April 1st, 1907, to January 18th of this year, the traffic receipts on the electrified tramways was £990,208, an increase of £371,702 compared with the corresponding period of the former year.

Forest Hill: The Proposed Tramways.—A deputation representing Lewisham Borough Council, and the Sydenham and Forest Hill Tradesmen's Association, are to wait upon the Highways Committee of the L.C.C. to impress upon them the necessity of connecting up the Forest Hill district with the general system. The L.C.C. have obtained Parliamentary sanction to construct lines which would link Forest Hill to the Lewisham High Road service on one side, and to that at Dulwich on the other. The difficulty which is hindering the service, is that the L.C.C. and Lewisham Borough Council cannot agree as to the method of transmission, as the L.C.C. want to put down the overhead system, and the Borough Council oppose it. It is proposed to take a vote of the residents of the district on the subject, and that the Borough Council be guided by that vote.

Hammersmith: Tramways Extension.—With a view to the ultimate use for traffic of the tramway across Hammersmith Broadway, the London County Council has agreed to contribute £30,000 (or two-thirds) towards the cost of widening the thoroughfare in order that the Borough Council might proceed with the negotiations. Half the contribution will be charged, when the line is used for traffic, to the tramways account.

Islington: Electricity Plant Extensions.—The Borough Council has decided to put down new plant at a cost of £23,000. Owing to a breakdown of plant just before Christmas, practically doing away with all their reserve plant, for the time being, the Council apparently has been stimulated to provide additional spare plant.

Marylebone: Electric Cookery Exhibition.—The Electricity Committee has prepared a pamphlet descriptive of the generating station and electricity undertaking, which is to be printed at a cost of £50 for 500 copies. The pamphlet is to be on sale to

Digitized by Google

ratepayers at one shilling a copy. Messrs. D. H. Evans & Co., of Oxford Street, are giving for two weeks a demonstration of electric cooking apparatus, and a request from the firm to be supplied with the necessary current free has been granted. Messrs. Evans have allowed the use of a stall on their premises for the purpose of exhibiting the Council's pamphlets, &c.

Stoke Newington: Proposed Generating Station.—At the last meeting of the Borough Council, deputations of ratepayers were received in opposition to the proposed scheme for the establishment of a generating station. It was reported by the joint committee of the Electric Lighting and Public Health Committees that they had communicated to the North Metropolitan Electric Power Supply Co. a suggestion that a supplementary agreement should be entered into, setting out the charges in respect of the proposed extensions, which are to be charged against the general revenue, and to be borne by the company, and the company had agreed thereto. The joint committee recommended the agreement for sealing by the Council. The recommendation was carried. A debate, extending over four hours, ensued upon the motion for the adoption of the joint report of November 15th last, recommending the erection of a generating station, and the provision of plant, at an estimated cost of £3,700. In the result the motion was carried by a majority of two.

PLYMOUTH: *Electricity Returns.*—A return made by the Electrical Engineer for the quarter ended December 31st, 1907, shows that in that period 688,013 units were sold, producing receipts of £7,701, against 624,387 units and £7,195 in receipts for the corresponding quarter last year. The income from private lighting for the three months was £4,628, as against £4,572, and for motors £171 against £123 for the corresponding period of the previous year.

Tramways Committee Report.—On the 20th inst. the Plymouth Tramways Committee dealt with the financial estimates for the ensuing year, when the income was estimated at £34,776 and the expenditure at £34,628. The monthly traffic returns showed total receipts for the five weeks ended January 11th of £2,912, compared with £2,782 in the corresponding period of last year, an increase of £130. The average consumption of current per car mile was 1·43 units, as against 1·44 units last year, although the current consumed amounted to 106,978 units over a mileage of 74,521, compared with a consumption of 95,209 units and a mileage of 67,206. Up to January 11th the total income of the undertaking from the beginning of the present financial year amounted to £27,390 and the expenditure to £26,480, while last year the corresponding figures were respectively £26,870 and £25,920.

RICHMOND: *Electrical and Trades' Exhibition.*—The success of the present Electrical and Trades' Exhibition now being held at Richmond undoubtedly owes much to the co-operation of the Richmond (Surrey) Electric Light and Power Co., Ltd. The company gave considerable assistance in various ways in organising the electrical exhibits. The cookery section is particularly prominent, and included a very comprehensive set of apparatus kindly lent by the British Thomson-Houston Co. The ironing and goffering electric equipment shown by the Sheen Laundry Co. was of great interest. The display of the new metallic filament lamps was a great point of interest, especially to the shopkeeping visitors. The number of visitors and the resulting business most certainly fulfilled all expectations.

SHEFFIELD: *Tramway Reports.*—In a report just issued by Mr. A. R. Fearnley, the tramways manager, it is shown that during the nine years of its existence the system has been extended to four times the length the lines were when owned by the company. There are now 268 cars, of which 100 are covered top deck cars, 110 open top, and 58 are single deck cars. The Corporation is now manufacturing its own cars, and has made twelve in the last two years. The generating costs at the power house are extremely low, being only 0·658d. per unit. There are 73 miles of overhead trolley wire, and during the last two years about 25 miles of wire has been renewed. On an average each car runs 117 miles per day, and accidents have been very few, the compensation for injuries, which have mostly been caused by people getting on or off cars in motion, works out at 4·233d. per 1,000 passengers. The system employs 1,500 men. The total number of miles run in 1907 was 7,000,000; number of passengers carried, 74,000,000; traffic receipts, £287,000; and working expenses, £170,000. The receipts per car mile equal 9¾d. and the working expenses 5·963d., leaving 3¾d. per car mile profit.

STOURBRIDGE: *The Electric Lighting Order.*—At a special meeting of the Stourbridge Urban Council, held on the 21st inst., it was stated that a deed of transfer had been executed between the Council and the Shropshire and Worcester Electric Power Co. (Ltd.), by which the company are to pay the Council £500 and all costs.

WEST HAM: *Electricity Estimates and Expenditures.*—The Tramways Manager (Mr. H. E. Blain) reported on Monday as to the cost of roof covers for tramcars constructed in the Council's depôt. The cost for 20 covers worked out as follows:—Materials, £817; wages, £523; total, £1,340, or £67 per cover. The former contract price paid to Messrs. Milnes, Voss & Co. was £97 per roof cover. Alterations of seats were made on the cars dealt with by the Council, and the cost of these was £131 11s. 6d. Ten per cent. is to be added to the cost of the work done in the Council's depôt to cover establishment charges, and this amount, £147 3s. 3d., will go to the credit of repairs and maintenance of cars. The Committee has decided in favour of 20 additional cars being fitted with covers at the Council's depôt, the cost to be charged to the revenue account in the ensuing financial year.—The Electrical Engineer (Mr. Seabrook), in a report as to the loan for extensions at the generating station applied for in 1906, states that up to September 30th, 1907, £14,564 had been spent, against the estimate of £17,076. Balances on contracts, if all paid, would amount to £3,541, on a total against the estimate of £17,905. The difference is £829, and is partly caused by the item mechanical stokers estimated at £2,600, which cost £3,175 12s. 5d., as in excavating some old concrete sewage tanks were found, considerably increasing the cost of digging out. Another item exceeded is switchgear and cables for turbo-generators and motor-generators. The expenditure was £2,365 9s. 9d., against an estimate of £1,685, practically all on cable, due to the 37 per cent. rise in the price of copper, and extra runs for motor-generator cables. These machines are at the extreme end of the engine room from the switchboard. One of the engines has been sold to the Government of Uruguay, and a motor-generator is now on its site. The cable recovered has been credited to capital account. At Silvertown the estimate for the work was £17,212, and £22,706 has been spent, owing to more work having been done than was anticipated, and the rise in price of copper and lead, the cost of cable amounted to £12,331, against the estimate of £9,826. The ground covered by mains was 9,197 yards, against 7,496 yards estimated. Conduits and excavation amounted to £6,175 12s. 5d., against £3,441 estimated. The amount allowed for transformers, £2,427, was exceeded by £954 2s. 5d., owing to more transformers being installed than were estimated for, over 1,500 kw., against 1,100 estimated. The amount estimated for distribution was £23,300, and the amount spent £24,022 0s. 10d. The total estimate was £57,588, and the total expenditure £64,632 18s. 1d., the excess being £7,044 18s. 1d. Application is to be made to the Local Government Board for sanction to borrow the £7,045 excess expenditure.

TENDERS INVITED AND PROSPECTIVE BUSINESS

AUSTRALIA.—Capt. R. Muirhead Collins, C.M.G., has also received tender forms, specifications, &c., relating to the following:—Required by the Postmaster-General's Department at Melbourne:—(*a*) Apparatus for exchange: one common battery switchboard, of 30 sections in all, together with all associated frames, racks, power plant, and parts; (*b*) apparatus for subscribers' premises: 3,000 telephone wall sets, 1,000 telephone table sets, 150 extension switches (complete), 70 switchboards for 2 and 6 lines, 50 switchboards for 3 and 10 lines, 10 switchboards for 6 and 20 lines, 10 switchboards for 8 and 50 lines, 200 telephone wall sets, and 100 telephone table sets for party lines. Tenders will be received at the Office of the Deputy Postmaster-General, Melbourne, until 3 p.m., on May 26th.

The representative of the Commonwealth in London (Captain R. Muirhead Collins, C.M.G.), notifies that he has received tender forms, specifications, &c., in connection with the supply and delivery of thirty-three switchboards for private branch exchanges for common battery working, for which tenders will be received at the office of the Deputy Postmaster-General, Sydney, up to 2.30 p.m. on March 4th. Specifications, tender forms, &c., may be obtained at the Commonwealth Offices in London, 72 Victoria Street, S.W., where also preliminary deposits on tenders may be paid. Copies of the specification and conditions may be inspected at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

BELFAST.—Tenders are invited by the Corporation for the supply of low-tension cable during the twelve months ending March 31st, 1909 (see an advertisement this week).

BRISTOL.—The Docks Committee invite tenders for the supply, delivery and erection, and maintenance for 12 months after they have been in use, of electric cables for the supply to Avonmouth Docks. The tenders are also to include the construction, delivery, erecting in place, fitting, completion, and testing and the maintenance for 12 months after they shall have been taken into use of the electric lighting installations, complete in all details, for the various buildings, railway yard, wharves, &c., at the Royal Edward Dock, now in course of construction at Avonmouth. Specifications, &c., from the Secretary of the Docks Committee (fee £5, returnable), and tenders to 19 Queen Square, Bristol, by February 17th.

BURNLEY.—Tenders are invited for the supply of a booster to the electric lighting station at Burnley Union Workhouse. Tenders should be sent in by February 12th.

Digitized by Google

CLONES (IRELAND).—The Urban District Council is inquiring into the possibility of electric lighting for the district.

EDINBURGH.—Tenders are invited for an extension switchboard panel. Specifications, &c. (fee, two guineas, returnable), from Sir Alex. B. W. Kennedy, the consulting engineer to the Corporation, 17 Victoria Street, London, S.W., and tenders to the Town Clerk by February 10th. (See an advertisement this week.)

HULL.—The Education Committee of the Corporation invite tenders for an electric light installation and fans at the Selby Street West School, now in course of erection. Full particulars may be obtained from the City Architect, and tenders should be sent to the Town Clerk by February 10th.

KINGSTON-ON-THAMES.—Application is to be made to the Local Government Board for sanction to borrow £12,600 in connection with the electricity undertaking.

LEEDS.—Tenders are invited by the Electric Lighting Committee for steam, exhaust, overflow, and other pipes, valves, &c., in connection with a steam turbo-generator of 3,000 kw. capacity. Particulars from H. Dickinson, manager, the Whitehall Road, Leeds (fee, two guineas, returnable), and tenders to the Town Clerk by February 10th.

The Tramways Committee invite tenders for the supply of stores during the year ending March 31st, 1909, including electrical sundries.

Tenders are also invited for the supply of steam coal for the generating set for six, nine, or twelve months' supply. The consumption is approximately 500 tons per week; also for the supply of household coal and delivered at the various offices and depôts as required. Particulars may be obtained from the General Manager, at the Tramway Offices, City Square, Leeds, and tenders should be sent to the Town Clerk not later than February 21st.

LONDON: *London County Council.*—The Council invites tenders for (*a*) the manufacture, delivery, and laying of about five miles of low-tension, lead-covered electric cable, and about two miles of telephone cables, &c.; and (*b*) the laying of stoneware cable ducts, building manholes, repaving, &c., for the reconstruction for electric traction of the Council's tramways in Caledonian Road and Seven Sisters Road. Tenders to the Clerk by February 4th.

Bermondsey.—Tenders for the supply of the following stores during the year ending April 1st, 1909, are invited:—Arc lamp carbons and brushes, cable and jointing material, conduits, electricity meters, demand indicators and main fuses, engine oils, meter boards, street frames and covers and joint boxes. Full particulars from the Electrical Engineer, and tenders to the Town Clerk by February 17th.

Fulham.—A site is to be selected by the Electric Lighting Committee upon which to erect a sub-station, and put in the necessary transformers and cable connections, at an estimated cost of £400. Two flame arc lamps are to be put up in Wandsworth Bridge Road at an estimated cost of £17 10s.

Hammersmith.—The Electrical Engineer has prepared reports upon immediate extensions of plant, &c., and further developments at the generating station. He states that it is imperative that the boiler plant be increased by placing two boilers in the No. 1 boiler house and equipping all five boilers with forced draught. His estimate for this work is £4,400. Switchboard accommodation: He also recommends the addition and removal of the main switchboard. This work can only be carried out in sections, and will take some time to complete, as the supply must be maintained. £1,000 is the estimate for this. A sub-station, which it is suggested should be put up in the Hammersmith Road, will cost £283. Provision should be made for five 100-kw. transformers at £114 each. Extensions of mains are estimated at £1,899. Services, upon which £1,038 has been overspent, are estimated to March 31st, 1909, at a further £3,000. The Electricity Committee have approved the Engineer's report, and the Finance Committee likewise have passed an estimate for the work suggested to the total of £12,190. Application is to be made to the L.C.C. for a loan of £10,000 on account.

Islington.—The Borough Council invite tenders for the supply of the following stores during the year ending April 1st, 1909: Engine-room stores, &c., arc lamp carbons and globes, oil, transformers and accessories, &c.; electricity supply meters, prepayment meters, cables; electrical sundries: lamps, brushes, arc lamp parts, **&c.; terminal** service and network boxes. Particulars from the Town Clerk, to whom tenders by February 18th.

Tenders are also invited by February 25th for (*a*) one 1,500-kw. steam-turbine alternator, &c., (*b*) water-tube boiler, conveyor, &c (see an advertisement this week).

OLDHAM.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £1,500 for the provision of electricity meters. There was no opposition.

PORTSMOUTH.—The Tramways Committee invite tenders for the supply of points, crossings, and junctions. Full particulars from the Tramway Manager, and tenders to the Town Clerk by February 3rd.

Tenders are also invited by February 3rd for the supply of best smokeless Welsh steam coal for periods of six or twelve months.

RATHMINES AND RATHGAR.—Tenders are invited for the supply of the following stores during the twelve months to March 31st, 1909:—Coal, arc lamp carbons, incandescent lamps. Tenders to the Town Clerk by February 15th.

RAWTENSTALL.—The Corporation invite tenders for the supply of one balancing set, one rotary transforming set, direct to alternating current: eight static transformers, and also Lancashire boilers with condensers fitted with circulating pumps, pipe works, &c. Copies of the general conditions, &c., may be seen at the offices of Messrs. Lacy, Sillar & Leigh, 2 Queen Anne's Gate, Westminster, or 78 King Street, Manchester, and obtained on payment of a fee of £2 2s., returnable. Tenders to the Town Clerk by February 7th.

SHEFFIELD.—Tenders are invited for a supply of stores as follows for the twelve months ending March 25th, 1909:—Electrical supplies and fittings, cable, car fittings, car lamps, wood slipper blocks, steam tubes and fittings, overhead line material. Full particulars from the General Manager, Tramway Department, Division Street, Sheffield, to whom tenders by February 10th.

SOUTHAMPTON.—The Tramways Committee recommend the purchase of three additional tramcars at £2,000, and as a result of a discussion in the Council, it has been referred to the Committee to consider the question of adopting tramcars with top covers.

TUNBRIDGE WELLS.—Tenders are invited for the annual supply of high- and low-tension cables. Particulars from the Consulting Engineer, Mr. Horace Boot, Electricity Works, and tenders by February 1st.

WEST HAM.—Tenders are invited for the supply of engine-room stores, rubber-covered cable electric wiring materials and accessories, and chemicals. Particulars from the Borough Electrical Engineer's office, 84 Romford Road, Stratford, E. Tenders by February 6th.

The Engineer has submitted the following estimates as to capital requirements until March 31st, 1910:—Five chaingrate stokers and driving gear, £1,750; feed-water purifier, capacity 8,000 gallons per hour, £550; feed-water settling tank, capacity 38,500 gallons, £500; feed-water pipework, £450; boiler house sundries, testing apparatus, &c., £300; railway siding, £1,000; ash conveyor, 400 tons per hour, £1,200; grab, £175; switchgear, exciter switchboard, £150; cellular switchgear, to complete gear on present level, £600; platforms and stairway, £475; switch cells and operating gear, £1,350; pressure regulators and instruments, £300; testing cables (water load), £400. Step-up transformers—two transformers (500 kw.), £600; cellular control and isolators, £200. Turbine generators—one 1,500-kw. turbo generator, £7,900; pipework, £400; foundations, £200; cables, £250; sundries, £200; one 3,000-kw. turbo-generator, No. 12, £10,000; pipework, £600; foundations, £450; cables, £480; sundries, £300. Circulating water equipment—Spray coolers (750,000 gallons per hour), £3,000; increasing capacity of circulating water supply from the river, £1,600; circulating water sundries, £100. Station lighting and power—Transformer chamber, £400; tools and tackle, not workshop tools, £200; workshop tools, £500; office sundries, £50. Total, £36,630. High-tension triple concentric feeder to Silvertown, £4,000; switch and transformer chamber, £500; H.T. cable, £3,000; E.H.T. cable, £4,000; L.T. cable, £1,500; conduits and ground work, £5,000; transformer chambers, switchgear, &c., £8,000; meters, £2,000; testing apparatus, £250. Total, £28,250. Application is to be made to the Local Government Board for sanction to borrow this sum. The Electrical Engineer is to be empowered to invite tenders at once for the turbo-generator included in the estimate.

WIMBLEDON.—The Corporation invite tenders for the supply and erection of the undermentioned plant at their electricity works, and are prepared to accept tenders subject to the sanction of the Local Government Board being obtained for the necessary loan:—(*a*) A 1,000 kw. turbo-alternator, with condensing plant; (*b*) two water-tube boilers, economisers, pipe-work, and feed pump; (*c*) high-tension main switchboard and switchboard gallery. Forms of specification and tender, with the general conditions, may be obtained from Mr. H. Tomlinson-Lee, the Borough Electrical Engineer, Electricity Works, Durnsford Road, Wimbledon (fee £1 each specification, returnable), and tenders to the Town Clerk by February 18th.

YARMOUTH.—Tenders are invited for the supply, delivery, and erection of a 400 kw. continuous-current traction generator. Particulars and forms of tender from the Borough Electrical Engineer, 20 King Street, Great Yarmouth (fee £1 1s., returnable), to whom tenders by February 1st.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The New South Wales Postmaster-General's Department has accepted the tender of Mr. R. B. Hungerford (Sydney) for 500 telephone wall sets at £2 10s. 6d., and 100 party line sets at £3 2s. 6d. each.

CARDIFF.—At a special meeting of the Electrical and Tramways Committee on Tuesday, the following tenders were accepted:—British Insulated & Helsby Cables, Ltd., high-tension cables at £593; British Westinghouse Electric & Manufacturing Co., 700-kw. motor generator for the Hayes sub-station at £1,345.

EAST PRESTON GUARDIANS.—The East Preston Guardians have received alternative tenders for electric and gas lighting.

Digitized by Google

Messrs. Foote & Milne, of London, have sent in two tenders for electrical installations at £1,152 and £996 respectively, whilst the Littlehampton Gas Company have sent in an amended offer for a gas supply at 3s. 9d. per 1,000 cubic feet, and also to lay inside and outside piping, &c., at £217 10s. After a long discussion the consideration of the matter was deferred for a fortnight.

EAST HAM.—The Town Council has accepted the quotation of Callender's Cable and Construction Co., Ltd., for cable at £224 7s. 1d.

ELECTRICAL INSTALLATIONS, LTD.—We understand that Electrical Installations, Ltd., have some important contracts on hand, including a complete power, light, and telephone equipment for the Marmite Food Extract Co., Ltd., at their new factory, Camberwell. Installations are also being provided for, among others, the London and Paris Exchange, Parr's Bank, Ltd., Slater's, Ltd., Oxford Street, &c., &c. An elaborate system of secret service telephones and bells has just been installed for Messrs. S. Pearson & Sons, Ltd., contractors, at their new offices, the old Whitehall Club, Parliament Street, S.W.

FINCHLEY.—The Council received 21 tenders for the supply and erection of a 350-kw. high-speed engine and dynamo combined, with spare parts. The lowest was that of the British Electrical Plant Co., at £2,521. The Electricity Committee, with the Electrical Engineer, Mr. E. Calvert, have the tenders under consideration.

LONDON: *London County Council.*—The following tenders for 500 tons of steel slot rails and 190 tons of conductor rails for the reconstruction of the Caledonian Road and Seven Sisters Road tramways have been received:—The Frodingham Iron and Steel Co., Ltd. (accepted), £5,654 5s.; Walter Scott & Co., Ltd., £6,490; Steel, Peech & Tozer, Ltd. (incomplete tender for slot rails only), £4,462 10s. The Chief Engineer's estimate was £5,622 10s.

The Council has accepted the tender, at £6,392 12s. 11d., of Wimpey & Son for paving works in connection with the Hammersmith to Harlesden tramways. Although this was not the lowest tender, it was thought best that Messrs. Wimpey should have the contract, so that the paving and trackwork may be completed together. The lowest tenders were Underwood Bros., Dukinfield, Cheshire (£6,142 19s. 11d.).

Hammersmith.—The Borough Council has received the following tenders for the construction of a sub-station in Hythe Road:—Cowans, Ltd. (accepted), £212 15s.; Ferranti, Ltd., £215 8s. The Council has also accepted an offer from the Crynant Colliery Co., Ltd., to supply the generating station with 3,000 tons of Crynant coal at 15s. 4d. per ton. Owing to the acceptance of this quotation the price of the 1,000 tons ordered from the company in June last is to be reduced from 16s. 10d. to 15s. 10d. per ton.

Lambeth.—The Borough Council has placed an order with the General Electric Co., Ltd., at £150, for the supply of 1,000 Osram lamps for the Town Hall.

Stepney.—The Borough Council has received the following tenders in connection with the electricity supply undertaking:—Thirty-seven street boxes: Universal Electrical Manufacturing Co. (provisionally accepted at £62 11s. 3d), original tender £74 12s., subsequently reduced to £62 11s. 3d. by the company in consequence of themselves having received a more favourable price for castings; British Insulated and Helsby Cables, Ltd., £65 10s.; Lucy & Co., Ltd., £73 17s. 6d.; Henley's Telegraph Works Co., Ltd., £85 2s. 6d.; Richmond & Co., £117; J. Every, £120 17s. 6d.; Reason Manufacturing Co., £135 15s. 6d.; W. Cottis & Sons, £143 19s. Twenty-five large and 25 small cast-iron chambers for containing street disconnecting boxes:—E. & J. Wright (incomplete), £68 15s.; J. Every (accepted), £82 10s. 4d.; J. Warner, Ltd., £92 10s.

Woolwich.—The Borough Council has placed an order with John Spencer & Co. for the supply of pipework for connecting up the new boilers at the generating station at £11 5s.

RAWTENSTALL.—The Corporation have accepted the tender of Messrs. W. T. Glover & Co., for electric lighting and tramway cables, and that of Messrs. Browett, Lindley & Co., for steam generating sets.

WEST HAM.—The Electricity Committee has agreed to extend the contract of Messrs. W. Lucy & Co., Ltd., for the supply of house cut-out boxes for two years from March 31st next, the contract price being subject to a reduction of ten per cent. on payment of the account within seven days from the date of delivery.

Fire at a Paris Generating Station.—On the 23rd inst. a fire broke out in the electricity generating station, which is situated below the Central Markets. There was an extinction of the lighting in the Avenue de l'Opéra. The firemen had great difficulty in subduing the fire, and owing to the great number of cables destroyed the generating station will be unserviceable for some time, and a large part was without electric light for three days.

COMPANIES' MEETINGS AND REPORTS

CENTRAL LONDON RAILWAY.—The report for the half-year ended December 31st, states that the the capital expended during that period amounts to £19,482. The chief items are for the additional generating plant at the power-house and the new line at Shepherd's Bush. Compared with the corresponding period in 1906, there has been a decrease of £18,508 in the revenue receipts and of £5,152 in the working expenses; rates and taxes have decreased by £168. The available balance is £59,620. The number of passengers carried during the half-year amounted to 16,646,620, compared with 20,721,508. The decrease in the number of ordinary passengers carried during the half-year is 3,710,636, and of workmen 364,252, the total decrease being 4,074,888, or 19·67 per cent., compared with the corresponding period. An arrangement, subject to one month's notice, has been entered into with the omnibus companies, in accordance with which they reduced the length of their penny fare sections on the route of the Central London Railway, the latter retaining the minimum fare of 2d. The average receipt per passenger for the half-year is 2·01d., as compared with 1·84d. in the half-year ended December, 1906. The cost per passenger is 1·28d., as compared with 1·09d. in the corresponding period. Continued attention has been given to the reduction of the working expenditure, to lessen, as far as possible, the loss resulting from the diversion of traffic by omnibus and other surface competition, as well as from the opening and development of other tube railways; and with the same view improvements in the working and controlling of the trains have been adopted. After providing for interest on the debenture stock and other payments, the net revenue, including £25,891 brought in from previous half-year, shows a balance of £70,750. The directors recommend the declaration of the following dividends:—On the undivided ordinary stock, at the rate of 3 per cent. per annum for the half-year; on the preferred ordinary stock, at the rate of 4 per cent. per annum for the half-year; on the deferred ordinary stock, at the rate of 2 per cent. per annum for the whole year. After providing for these payments there remains a balance of £20,218. Of this balance £10,000 is to be credited to the reserve fund, and the £10,218 remaining is to be carried forward. The directors also propose that the outstanding accounts for Parliamentary expenses incurred in the promotion of the company's Bills in the sessions 1901 to 1905 be now cleared, and that the amount, £25,366, be charged to the reserve fund, leaving a credit balance of £72,880 at that account. The locomotive account placed in suspense in 1903, pending the sale of the materials of the superseded engines, is now closed, and the balance of £66,590 has been re-transferred to the capital account. The line from Shepherd's Bush Station to the depôt is in course of construction, and is to be completed in time for the opening of the Franco-British Exhibition in May next. A new station is being provided, immediately opposite the entrance to the Exhibition. In addition to the through booking arrangements with the Charing Cross, Euston & Hampstead Railway Co., and the Baker Street & and Waterloo Railway Co., similar arrangements are now being entered into with the Great Northern, Piccadilly & Brompton Railway Co., and the City & South London Railway Co. From 10,000 to 12,000 passengers are at present through booked daily.

DIRECT UNITED STATES CABLE.—At the annual general meeting on Tuesday, the report and accounts, abstracted in our last issue, were adopted. There was a decrease of about £2,000 in the receipts, principally during August and September last, which is attributable to the financial crisis in America, and with the steadier conditions now prevailing, a return to the normal traffic is confidently anticipated.

DUBLIN UNITED TRAMWAYS (1896).—The report and accounts for the half-year ended December 31st, 1907, show that the amount available for division is £64,840 11s. 6d., out of which it is recommended that dividends be paid for the half-year at the rate of six per cent. per annum on the preference shares, and at the rate of six per cent. per annum, free of income tax, on the ordinary shares, together with a bonus of 1s. per share, also free of income tax, on the ordinary shares. It is proposed to set aside £5,000 to reserve and renewals fund, £1,000 to accident insurance fund, £10,000 towards reconstruction and maintenance, and £2,000 as further provision against the guarantee to the Irish International Exhibition, 1907, in addition to the £6,250 already paid in respect of this guarantee and charged to revenue in these accounts. The dividends recommended and the sums added to reserve, &c., will absorb £56,100, leaving £8,740 11s. 6d. to be carried to next account. The meeting will take place on Tuesday.

EAST LONDON RAILWAY.—At the half-yearly general meeting on Monday, Lord Claud Hamilton, the Chairman, said the decrease of £2,023 in their passenger receipts was mainly due to the withdrawal of the Metropolitan Railway Co.'s through train service between Hammersmith and New Cross, in consequence of the non-electrification of the East London line. He said that it really surpassed the wit of man under existing conditions to find an effective remedy. As a company they were absolutely unable to find the money for the electrification of their line without the help of the lessee companies, but neither of the lessee companies would move, whilst both

Digitized by Google

the District and the Metropolitan companies would, he thought, gladly see a resumption of the through services. Their own experience of electrification had not been of such a character as to tempt them, or even to justify them, in coming to the assistance of the East London company. The experience of these two companies of electrification, from a shareholder's point of view, had proved a disappointment, though it had conduced both to the advantage and to the comfort of the travelling public, but he did not despair of the enterprise of those two railways being ultimately rewarded. One thing was certain, they could not go back to steam; they must continue in the course they had laid down for themselves; and that being so, he trusted they might be induced—both in their own and the public interests—to join in some scheme which would result in the resumption of the through traffic over an electrified East London railway. If any scheme could be devised by which any of the other railway companies would contribute towards the electrification of the East London line, he would do all he could to induce the Great Eastern Railway Co. to become a party to it.

METROPOLITAN RAILWAY.—The report of the directors for the half-year ending December 31st, 1907, shows that the total receipts (deducting this company's proportion of the revenue of the City lines and extensions) have been £347,651 7s. 11d., and the expenses £191,959 7s. 4d., leaving a profit of £155.692 0s. 7d. Compared with the corresponding half-year of 1906, the receipts show an increase of £3,775 11s. 7d., and the expenses a decrease of £5,914 7s. 8d. The net revenue account, after providing for the interest upon the debenture stocks and other fixed charges, and the dividend upon the preference stocks, and placing £6,000 to the depreciation fund, shows a balance of £19,845 15s. 10d. available for dividend upon the ordinary stock. The directors accordingly recommend the proprietors to declare a dividend upon the ordinary stock, for the past half-year, at the rate of 10s. per cent. per annum, and to carry forward the balance of £5,515 12s. 9d. to the next half-year's accounts. The Surplus Lands Committee announce, as shown in the report and accounts appended hereto, that the dividend on the surplus lands stock, for the past half-year, will be at the rate of £2 15s. per cent. per annum. Reference is made in the report to the conference which was formed a short time ago of representatives of the various passenger-carrying companies in London with a view to limiting competition, adjusting fares, arranging through bookings, &c. It is hoped in this way to help the interests of the companies concerned and at the same time to give increased travelling facilities to the public. All the electric underground lines likely to be made are now open, the report continues, and it is possible to gauge the effect they may have upon this company by diversion of traffic. On certain routes the loss has been considerable, but the extra accommodation which all these lines afford has induced a large increase in the travelling habit of the people of London which will no doubt further grow, and the directors have every reason to think that any loss incurred on particular routes will soon be balanced by gains in other directions. The result on the traffic of the electrification of the Hammersmith and City line and its extension to Addison Road has been satisfactory, and an appreciable increase is shown in the business in consequence. In conjunction with the Great Western Company, who are partners in the line, it has been arranged to build a special station where the railway abuts on the site of the Franco-British Exhibition, with an entrance directly into the Exhibition grounds. From this it is expected that a large business will result during the ensuing summer. The directors regret that during the half-year two accidents have happened—one at West Hampstead, and the other at Farringdon Street. To meet the expenses arising from them it is proposed to take £4,500 from the reserve fund. The directors greatly regret to report that in consequence of failing health Col. Mellor has felt compelled to retire from the Board after having been associated with the company for twenty years. Mr. Thomas Parker, M.I.C.E., under whose direction the electrification of the line was carried out, has been elected to fill the vacancy. The accounts show that the company now has 20 electric locomotives, an increase of 10 during the half-year. The only other items in the rolling stock for electric traction that has increased during the half-year is the number of compartment coaches converted to trailer coaches, these now standing at 12 instead of 10. The other items are as follows: Motor coaches, 102; trailer coaches, first class, 76; composite, 20; third class, 96; converted compartment coaches, motors 4, first class 4, composite 4. The electrical renewal and depreciation fund has been credited with £6,000, and this now stands at £30,000. The mileage run by the electric passenger trains during the half-year under review was 1,545,149. The annual meeting was held yesterday.

"Whittaker's Arithmetic of Electrical Engineering." (London: Whittaker & Co.) 1s.

"Wireless Telephony" in Theory and Practice. By Ernst Ruhmer. Translated from the German by Dr. J. Erskine-Murray, with an Appendix by the Translator. (London: Crosby Lockwood & Co.) 10s. 6d. net.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Son, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net c.i.f. port of arrival, quoted on Tuesday night, was £64 to £64 10s. per ton. (Last week, £65 to £65 10s. per ton.)

HIGH-TENSION SWITCHGEAR.—Messrs. A. Reyrolle & Co. inform us that owing to further facilities in their works they are now able to supply switchgear embodying what is known as the Merz-Price protective system in larger quantities than formerly.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The first meetings of the creditors and contributories, under the winding up order of Messrs. Johnstone, Benjamin & Co., Ltd., electric wire and cable makers, Kentish Town, London, were held at the offices of the Board of Trade, Carey Street, before the Official Receiver, last week. The winding up order was opposed on behalf of the directors by Mr. B. T. Norton, the receiver for the debenture holders. Gross liabilities amount to £6,296, of which £3,134 15s. 9d. rank for dividend against assets, estimated to produce £3,257 0s. 11d., and as regards creditors a total deficit of £6,959 10s. A committee of inspection has been appointed. Among the creditors are the following:—Electrical Co., Ltd., £162; Fielding & Platt, Gloucester, £65; Felten & Guilleame, Carlswerk-on-Rhine, £95; Kynoch, Ltd., Birmingham, £77; Land & See Kabelwerke, London, £151; Leyland & Birmingham Rubber Co., Leyland, £140; Union Cable Co., Ltd., London, £19.

Creditors of the Victor Arc Lamp Co. are required to send in particulars of their claims to the liquidator, Mr. W. C. Penny, Clarence House, 8 Arthur Street West, London, E.C., on or before February 22nd.

The discharge of Albert Dickinson, electrical engineer, 19 Upper Mill Hill, Wortley, Leeds, has been suspended for two years.

An order for immediate discharge has been issued in the bankruptcy of Samuel Henry and James Edgar Thompson, trading as Thompson Bros., electrical engineers, 6 East Street, Plymouth, subject to bankrupts consenting to judgment being entered against them by the Official Receiver for £50 and £1 10s.

THE FIRE AT MESSRS. COWAN'S WORKS.—In connection with the fire at Messrs. Cowan's Salford works last week, we are informed by the firm that arrangements are being made for a full resumption of work immediately, in order to avoid delay in execution of contracts.

PERSONAL.—The Cheltenham Electricity and Lighting Committee recommend that the salary of Mr. Walter Bache be increased from £400 to £500 per annum.

MISCELLANEOUS CITY NOTES

ANGLO-AMERICAN TELEGRAPH.—After placing the sum of £20,000 to the credit of the renewal fund, the directors recommend the following dividends:—A balance dividend of £1 5s. per cent. upon the ordinary consolidated stock for the year ending December 31st, 1907; a balance dividend of £1 10s. per cent. upon the preferred stock; and a first and final dividend of £1 per cent. upon the deferred stock. A balance of about £2,400 remains to be carried forward. The above dividends, together with those already paid, will amount to £3 10s. per cent. on the ordinary consolidated stock, £6 per cent. on the preferred stock, and £1 per cent. on the deferred stock for the year 1907. The register of transfers will be closed from January 22nd to February 7th, both days inclusive.

BRISTOL TRAMWAYS AND CARRIAGE CO.—Applications were invited last week for an issue at par of £250,000 4½ per cent. mortgage debenture stock. This stock, which is needed in connection with the general development business of the company, will be redeemable in ten years, and is secured by trust deed in favour of trustees giving a special mortgage upon freehold and leasehold properties and a charge upon the undertakings of the company generally.

BRITISH ELECTRIC TRACTION CO.—In a circular to the shareholders the directors state that they have had under consideration the question of the payment of the half-yearly dividend on the 6 per cent. cumulative preference shares on February 15th next, and the majority of the directors are of opinion that this dividend should be paid, but the two directors who joined the Board last year are of opinion, having regard particularly to the present depreciation of some of the company's investments, that the available profits should not now be distributed. In these circumstances the directors, in order to avoid disunion of the Board, which would be prejudicial to the interests of the company, have agreed to the settlement of this question being postponed until the general meeting of the company, which will be held as soon as the accounts for the year ending March 31st next can be presented. An estimate of the profits for the year shows:—Dividends and interest on shares, debentures and Consols, £153,000; interest on loans, &c., £7,200; net profit on working sundry undertakings, £5,500; sundry profits on contracts, &c., £14,000; net profit on sale of

Digitized by Google

investments, £20,000; balance of Bombay profits, £41,900; making a total of £241,600. From this must be deducted :—General and sundry expenses, £24,000; sundry losses and provisions, £12,000; leaving a balance of £205,600. The interest for the year on the first and second debenture stocks amounts to £97,484; and the interim dividend paid on the preference shares from April 1st to August 15th last to £36,754, a total of £134,238. There remains £71,362, to which must be added the balance brought forward from last year, viz., £13,115, leaving £84,477 available for further dividends, and the company has cash in hand to approximately this amount. The half-year's dividend on the preference shares to February 15th requires £48,431.

CENTRAL ELECTRIC SUPPLY CO.—A dividend of 5s. per share is recommended for the year 1907, carrying forward £45.

CITY & SOUTH LONDON RAILWAY CO.—After providing for debenture stock interest, payment of the full dividend on the preference stocks, and adding £1,500 to the renewal fund, there is a balance for the year ended December 31st, 1907, sufficient to pay a dividend of 1¾ per cent. per annum upon the ordinary stock. The sum of £1,119 is carried forward.

GREAT NORTHERN AND CITY RAILWAY.—It is announced that no dividend will be paid on the preferred ordinary "A" shares for the half-year ended December 31st, 1907.

LANCASHIRE AND YORKSHIRE RAILWAY.—A dividend for the past half year at the rate of 4¾ per cent. per annum is recommended. A sum of £32,500 is carried forward.

MARCONI'S WIRELESS TELEGRAPH CO.—An announcement has been made dealing with the postponement of the general meeting beyond the date originally proposed for it. It is stated that a new audit of the accounts has been rendered necessary, and the auditors, Messrs. Cooper Brothers, are now engaged upon it. The accounts will be made up to September 30th, 1907, and the directors propose to hold the general meeting as soon as the accounts are prepared. It is anticipated that the auditors will have finished their work not later than the second week in February, which will enable the directors to call the shareholders together early in March. Mr. Marconi returned to England on the 12th inst., and both from his reports and from the practical tests to which the stations have been subjected in transmitting many thousands of words for Press purposes, the directors are of opinion that the problem of designing stations for establishing wireless telegraphic communication across the Atlantic on a commercial basis has been solved. While continuing the Press service, which has now been carried on successfully for three months, it is proposed to open the stations at the beginning of February for ordinary commercial messages.

RIO DE JANEIRO TRAMWAY, LIGHTING AND POWER.—A telegram has been received to the effect that the first 8,700 h.p. generator in the Rio das Lages power station is now in operation.

ST. JAMES'S & PALL MALL ELECTRIC LIGHT CO.—A dividend of five shillings per share is recommended upon the ordinary shares for the half-year ended December 31st, 1907, making a total of 10 per cent. for the year.

NEW COMPANIES

BECKENHAM HYDRO.—This company was registered on January 10th, with a capital of £500 in £1 shares, to acquire (1) the hydro business carried on at the Mansion, Beckenham; and (2) the business of electrical and medical baths carried on at 16 York Place, Regent's Park, N.W. No initial public issue. Registered without articles of association. Registered office : The Mansion, Beckenham Park, Beckenham, S.E.

ELECTRICAL FITTINGS CO.—This company was registered on January 18th, with a capital of £15,000 in £1 shares (3,000 6 per cent. cumulative preference), to acquire the business of electrical engineers and fitters, manufacturers, and sellers of electrical fittings, &c., carried on by Samuel Heath & Sons, Ltd., at 38 Conduit Street, W., as the "Electrical Fittings Co.," and to carry on the said business and that of electricians, suppliers of electricity for light, heat, motive power, or otherwise, manufacturers of and dealers in electrical apparatus, &c. The subscribers are : S. B. Marshall, A. W. Mills, E. J. Arnold, C. E. Lowndes, J. Thomas, C. M. Field, E. J. Peerless. No initial public issue. The number of directors is not to be less than two nor more than five; the first are S. B. Marshall and A. W. Mills (both permanent), and W. K. Sutton (representing debenture stock holders). Qualification, £100. Remuneration (except managing director) as fixed by the company. Registered office : 38 Conduit Street, W.

LEA, SON & CO.—This company was registered on January 21st, with a capital of £12,000 in £5 shares, to acquire the business of electrical and general engineers, metal workers, dealers in scientific and electrical appliances, &c., carried on by J. A. Lea and J. F. Lea at Shrewsbury, Salop, as "Lea, Son & Co.," and to carry on the same and the business of iron and brassfounders, hardwaremen, &c. The subscribers are :—J. A. Lea, J. F. Lea, S. B. Ebrall, G. Dean, W. Craven, J. Pye, and J. F. George. No initial public issue. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Qualification, £100. Remuneration as fixed by the company.

ROWELL, JONES & CO.—This company wes registered on January 15th, with a capital of £2,000 in £1 shares, to take over the business of general merchants, experts, and contractors carried on by Rowell, Jones & Co., at 27-8, Broad Street Avenue, E.C., to acquire and deal with any right, privilege, concession, or contract for generating, supplying, and employing electricity, galvanism, magnetism, electric, gas or other light or power in any part of the world, and to carry on the business of electricians, electric, water, gas and mechanical engineers, suppliers of electricity, galvanism, magnetism, and gas, &c. The subscribers are :— J. Jones, Mrs. M. C. Jones, C. A. Lewis, A. E. Reiffer, J. Hawkridge, D. I. Evans. No initial public issue. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Qualification, 50 shares.

SQUIRRELL & CO.—This company was registered on January 21st, with a capital of £3,000 in £1 shares, to carry on the business of electrical, heating, ventilating, sanitary, gas, water, and mechanical engineers, builders, &c. The subscribers are :—F. H. Lee, Mrs. R. M. D. Lee, H. T. Squirrell, E. A. Cole, Mrs. H. E. Cole, Mrs. A. Squirrell, and A. T. Gammon. No initial public issue. The number of directors is not to be less than two nor more than five; the first are F. H. Lee and W. F. W. R. Giesler. Qualification, 50 shares. Registered office, 4 Upper Station Road, Bexhill

STONES BROS.—This company was registered on January 23rd, with a capital of £10,000 in £1 shares, to acquire the business of a nut and bolt manufacturer carried on by Mrs. K. Stones at Vulcan Works, Albion, West Bromwich, Staffs., as "Stones Bros.," and to carry on the same and the business of manufacturers of rivets, washers, nails, chains, spikes, couplings, tools, tram fastenings, telegraph fastenings, hooks and rings, &c. The subscribers are :—Mrs. K. Stones, W. Marsh, A. Challingsworth, F. Screen, C. F. Grigg, A. E. Goode, and J. W. Higgs. No initial public issue. The number of directors is not to be less than two nor more than five: the first are Mrs. K. Stones and W. Marsh. Qualification, £300. Remuneration of first directors, £100 each per annum.

Fire at Cowans' Works.—A destructive fire broke out early on the morning of the 21st at the electrical manufactory of Messrs. Cowans, Ltd., of Salford, when a large three-storeyed building in Springfield Lane was destroyed. The fire, owing to the combustible nature of the goods, was very difficult to control, and by eight o'clock in the morning the walls only were left standing. The damage was considerable, and is estimated at £5,000. Messrs. Cowans desire us to state that complete arrangements have been made for full resumption of business, and that all delay is being avoided in the execution of their contracts.

TENDERS INVITED.

CITY AND COUNTY BOROUGH OF BELFAST.

TRAMWAYS AND ELECTRICITY DEPARTMENT.

Low Tension Insulated V.B. Cable.

THE TRAMWAYS AND THE ELECTRICITY COMMITTEE OF THE BELFAST CORPORATION are prepared to receive Tenders for the supply and delivery of Low Tension Insulated V.B. Cable during the twelve months ending 31st March, 1909.

Specifications, with Form of Tender and General Conditions of Contract, may be obtained from the undersigned on making a deposit of £1 1s. for each Specification.

Such deposit will be returned on receipt of a *bona fide* Tender, accompanied by the Specification and General Conditions.

The Corporation do not bind themselves to accept the lowest or any Tender.

Sealed Tenders endorsed "Tenders for Cable" Tramways and Electricity Department must be lodged with Sir Samuel Black, City Hall, Belfast, not later than 12 noon on Saturday, 22nd February, 1908, and must remain open for acceptance until Wednesday, 26th February.

THOMAS W. BLOXAM,
City and Electrical Engineer

Corporation Electricity Works,
East Bridge Street,
Belfast.

PARLIAMENTARY INTELLIGENCE

The London Power Bills to Commence in the House of Lords

Lord Onslow (Lord Chairman of Committees) and Mr. Emmott (Chairman of Ways and Means) decided on Tuesday which Bills in the coming session of Parliament shall commence in the House of Lords, and which shall commence in the House of Commons. As will be seen from the lists below, the three Bills relating to the supply of electric power for London will originate in the House of Lords.

House of Lords.—Bristol Tramways; Croydon and Southern District Tramways; Great Northern, Piccadilly and Brompton Railway; Highgate Hill Tramways; King's College, London (Transfer); London and District Electricity Supply; London and Windsor Motor Roads, Tramroads and Tramways; London County Council (Tramways and Improvements); London Electric Supply; London (Westminster and Kensington) Electric Supply Companies; Metropolitan District Railway; Metropolitan Electric Tramways; South Wales Electrical Power Distribution; West London, Barnes and Richmond Tramways.

House of Commons.—Belfast Corporation; Blackburn Corporation; Bolton Corporation; Burnley Corporation; Doncaster Corporation; Dublin and Central Ireland Electric Power; Kingston-upon-Hull Corporation; Leeds Corporation; Liverpool Corporation (General Powers); London United Tramways; Macclesfield and District Tramways (Abandonment); North-East London Railway; Rochdale Corporation.

Among the Bills which it has been decided shall come before the Police and Sanitary Committee are those promoted by the Blackburn, Burnley, and Kingston-upon-Hull Corporations.

STATUTORY PLANS AND NOTICES FOR RECONSTRUCTED TRAMWAYS.—A Bill is now before Parliament providing for the reconstruction for electric traction of the old cable tramway down Highgate Hill, and the alteration of its gauge to 4 ft. 8½ in. An interesting point to tramway promoters was raised last week, when the Bill was before Mr. Campion for proofs of compliance with Standing Orders. Under the Standing Orders, Bills are divided into first and second class measures. In the latter category are classed Bills proposing absolutely new works, and in connection with which notices have to be served to frontagers, and plans, estimates, and so on deposited in the Private Bill Office. First-class measures are those promoted by existing companies or bodies and which do not relate to absolutely new works, and do not involve notices, plans, and estimates. In connection with the Highgate Hill Tramways Bill, Mr. Pritt, Parliamentary agent, on behalf of the London County Council, argued that this should be considered a second-class measure for the reason that the alteration of gauge constituted a new tramway. Mr. Lees, Parliamentary agent, for the Tramway Company, said that the point had never been raised before the Examiners previously, but it had been tacitly agreed, at any rate since the City of Birmingham Tramways Bill in 1901, that mere electrification of a line should not constitute a Bill a second-class measure. In the case of the Birmingham Bill, for instance, it would have involved an extra expenditure of £5,000. The Examiner, giving his ruling, said it seemed to him that from what had been done in the City of Birmingham case, the mere electrification of a tramway would not constitute a Tramway Bill a second-class Bill, and he did not think the alteration of gauge was sufficient to make a tramway a new tramway.

OPPOSITION TO TRAMWAY BILLS.—The General Purposes Committee of the Wandsworth Borough Council has decided to present petitions against the London County Council (Tramways and Improvements) Bill, the West London, Barnes, and Richmond Tramways Bill, and the Croydon and Southern District Tramways.

LONDON COUNTY COUNCIL AND PRIVATE BILLS.—The following Bills, in addition to those relating to electric power supply in London, mentioned elsewhere, are to be petitioned against by the London County Council:—Great Eastern Railway (General Powers), Great Northern, Piccadilly and Brompton Railway, Metropolitan District Railway, Highgate Hill Tramway, London and Windsor Motor Roads, Tramways and Tramroads, Metropolitan Electric Tramways, West London, Barnes and Richmond Tramways, and London Motor Roadways Approach.

BILLS ABANDONED.—When the Examiner of Standing Orders sat to consider a number of Bills last week, no appearance was entered in respect of the Erith Tramways Bill and the Morecambe Tramways Bill, and the Bolton Corporation Bill, an indication that the promoters do not intend to proceed with their measures. The latter measure proposed, *inter alia*, to revive tramway powers granted in 1887 and the borrowing of £6,100 in putting them into force.

STANDING ORDERS COMPLIANCE.—The following Bills have been sent forward for first reading, Standing Orders having been complied with:—Keighley Corporation, Kingston-upon-Hull Corporation Leeds Corporation, King's College, London (Transfer), Macclesfield and District Tramways (abandonment), Great Northern, Piccadilly and Brompton Railway, Highgate Hill Tramways, North-East London Railway, Croydon and Southern District Tramways, Wolverhampton Corporation, Stockport Corporation, Bromley Corporation, Belfast Corporation, London Motor Roadways Approach, Blackburn Corporation, Bristol Tramways, Rochdale Corporation, South Wales Electrical Power Distribution, Manchester Corporation.

Non-compliance with Standing Orders has been reported in connection with the London County Council (Tramways) Bill. The point involved, however, is a small technical one in regard to the preparation of the Parliamentary estimates, and was not raised by an opponent to the measure.

The West London, Barnes, and Richmond Tramways Bill, the London United Tramways Bill, and the London and Windsor Motor Roads, Tramways and Tramroads Bill, all of which are opposed, will come before the Examiners of Standing Orders on February 3rd.

LONDON ELECTRIC POWER BILLS. The three Bills relating to electric power supply in London, viz., London Electric Supply, London and District Electric Power, and the London (Westminster and Kensington) Electric Supply, have passed the Standing Orders stage, there being no opposition. Some particulars of the action of various local authorities with regard to these Bills are given in another column.

SCOTCH PROVISIONAL ORDERS.—The following Provisional Orders, promoted under the Private Legislation Procedure (Scotland) Act, 1899, have passed the Standing Orders stage:—Ayr Corporation Tramways, Lanarkshire Tramways, Wishaw Burgh Electricity.

PARLIAMENTARY ESTIMATES.—The following estimates of the cost of the works proposed in the following Bills have been deposited in Parliament in accordance with the Standing Orders:—Blackburn Corporation Tramways, £9,119. Rochdale Corporation Tramways, £1,306. Burnley Corporation Tramways, £70,000. Bolton Corporation Tramways, £6,092. Croydon and Southern District Tramways, £59,489. Liverpool Corporation Tramways, £2,900. Doncaster Corporation Tramways, £7,700. London County Council Tramways, £206,890. London United Tramways, £7,598. Ayr Corporation Tramways, £18,250. Kingston-on-Hull Tramways, £74,000. Metropolitan Electric Tramways, £50,744. West London, Barnes and Richmond Tramways, £164,350. London and Windsor Motor Roads Tramroads and Tramways: Tramways, £316,467; motor roads, £1,132,977. Leith Corporation Tramways, £56,722.

MIDDLESEX COUNTY COUNCIL.—Petitions are to be lodged against the Highgate Hill Tramways Bill and the Metropolitan Electric Tramways Bill, in order to preserve the Council's *locus standi* in case of necessity.

Long-Distance Telephony.—It is stated that the Associated Swedish, Danish, and Russian Telephone Co. has increased its share capital by £400,000 in order to put into effect a proposal to link up St. Petersburg, Moscow, Warsaw, Copenhagen, Stockholm, Berlin, Christiania, Frankfurt, and Paris.

Track-Circuit Signalling on the Great Western Railway.—A new installation of track-circuit automatic signalling on a short section of the Great Western Railway is described in the *Railway Gazette*. In common with other automatic systems "normal line clear" working is adopted. The object of this new installation is to shorten a block section of 2¾ miles between Goring and Pangbourne stations, and electrically-controlled intermediate home and distant signals have been provided for both up and down main and relief lines at Basildon, midway between the two stations named. Each line of rails has been divided into track circuits, so that the stop signal at the rear of a train or vehicle standing at any point between Pangbourne and Basildon, or Basildon or Goring, is held at danger until the train has left the section. The track signals are the down advance starting signals for the main and relief lines at Pangbourne, and the starting signals for the up-main and the advance starting for the relief at Goring; also the up and down main and relief home and distant signals at Basildon. The novel feature is that ordinary block working is maintained between Pangbourne and Goring, while the normal position of the signals is similar to all other running signals at danger. The new signals are the tubular post type, with upright rods inside and motor at the base, and are operated electrically by the signalman at the two stations. In the case of the section between his block post and the Basildon signal being clear, the signalman at either Goring or Pangbourne is able to start a train to proceed to Basildon, and he may, in case of the line being clear, operate the automatic signals at Basildon, and clear the section there. The engine of a train operates the starting and distant signals, and these are kept at "danger" until the train has passed over the track-circuited section in advance. During foggy weather or snowstorms, trains are not permitted to proceed from either end unless the entire section is clear. An indicator showing the state of the line up to a point 440 yds. in advance of the respective Basildon home signals is provided in the signal-boxes at Pangbourne and Goring. Immediately the train has passed the respective starting signals the indicator automatically records "Track Occupied," and is so held until the train has passed the clearing point, when "Track Clear" appears, the "Train Entering Section" signal must then be sent and the Basildon signal levers restored to their normal position.

SUMMARY

In two reports, the Highways Committee of the London County Council recommend the construction of tramways in the North and South of London at a cost aggregating £88,226. Messrs. Dick, Kerr & Co. are the successful tenderers for the reconstruction, on the conduit system, of the existing horse tramways from King's Cross to Holloway Road, and from Holloway Road to Finsbury Park. (Page 187.)

At a meeting of the Incorporated Municipal Electrical Association on Tuesday, a resolution was passed to the effect that the Association shall appear at the inquiry to be held by Mr. James Swinburne concerning the draft electrical regulations issued by the Home Office last year, in joint opposition with the Association of Municipal Corporations. At the same meeting resolutions were passed urging the Council of the Association to continue to make efforts to induce the Local Government Board to put the question of wages of permanent employees on a sound basis, and to petition the Board of Trade to introduce the Supply of Electricity Bill this session, with clauses permitting electricity supply undertakers to carry on the wiring of buildings, hiring of fittings and motors, &c. (Page 188.)

We publish some interesting statistics sent us by Mr. J. A. Robertson, on the use of electric power in some shipyards and large engineering works in the neighbourhood of Greenock. (Page 188.)

A Paper on the driving of rolling mills was read by Mr. G. Hooghwinkel recently before the Sheffield Society of Engineers and Metallurgists. The question of cost of power was dealt with, a description was given of various methods of electric driving, and a table of important rolling mill installations was included. A short discussion followed. (Page 189.)

The report of the Yorkshire Electric Power Co. shows that the gross profit for the half-year ended December 31st, 1907, was £836 10s. 5d., compared with a loss of £403 4s. 3d. for the preceding half-year. After payment of mortgage interest, the net revenue account shows a loss of £139 2s. 11d., compared with £1,211 3s. 9d. for the half-year ending June 30th, 1907. Agreements have now been entered into with consumers for a total of 5,548 kw., an increase of 2,426 kw. during the six months. (Page 191.)

A new generating station is under construction at Salt Lake City, the most notable features of which are the use of an unusual type of vertical water-tube boiler and the employment of some of the exhaust steam taken from the first stage of the Curtis turbines for heating purposes, while the remainder passes through a further stage to condensers in the usual way. (Page 192.)

IN the discussion on a Paper by Mr. J. W. GORDON on the new Patents and Designs Act last week, Mr. H. FLETCHER MOULTON said that the Workmen's Compensation Act had provided a very deserving class with their living for some years past, and he trusted that the Patent Act would have the same effect. (Page 193.)

A CONSIDERABLE development of water power for electrical supply is taking place in South Carolina. One of the schemes, that of the Southern Power Co., includes a number of power-houses aggregating some 200,000 h.p. on the Catawba River. One of these stations is already at work, and contains eight 3,000 kw. alternators and two exciter sets. A feature of the installation is the provision for admitting carbonic acid gas into the transformer tanks in case of fire. (Page 195.)

A VERY complete electrical installation is to be found in the Stuyvesant Theatre, New York. The supply company's connections come through two sets of underground mains to the main switchboard, and a very complete arrangement of levers and gang shafts is adopted to actuate the switches and dimmers. Nearly all the lights in the auditorium are placed behind translucent glassware. (Page 196.)

A DESCRIPTION is given of the Berry Series System of alternating-current distribution, in which the heavy all-day losses in transformer substations are avoided by employing a small auxiliary transformer which takes the light load and an automatic switch to transfer the load to the main transformer when it rises above a certain value. (Page 197.)

A NEW form of arc lamp lowering gear is illustrated on page 200.

SOME electrically-driven coal spouts in which coal is conveyed by travelling bands have been installed by the North-Eastern Railway Co. at Tyne Dock, by which vessels can be coaled under all conditions of tide at the quayside. (Page 200.)

THE Paper by Mr. J. S. PECK on protective devices for high-tension circuits, which will be discussed at to-night's London meeting of the Institution of Electrical Engineers, was read before the Manchester Local Section on Tuesday. The author considered the nature of the "static" strains produced by lightning, switching, grounding, or by any occurrence which causes an abrupt change in static potential, which may appear as high pressure to earth or between wires, or as a concentration of potential upon a portion of the circuit. To relieve the high pressure between line and ground or between wires, lightning arresters are used. To protect apparatus from concentration of potential, choke coils may be placed in series with the apparatus to be protected. Lightning arresters usually consist of an air-grip in series with a current limiting and an arc suppressing device. Four types of lightning arresters are in general use—the horn, the multi-gap, the water-jet, and the electrolytic. (Page 201.)

MAJOR PRINGLE, in his Board of Trade report on the West Hampstead accident, finds that the collision was caused by forgetfulness in the first instance, and subsequently by some illegal manipulation of the electrical instruments or locking on the part of the signalman at West Hampstead, who should bear the full responsibility for his conduct. The opinion is expressed at the end of the report that automatic signalling is best adapted for conditions of high traffic frequency. (Page 205.)

A LETTER from Mr. H. L. WEBB calls attention to the development of the central battery telephone system and the message rate tariff on the Continent. (Page 206.)

THE advantages of electrical driving in textile cotton mills were dealt with in a Paper read by Mr. J. SHAW last Saturday before the Dundee Institute of Engineers. (Page 207.)

A NEW iron-clad switch, some new telephone designs, and a new metallic filament lamp are described on pages 207 and 208.

UNDER ELECTROCHEMISTRY AND ELECTROMETALLURGY a number of short notes are given upon various subjects, among them being reference to a patent for using calcium carbide anodes in the production of aluminium, a method for obtaining calcium carbide in cylindrical blocks, and the melting of refractory metals in vacuum by means of the arc. (Page 209.)

AN account of Prof. RUTHERFORD'S lecture last Friday at the Royal Institution appears under ELECTRICAL SCIENCE, together with a note on a new formula for the inductance of a circuit composed of two equal parallel wires. In the Papers abstracted in the Continental section DUFOUR describes another magneto-optic anomaly, which he takes to indicate the existence of positive electrons. MAX WIEN produces slightly damped oscillations by a new method of coupling, KLUPATHY proves the magnetic action of a beam of cathode rays, and LIGNANA describes an improved method of measuring energy in three-phase four-wire circuits. (Page 210.)

AMONGST the specifications published by the Patent Office last Thursday was one by BRUCE PEEBLES & Co. and LA COUR, for the conversion of single-phase currents into polyphase by means of a compensated converter. The ATELIERS-THOMSON-HOUSTON have one dealing with compensated dynamo machines in which the direction of rotation can be reversed. M. BROOKS and M. K. AKERS have an arrangement for regulating and equalising the loads on alternating-current generators. THE BRITISH WESTINGHOUSE ELECTRIC Co. have patented a means for neutralising and preventing disturbances to telephonic and telegraphic communication, due to proximity of the cables to high-tension alternating-power cables or overhead lines. The only expiring patent of electrical interest this week is one by F. TUDSBURY, relating to the method of attaching the collectors in such electric machines as the Wimshurst. (Page 211.)

THE Cardiff Tramway Manager estimates that there will be a profit of £15,000 from the tramway system at the end of the current financial year, compared with £4,000 last year. The Board of Trade refuses to intervene at present in the dispute between the various local authorities of the west of London concerning the alleged noise and nuisance from the tramcars of the London United Tramways Co. Intercommunication has been arranged between the National and municipal telephone systems at Hull. The Leyton District Council calls the attention of the Board of Trade to the delay in the construction of the North-East London Railway, authorised in 1905. The City Corporation is supporting other London authorities in objecting to the proposal by the Board of Trade to modify the existing audit of electric lighting accounts. The Hull Electricity Committee has decided to transfer the whole of the present reserve fund towards extinguishing the capital expended beyond the amount sanctioned by the Local Government Board. The Sunderland tramway returns show a considerable drop during the past year, and are still going down; the decrease is attributed to the extremely bad state of trade and the general distress in Sunderland. Some severe criticisms have been made by the Local Government Board auditor upon the accounts of the Walthamstow Electric Lighting and Light Railway departments, in which it is stated that had certain sums been charged to revenue instead of to capital, there would have been a loss instead of a substantial profit. In consequence of a disagreement between the Midland Electric Corporation for Power Distribution, and the Wednesbury Corporation, as to the terms upon which the present bulk supply shall be continued, the company has given notice to ter-

Digitized by Google

minate the present agreement on March 31st, 1908, and notifies its intention to give a supply direct in future under the terms of its Provisional Order. A reply to the recent criticisms of Mr. Stephen Sellon upon the Dolter Surface Contact System in its application at Oxford, has been made by the engineer to the National Electric Construction Co. (Pages 213 and 214.)

The Ilford Corporation require a 1,000-kw. steam generating set, and a water-tube boiler; Aston Electric Supply Committee recommend the installation of a 2,000-kw. three-phase 6,600-volt turbo-generator; the Burnley Corporation propose to purchase a 750-kw. steam generator and a motor-driven centrifugal pump. Estimates have been prepared in connection with the proposed new generating station at Bury, the total expenditure being estimated at £39,881, £48,155, and £55,720, according to the initial capacity of the works. The Tramways Department of the Glasgow Corporation invite tenders for two movable bridges over the Clyde Canal. Stores are required by the Electricity or Tramways Department of the following authorities:—Blackburn, Gravesend, Halifax, Leeds, Bermondsey, Battersea, Hammersmith, Islington, Portsmouth, and Sheffield. Electric lighting installations are required by the Burnley Union, at a number of depots in Hornsey, and by the Hull Education Committee. (Pages 215 and 216.)

The report of the City & South-London Railway for the half-year ended December 31st shows a net profit of £49,619. The full dividend on the 5 per cent. preference shares is declared, and $1\frac{3}{4}$ per cent. upon the ordinary shares. The Great Northern & City Railway Co.'s accounts for the December half-year show a balance of £379, which it is recommended shall be carried forward. The net balance available for distribution by the Liverpool Overhead Railway Co. is £9,105, and dividends of 5 per cent. upon the preference shares, and $\frac{1}{2}$ per cent. on the ordinary shares, are declared. (Pages 217 and 218.)

The problem of diminishing the light load losses in alternating current transformer distribution systems has been before the electrical engineer ever since the transformer itself has been applied for electric lighting. It would, in fact, be interesting to know the exact amount of energy which has been employed in carrying the iron cores of transformers round their cycles of magnetisation, and has served no more useful purpose than to maintain a high sub-station temperature. It is evident that the problem of lessening this waste is a harder one than appears at first sight, for during the last ten or twelve years quite a number of attempts have been made with only limited success to construct a practical and reliable device for automatically switching transformers in and out of circuit according as the load increased or decreased. We are able to give a description this week, however, of a method introduced by Mr. A. F. Berry a few years ago, the use of which is spreading in a way which indicates suitability to its purpose. One of the interesting points in the system is the way in which, by connecting the small transformer, which is used at times of light load, in series with the main transformer, all actual breaking of the circuit by the automatic switch is rendered unnecessary, and at the same time the voltage surgings and consequent shocks to the insulation, which are apt to be produced when a transformer is suddenly thrown into circuit, are avoided. A further advantage of the periodic rests to which the transformers are subjected is that, not only are the circumstances more favourable as regards the life of the insulation, but the same transformer can be used for a higher maximum load than it would be suitable for if not allowed to cool at intervals. Another result attained is the improvement of the voltage regulation of the network. As we have said, the use of the Berry "series" transformer system is extending, but we believe that no complete description of it has yet been published, so that our readers will welcome the detailed article on the subject, which we are able to offer them this week.

We have awaited with much interest the publication of the report of the Board of Trade inquiry, conducted by Major Pringle, into the West Hampstead accident. It had been thought fit to withhold the report until the conclusion of the criminal proceedings, which resulted in the acquittal of the signalman on the charge of manslaughter, and it is striking to note how different is the firm tone of Major Pringle's pronouncement from the conclusion arrived at by the judge and jury. The Board of Trade inspecting officer has no hesitation in declaring that "the collision was caused by forgetfulness, in the first instance, and subsequently by some illegal manipulation of the electrical instruments or locking" on the part of the signalman, who "must bear the full responsibility for his conduct." It is distinctly to be regretted that, while the engineering and legal aspects of the occurrence had to be investigated by separate tribunals, some form of collaboration could not have been arranged. If Major Pringle's clear report and well-considered conclusion had been available to assist the judge in his summing up and the jury in their verdict in the manslaughter trial, they would not have given the negligent signalman the benefit of the doubt which the decisive pronouncement of the Government's railway expert would have dispelled.

Now that the session of Parliament has actually commenced, and the season of companies' meetings and reports is also upon us, more information is available with regard to the intentions of the London electricity supply authorities and the promoters of the electricity Bills which will soon come up for consideration in the House of Lords. It appears that the proposal that is being brought forward by a new company is attracting far more attention than it was a month ago, when the scheme to consolidate the London companies under one management, and to work them by a joint committee, seemed to be the one of leading importance. It is now known that the engineers to the London & District Electricity Supply Co. are Mr. H. F. Parshall and Mr. Robert Hammond, who were both experts retained by the London County Council last year on the London County Council Electric Power Bill. The engineering details of the scheme are, of course, not yet available for publication, but it is freely rumoured that the general technical lines of design will bear a marked similarity to those of last year. This is, in fact, to be anticipated, as one would naturally not expect a radical change in Mr. Parshall's and Mr. Hammond's views in twelve months. As in the case of Mr. Merz's famous Bill of 1905, the chief interest in the first instance centres around the low rates at which supply is to be provided. The price offered for untransformed high-pres-

Digitized by Google

sure current supplied to authorised distributors is even less than in the London County Council Bill of last year, viz., £3 per annum per kw. of maximum demand, *plus* 0·25d. per unit, as against £3 15s. per kw., *plus* 0·22d. per unit. For transformed alternating current, £3 10s. per annum per kw., *plus* 0·3d. per unit, is set down, compared with £4 7s. per kw., *plus* 0·25d. of last year, and for direct current, £4 10s. per kw., *plus* 0·33d. per unit, instead of £5 12s. 6d., *plus* 0·27d. per unit. These prices may further be compared with the maximum of £5 per annum per kw., *plus* 0·5d. per unit, scheduled in the Bill proposing a combination of existing supply undertakers. As to supply to private consumers, there is a clause which will give rise to much discussion and opposition on behalf of the existing supply undertakers in London, and it will certainly puzzle the members of the Committee at the outset, unless it is very clearly interpreted to them. The company ask for power to supply any private consumer whose maximum demand is over 250 kw.; if the demand is less than 250 kw., they ask for power to supply, if they can do so, at a price lower by a certain percentage than that at which the authorised distributor is ready to supply. This percentage is 1 per cent. for every 10 kw. that the maximum demand is less than 250 kw. That is to say, that if the authorised distributor were willing to supply power to a consumer with a maximum demand of 50 kw. at a flat rate of 1¼d. per unit, the new company would be allowed to furnish the supply direct to the consumer at any price less than 1d. per unit.

The scheme to consolidate all the electricity supply companies under one management, known as the London Electric Supply (Joint Committee) Bill, will be the subject of opposition on the part of all the London Local Authorities, who apparently do not desire to avail themselves of the invitation to come into the Joint Committee which it is proposed to form. We are also in a position to state that a strong group of West-end companies, whose electric lighting business is likely to remain of far greater importance than their power load, is also opposed to the scheme. The companies who are promoting it are the Charing Cross Co., the City of London Co., the County of London Co., the London Electric Supply Corporation, the Metropolitan Electric Supply Co., and the South Metropolitan Electric Light & Power Co., and, in addition to these six companies, who will guarantee the interest on the capital of £1,000,000 that is to be issued if the Bill passes, two others, the Brompton & Kensington and the Chelsea companies, are also on the list of subscribers. As will be seen, the Kensington & Knightsbridge, Notting Hill, St. James's & Pall Mall, and Westminster Cos. (together with the Central Electric Supply Co.), are not taking active part in the scheme. It has been known for some time past that they are promoting a Bill of their own for a closer combination of their interests than is possible under their present Provisional Orders and Special Acts, but we believe that we are right in stating that they are actually opposed to the principle of the formation of a Joint Committee for the control of all of the London companies. It is easy to recognise that their interests are different to those of the larger companies operating further to the East and South, where the power load is of greater importance, but yet it is to be regretted that there is not a unanimity among all the companies working in London, for without that there will be little chance of any step being taken that will materially cheapen the cost of electricity supply in the Metropolis. That this supply is, on the whole, cheaper than in other large capitals we freely admit, but this is no reason why further economies could not be realised if the companies were placed in a more satisfactory position as regards ultimate purchase when their present concessions expire, for which probably they would be ready to guarantee a reduced tariff as a *quid pro quo*.

There is another element that has so far not been considered in the matter, viz., the attitude that will be taken by the Board of Trade. Mr. LLOYD GEORGE now knows more about electric lighting matters than when he made his statement of the Government policy with regard to the London County Council Electric Power Bill in 1906, and he has shown, in other directions, that, in matters in which the conciliation of conflicting interests is involved, he believes in the Board of Trade playing an active rather than a passive part. It would cause us no surprise, therefore, to learn that the question of electricity supply in the Metropolis will be relegated to a Royal Commission or Select Committee once more, or else that the present Bills are simply suspended to make way for a Government measure. In view of the new constitution of the London County Council, and the outlay which that body will incur on its new Municipal Building, the recommendation of the Hybrid Committee of 1906 to the effect that the Council should be the central electric supply company in London is hardly likely to be acted upon.

ARRANGEMENTS FOR THE WEEK

TO-DAY (THURSDAY), FEBRUARY 6TH.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at the Institution of Civil Engineers, Great George Street, Westminster. Paper to be read:—"Protective Devices for High-tension Transmission Circuits," by J. S. Peck.

Institution of Electrical Engineers: Leeds Local Section.

8 p.m. Smoking Concert at the Hotel Metropole, Leeds.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London. Paper to be read:—"The Present Position of X-Ray Measurements," with demonstration of apparatus, by Dr. Deane Butcher.

FRIDAY, FEBRUARY 7TH.

Institution of Civil Engineers: Students' Section.

8 p.m. Meeting at 25 Great George Street, Westminster. Paper to be read:—"Electric Hardening and Annealing Furnaces," by P. T. Steinthal. Mr. James Swinburne, F.R.S., will take the chair.

SATURDAY, FEBRUARY 8TH.

Junior Institution of Engineers.

6.30 for 7 p.m. Anniversary Dinner at the Hotel Cecil, London.

TUESDAY, FEBRUARY 11TH.

Physical Society.

7 p.m. Dinner at the Hotel Cecil, Strand.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting in the Municipal School of Technology, Whitworth Street, Manchester. Paper to be read:—"Electrical Driving of Textile Mills," by W. Hanna.

Institution of Electrical Engineers: Glasgow Local Section.

8 p.m. Meeting at 207 Bath Street, Glasgow, when the discussion on Mr. J. F. C. Snell's Paper, "The Cost of Electric Power for Industrial Purposes," will be continued.

Digitized by Google

WEDNESDAY, FERUARY 12TH.

Institution of Electrical Engineers: Birmingham Local Section.

7.30 p.m. Meeting at the Birmingham University. Papers to be read :—(1) "Experimental Determination of the Losses in Pole Shoes, due to Armature Teeth," by T. F. Wall and S. P. Smith; (2) "The Reluctance of the Air Gap in Dynamo Machines," by T. F. Wall.

Institution of Electrical Engineers: Students' Section.

7.30 p.m. Meeting at 92 Victoria Street, Westminster. Paper to be read:—"Train Lighting," by G. H. Nelson.

Association of Engineers-in-Charge.

8 p.m. Meeting at St. Bride's Institute, Bride Lane, Fleet Street, E.C. Paper to be read :—"Superheated Steam," by T. Sugden.

THURSDAY, FEBRUARY 13TH.

Rugby Engineering Society.

8 p.m. Ordinary Meeting. Paper to be read :—"Mechanically-propelled Commercial Vehicles, with Special Reference to the Petrol Electric System," by Bernard Hopps.

FRIDAY, FEBRUARY 14TH.

Northampton Institute Engineering Society.

5.45 p.m. Meeting at the Institute, Clerkenwell, E.C. Paper to be read :—"Some Problems of Electric Railway Operation," by E. V. Panell.

Physical Society.

8 p.m. Annual General Meeting at the Royal College of Science, Imperial Institute Road, South Kensington.

SATURDAY, FEBRUARY 15TH.

Institution of Electrical Engineers: Students' Section.

10.30 a.m. Visit to the National Physical Laboratory.

LONDON COUNTY COUNCIL TRAMWAYS

IN a report to the Council, the Highways Committee proposes to include among the tramway works to be put in hand during the year 1908-9 the electrification of the remainder of the London Southern Tramways system. This system was purchased by the Council from the London Southern Tramways Company by agreement as from October 2nd, 1906, and statutory authority for the conversion of the lines to electric traction is conferred upon the Council by the London County Council (Tramways and Improvements) Act, 1907. The reconstruction for electric conduit traction of a portion of the tramways, namely, the lines from Vauxhall to Brixton, is already in progress. The Act provides for the use of overhead electric traction on the remainder of the lines, and authorises the construction of certain single loop lines and the execution of street widenings along the route. The tramways are situated practically wholly in Lambeth, and the Act provides that the Lambeth Metropolitan Borough Council shall contribute one-third of the cost of the street widenings, but only on condition that the reconstruction of the tramways is completed by October 1st, 1909. It is, therefore, of importance that the remainder of the work should be proceeded with at as early a date as possible. The length of the tramways now proposed to be dealt with is about 1¼ route miles, and the estimated cost of the reconstruction and equipment of the lines for the overhead trolley system of electric traction is as follows :—Trackwork, &c., including special work and £4,600 for rails, £26,600; cables, cable-ducts, &c., £2,000; overhead equipment, £3,160; rolling stock, £3,150; total, £54,910. The Finance Committee, in agreeing to these proposals, point out that the cost per mile of single track for the trackwork and overhead equipment, viz., £11,904, is higher than in other cases of overhead construction, but special circumstances in connection with lowering roads under several railway bridges render this extra expenditure necessary. Under the Standing Orders, the consideration of this matter has been adjourned for a week.

In a further report the Highways Committee state that tenders have been received for the execution of the roadwork and platelaying, exclusive of the supply of rails and special trackwork, in connection with the reconstruction, for the underground conduit system of electric traction, of the existing horse tramways (i.) from King's Cross, *via* Caledonian Road and a short portion of Camden Road, to Holloway Road, and (ii.) from Holloway Road, *via* Seven Sisters Road, to Finsbury Park. The total length of line affected is about 2¾ miles of double track. The amounts of the tenders are as follows :—Dick, Kerr & Co., £53,516 15s. 10d.; Robert W. Blackwell & Co., £55,013 5s. 10d.; W. Manders, £56,684 7s. 4d.; J. G. White & Co., £58,249 14s. 3d.; John Mowlem & Co., £59,007; Edmund Nuttall & Co., £59,917 1s. 2d.; W. Underwood & Brother, £61,240 14s.; William Griffiths & Co., £62,041 16s. 7d.; William Muirhead & Co., £62,110 11s. 2d.; the National Electric Construction Co., £64,993 11s. 2d.; George Law, £68,489. The chief engineer's estimate, comparable with the tenders, is £58,986 16s. 2d.

The tender of Dick, Kerr & Co., Ltd., amounting to £53,516 15s. 10d., is recommended for acceptance, conditional upon their agreeing to give preference in employment on casual or unskilled labour required for the work to men *bona fide* resident in the county of London. Messrs. Dick, Kerr & Co. have intimated their willingness to adopt this course. A sum of £7,000 is included in the tender for alterations of pipes, mains, &c., the cost of which cannot be more accurately estimated beforehand, and also for any other contingencies which may arise. Messrs. Dick, Kerr & Co. are to be allowed to sublet to the undermentioned firms (or to such other persons or firms as may be approved by the chief engineer under the contract) the following portions of the work, namely (i.) to the Anderston Foundry Co., Ltd., or Wilson, Pease & Co., Ltd., the supply of the yokes; (ii.) to Doultons, Ltd., or Buller's, Ltd., the supply of the insulators; (iii.) to Bayliss, Jones & Bayliss, Ltd., the supply of the tie bars, bolts, &c.; and (iv.) to the Associated Portland Cement Manufacturers, Ltd., the supply of cement. The report was adopted at the meeting on Tuesday.

Cable Communication in the West Indies.—The Legislative Council of Trinidad has expressed its willingness to consider the advisability of increasing its subsidy for the Colony's cable service by £1,000 per annum in order to assist in procuring the establishment of an all-British cable communication from Great Britain, via Canada and Bermuda, to Barbadoes, Trinidad, and British Guiana, provided that the Legislatures of the Colonies of British Guiana and Barbadoes also express their willingness to do the same

Overhead Telegraph Wires in London.—On Tuesday last, in the King's Bench Division of the High Court, Mr. Justice A. J. Lawrence, the Hon. A. E. Gathorne-Hardy, and Sir James Woodhouse had before them the case of the Postmaster-General *v.* The Metropolitan Borough of Woolwich, which came up on an appeal from the award of the Stipendiary Magistrate for the Woolwich district. (*See* ELECTRICAL ENGINEERING, Vol. II., page 251.) Sir Robert Hunter, for the Postmaster-General, in presenting the case, explained that these wires were to be put up to connect alarms with fire brigade stations, but ultimately, no doubt, they would be used for telephone purposes. He estimated that were the work to be carried out in the manner proposed by the Borough Council, an excess in expenditure of £220 would be incurred. Mr. Thomas Edward Drucke, estate agent, said that iron poles did not deteriorate the selling value of the property. Mr. James R. Dickson, Borough Engineer, Woolwich, gave evidence as to the lasting value of an iron pole over that of a wooden pole. He was of the opinion that the work, if carried out according to the Postmaster-General's plans, would affect certain residential areas. Several other witnesses were heard, and the case was adjourned.

Preferential Charging Refused in Marylebone.—Sitting in the King's Bench Division of the High Court on Wednesday and Thursday last week, Mr. Justice Phillimore and Mr. Justice Walton heard an appeal against the decision of Judge Selfe in the Marylebone County Court in July last, in which certain Marylebone residents had failed to obtain a reduction of their electric lighting accounts in circumstances which certainly constituted a hardship. Messrs. Pemberton & Clark, a firm of auctioneers, occupied premises which were originally in the Hampstead electric lighting area, and in 1905 they entered into an agreement with the Hampstead Borough Council for the supply of electric light for a period of ten years at the rate of 4d. per unit. The Borough of St. Marylebone in March, 1906, advised Mr. Pemberton that, under the London Electric Lighting Areas Act, 1904, Messrs. Pemberton and Clark's premises had been transferred to the Marylebone lighting area, and they sent him a form to fill in whereby he would agree to pay for electric light at the increased rate of 8d. per unit for the first 200 hours of maximum demand per quarter, and 1d. per unit after. Mr. Pemberton declined to do this, and the Marylebone authority again wrote and asked him if it was his desire to be disconnected. He replied again that he wished to be supplied according to the terms of his contract with the Hampstead authority. The Marylebone Borough Council continued to supply him, however, and sent in accounts each quarter, made out on their basis of charge (8d. and 1d.), and in return a cheque was sent by Mr. Pemberton, not for the sum claimed, but for the amount due on the basis of 4d. per unit. Action was then taken by the Council for the recovery of the balance in the County Court. The Council had raised their meter rental, which was also in dispute. It was contended on behalf of the Marylebone Borough Council that they had simply charged according to the rates obtaining throughout the borough, and that no preference could be made. Similar applications to Messrs. Pemberton and Clark's were made by Mr. R. J. Knox, Messrs. Myring & Co., and Mr. Sobocuiski, all of whom were residents in Hampstead. After legal arguments by Mr. McMorran, K.C., and Mr. W. Cave on behalf of the Marylebone Borough Council, and Mr. Abinger for the consumers, judgment was given against the appeal, with costs.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

Draft Home Office Regulations

A SPECIAL general meeting of the Incorporated Municipal Electrical Association was held on Tuesday in London to receive a report from the Council upon the draft regulations issued by the Home Office under the Factory and Workshops Act, 1904, for the generation, transformation, distribution, and use of electrical energy.

Mr. S. L. PEARCE (Chief Electrical Engineer to the Manchester Corporation, and Senior Vice-President of the Association) presided in the absence of the President, Mr. H. Talbot (Nottingham), through illness. Mr. Pearce said that directly the Home Office issued the draft regulations above referred to, the Association was circularised, and the replies were dealt with at great length by a sub-committee, with the result that 41 formal objections had been lodged with the Home Office. The President (Mr. Talbot) and the honorary Secretary (Mr. Faraday Proctor) had had an interview with the Electrical Adviser to the Home Office, and although the result was satisfactory to a large extent, it was deemed necessary that some action should be taken towards being represented at the inquiry which was to be held by Mr. James Swinburne in March. Negotiations had been carried on with the Association of Municipal Corporations, and the question to be decided was whether the Incorporated Municipal Electrical Association should be represented at the inquiry independently or whether it should join forces with the Association of Municipal Corporations. In the first place, the following resolution would be put to the meeting: "That the Association of Municipal Corporations be informed that the Incorporated Municipal Electrical Association is willing to take joint action with them with regard to the employment of counsel and to tender expert evidence, it being understood that the objections raised by the Incorporated Municipal Electrical Association form part of the instructions to counsel." This resolution was proposed by Alderman Bruce (Sunderland), and seconded by Alderman A. Coates (Hanley), and carried unanimously.

Further resolutions were then put to the meeting, the Chairman explaining that they were contingent upon the first one, and were proposed in order to leave the Council absolutely prepared to meet any emergency.

(1) "That in the event of joint action by the Association of Municipal Corporations and the Incorporated Municipal Electrical Association not being arranged, the Incorporated Municipal Electrical Association proceed independently."

(2) "The President, the immediate past President, the senior Vice-President, the hon. Solicitor, and the hon. Secretary, form a sub-committee, with power to act, and to retain counsel if desirable."

Both these resolutions were carried unanimously.

After a short discussion, it was decided that any expense incurred should be provided by the municipalities forming the Association on the basis of gross annual revenue.

LOCAL GOVERNMENT BOARD LOANS.

The meeting then discussed the question of Local Government Board loans in relation to the payment of wages of permanent employees out of capital. It will be remembered that the Local Government Board has recently insisted that the wages of permanent employees engaged upon capital work should be provided out of revenue. The Chairman said he regretted that since the annual meeting last year very little progress had been made in this matter, nor had the Council been able to obtain an interview with the Local Government Board. The Council, however, did not intend to relax its efforts in this matter.

Mr. FARADAY PROCTOR (Bristol) mentioned that at Bristol, after a good deal of agitation, they had been allowed to pay certain wages of permanent workmen out of capital to the extent of something like £4,000.

Councillor SPENCER (Halifax) said that their experience at Halifax had been to the contrary, although they were still endeavouring to get reinstated a sum of £1,019 for wages.

A number of other speakers suggested that the members of Parliament for the respective boroughs should be approached with a view to appealing to the Board of Trade. Mr. R. Birkett (Southend), however, thought that harm was likely to be done by worrying a Government Department too much, for he was quite sure, from his experience, that the matter was not being put on one side by the Local Government Board. Mr. C. C. Atchison (Rochdale) suggested that the members of the Association should collect together reports of proceedings at Local Government Board inquiries upon this point, in order, if possible, to provide precedents to be produced when they themselves applied for loans. Mr. Faraday Proctor (honorary Secretary) said he would be pleased to have such information, and would tabulate it for the use of the members. Mr. F. M. Long (Norwich) said he had found the Local Government Board inspectors quite reasonable in this matter when he had explained exactly what he did in the allocation of workmen's wages.

At the conclusion of the discussion the Chairman stated that the Council would consider the various suggestions made, and would continue to press the matter until they had arrived at some satisfactory solution.

THE SUPPLY OF ELECTRICITY BILL.

A discussion then took place upon the desirability of urging the Board of Trade to introduce the Supply of Electricity Bill at as early a date as possible. The Chairman stated that the Council had no information to give to the meeting, as the Bill promised for this session had not yet been published, and therefore they could not discuss its provisions. Mr. A. C. Cramb (Croydon) spoke strongly as to the need for putting the law with regard to hiring out of motors and fittings, opening show-rooms, the stand-by clause, &c., on a more uniform basis. It was an expensive matter, he said, to have to secure these advantages by means of special Bills, and it was high time that such clauses were introduced into a general Bill, and it could very well be done in the Supply of Electricity Bill. During the subsequent discussion mention was made of the circular sent out by the Hastings Corporation on this point, and to the reply by the Board of Trade that in drafting the Supply of Electricity Bill this session, a clause of this nature would be introduced. Mr. A. H. Shaw, of Ilford, also pointed out that the Associated Municipal Electrical Engineers (Greater London) had been informed to the same effect by the Board of Trade. Subsequently Mr. Cramb proposed a resolution that the Council be asked to set out the various clauses referred to, and urge upon the Board of Trade that they should be included in the Supply of Electricity Bill to be promoted this session. At the same time Mr. Cramb expressed his doubts as to whether any such Bill would be passed. This was seconded, with the suggestion that a deputation should wait upon the Board of Trade. The resolution was then carried unanimously.

ELECTRIC POWER LOADS IN SOME LARGE SHIPYARDS AND ENGINEERING WORKS

IN the discussion in Glasgow on Mr. J. F. C. Snell's Paper on the cost of electric power supply, Mr. J. Robertson (Engineer-in-Chief to the Greenock Municipal Electricity Works) referred to some figures which he had with regard to the demand of shipyards and engineering works in his district, and at our request he has sent us the actual figures in tabulated form. They are appended below :—

	Nature of premises..	No. of motors.	Total H.P. installed.	No. of men.	Annual units.	Maximum load H.P.	Ratio of maximum H.P. to Total H.P.	H.P. per capita. (Total H.P. ÷ No. of men).	Units per capita.
1.	Shipyard	27	543	400	176,051	268	0·49	1·36	440·1
2.	Shipyard	43	1156	1150	376,000	536	0·463	1·005	326·95
3.	Engine works	30	647	730	279,439	234	0·36	0·886	382·8
4.	Engine and boiler works.	22	528	400	222,586	302	0·57	1·32	556·5
5.	Engine works	9	155	150	132,977	134	0·86	1·03	886·5

With the exception of No. 3, where a few small steam engines still exist, electricity is used throughout. This accounts for the difference noticed in Column H.P. *per capita*.

ELECTRICAL DRIVING OF ROLLING MILLS

THE paper read by Mr. G. Hooghwinkel recently before the Sheffield Society of Engineers and Metallurgists on the driving of modern rolling mills was almost entirely devoted to electrical methods, although a few notes were given of direct driving by steam and gas engines for three high mills and reversing mills of the heaviest type, but it was remarked that all the smaller mills, such as small finishing mills and continuous rod-mills, could be better and more cheaply driven by electric motors, in most cases without an additional equaliser set, such as in the Ilgner, Westinghouse, or other systems.

The advantages and disadvantages which may be urged for and against electric driving for rolling mills were tabulated by the author as follows:—

Advantages.—(1) Constant and regular torque; (2) more reliable, less breakages of couplings, pinions, &c.; (3) less room, on account of absence of boilers, pipes, &c.; (4) easy adaption to mill; (5) easy and simple handling; (6) easy distribution by means of cables, instead of steam pipes or gas pipes; (7) advantages of centralising the power; (8) less labour; (9) lower fuel costs; (10) less oil and other stores; (11) use of gas engines of medium size in power station; (12) increased output due to higher speeds. *Disadvantages.*—(1) Less efficient, and wasteful speed regulation; (2) influence of the variations of the required power on generating station; (3) electric motors overload themselves until circuit breaks; (4) higher fuel costs than direct gas-engine drive; (5) high capital outlay.

A further advantage is the power control and checking, which is easily effected by means of the usual electrical instruments at any moment.

In dealing with the question of the power station, the author said that the power station supplying the mills might be gas or steam driven, and in the latter case coal or gas-fired boilers might be used; or the supply might be derived from a public supply station, which might be compared with the private station, except that it would have a better daily load factor, due to the influence of the diversity factor, and would generally be of somewhat larger capacity. The heavier capital charges, and charges for directorate, management, cables, &c., would, however, in his opinion be found to completely outbalance any advantages which might result from the better load factor and larger capacity.

Both with steam turbines and large gas engines, he continued, the economy does not increase proportionally after a certain output per unit is reached. The writer would put this economical limit at 2,000 kw. for steam turbines and 1,200 kw. for gas-engine sets. In both cases the price per unit will not be materially different, although in this country, as well as in Germany, the price per unit delivered to the mains is higher with the large power company than with large private power stations at collieries and steel works, and it is the writer's opinion that, as time goes on and the loads increase, the power companies will not be able to catch up with the private power plants at the works referred to.

On a recent tour in Germany the writer found that two large Westphalian power companies charged over 1d. per unit to the collieries in their district. Several large colliery power stations in Germany, and a few in this country (Powell Duffryn Company) produce their own power at from 0·3d. to 0·4d. per unit, including capital charges. As to the power stations using waste gases from blast furnaces, the first cost of the power station is at least 60 per cent. more. The cost of production, however, though lower than with coal-fired stations, is not as low as is generally put forward, on account of higher capital charges and special maintenance due to periodical cleaning, &c.

In some of the large South German gas-driven power stations the generating costs per unit are stated to be 0·25d. This figure may be taken as being perfectly well attainable. Much depends, of course, on the price of coal and the value placed on the waste gases. With coal at 6s. per ton, the writer has obtained 0·3d. per unit at a large colliery power station with a 40 per cent. load factor. Coal at steel works costs much more at the present time, and in view of the rising prices it is better to calculate with coal at 12s. per ton, and place a value of ¼d. per 1,000 cubic feet on the gases. This latter price is low, and only represents the price of cleaning, water, &c., and the capital charges on the cleaning plant, pipes, and cooling plant. The capital charges, however, are responsible for the second heaviest item in the generating costs, and in many cases it will be found to be nearly as economical to have a steam-driven power station with boilers fired with the waste gases, although the efficiency of the gas engine is over three times as great. With coal at a reasonable figure, a steam station of the outputs met with in large steel works is not so much less economical than a gas-engine station due to the smaller capital charges.

Some detailed estimates of the power cost for steam and gas-power stations were then entered into, from which it was contended that for medium size steel works power can be obtained at from 0·35d. as a maximum to 0·12d. as a minimum per unit, with 0·2d. as a fair average.

Mr. Hooghwinkel then passed on to a short description of various methods of electric driving. In the first installations with which the writer was connected, such as the Peine Steel Works, at Hanover, compound wound continuous current motors were used on account of speed variation and starting torque. The intermediate mills were driven by means of ropes or belts, and the motors, as a rule, were direct-coupled to the finishing mill, which requires most power. A high speed (300–400 r.p.m.), and therefore cheap, motor could be used, having a heavy flywheel pulley. Rolling mill motors, however, require a double speed regulation. Firstly, various standard speeds for rolling various materials; and secondly, a drop in speed is required in order to make the flywheel do its duty and give up stored energy with increasing load on the motor. The first condition is met by a shunt motor, but with this class of motor the maximum drop in speed is only 2 to 3 per cent., quite insufficient to induce the flywheel masses to give up their stored energy. A series winding is therefore added to produce this effect. Continuous current motors are still considered to have some advantages over three-phase motors, especially in connection with the auxiliary plant, such as cranes, rolls, &c. In later installations, however, especially in works where a large central station with power transmission existed, three-phase motors are being more extensively used because of their simpler and more compact construction. The speed variation for both purposes, which in this case is obtained by means of a resistance in the rotor circuit, however, causes losses proportional to the percentage of the speed variation. But it is also possible to vary the speed without losses by changing the pole connections. A third method is by the use of two motors each for a standard speed, assuring high efficiency for each speed. This latter method has been adopted at one of the new roughing mills at the Hildegarde Works, which are rope-driven from one end.

To direct-coupled motors for heavy bar or plate mills, separate flywheels are added by means of flexible couplings. The dimensions of these flywheels depend on the number of passes at the same time, and the duration of each pass. Heavy flywheels will therefore be found on mills where the material passes but once, or with short passes. In order to obtain efficient flywheel masses, mills of this kind, *i.e.*, plate mills requiring 1,000 h.p. normal, are driven by high-speed motors (200 r.p.m.) and rope-driven, the motor being coupled to a solid cast-steel flywheel, allowing peripheral speeds of 150 feet per second. A considerable number of mills have been equipped on this principle, and have been very satisfactory, both from the point of view of power consumption and equalising in the central station. If further equalising is required, *i.e.*, when rolling mills are on a power company circuit, the by now well-known Ilgner flywheel sets have to be added. This is, however, a costly addition, and, moreover, precludes the use of three-phase rolling-mill motors. Lately, however, the writer has been interested in a modified system of this kind, which allows of slightly smaller flywheel sets, which are in parallel with the principal motor. This allows of the equaliser being uncoupled in the case of defects in this part of the plant, so that the three-phase high-tension mill motor can be run directly from the mains. An electrical winding engine on this principle is being erected at a South Wales colliery on the writer's advice, so that further particulars as to the results will shortly be available. Generally speaking, the writer is of opinion that for continuous mills no separate flywheel sets will be required. However, on account of the higher peripheral speeds (over 250 ft. per second), it may in some cases be more advantageous to run two or more mills from one flywheel set, instead of installing a number of heavy flywheels (on account of lower speed) on each mill. An additional advantage in this case is the efficient speed regulation by means of variations in the generator field, doing away with all starting losses.

Rolling-mill motors have to be constructed in accordance with the very heavy demands made upon them. They must have a

Digitized by Google

reasonable clearance, and, in any case, substantial bearings. Their maximum load is, as a rule, two or three times the normal rating—more often three times. Their speed variation is, of course, governed by the requirements of the material to be rolled. The heavy duty of these motors, due to their exposure to sudden jerks, was at first considered a serious bar to their introduction by the steel works' managers, but it has been proved in actual practice that these jerks do not inconvenience the motor (if properly constructed and designed) more than the steam engine. As a matter of fact, these jerks do more harm to the mills themselves, and the usual safety device which protects the mill also protects the motor. It is, however, necessary to give especial attention to the insulation and mechanical protection of the rotor windings, and especially the end connections, in the same way as is now being done in turbo-generator work, for these jerks are nothing more than speed retardations in a very short time, and the resultant forces act directly on the revolving windings. The greater number of the continuous mill motors at present installed are of about 500 h.p. normal capacity, but some of the heavier plate mills call for much more powerful motors—ranging in some cases up to 5,000 h.p. The heavier and more modern mills are nearly all driven by three-phase high-tension motors. The two-motor equipment is advantageous when two or more fundamental rolling speeds are required, but the system of driving required in each particular case depends on so many additional circumstances, and each case should be considered on its own merits on competent electrical expert advice.

As to the financial results of the electrical driving of continuous rolling mills, it may be assumed that in most cases, with electric power at sufficiently low figures, as is now being obtained from large power supply companies and steel works power stations, including 12 per cent. for interest and depreciation, electric driving will prove to be the cheaper. Results published from time to time, *i.e.*, lately by the Dillinger Iron Works, in Luxemburg, have confirmed this forecast, just the same as electric driving for pumping, endless rope hauling, and other continuous and non-reversible processes prove cheaper if properly designed and executed. These last points have in many cases not been kept sufficiently in view, and the several failures can nearly always be traced to one of these causes. A great deal depends, however, on the price paid for the electrical power. The writer is of opinion, however, that reversing mills will even pay better if electrically equipped than non-reversing mills, because the steam drive for any reversing plant is much less economical. The writer has been closely connected with the development of the electric winding engine, which is more or less on a par with the reversing mill, although not nearly as difficult a problem, and holds that it pays better to wind by electricity than to drive a fan if power costs anything like 0·25d. per unit. As, however, this question of costs has been most frequently attacked with reference to reversing plant, the writer proposes to give a detailed estimate with costs in connection with the reversing rolling-mill drive. The best proof of the commercial success of electric driving of all non-reversing rolling mills is the number of installations. In Europe alone, the number of motors installed for medium and heavy mill work is 230, with a normal capacity of 190,000 h.p., and a maximum capacity of 410,000 h.p. Over 60 per cent. of this number are repeat orders.

The two principal points to consider in the design of electrical equipments for reversing mills are the quick starting and retardation of the rolls. In order to obtain this it is essential to reduce the forces due to the inertia of the revolving masses. In the first equipments, which are all on the direct-current system, the motor had to be divided into two or three units in order to obtain broader and more compact construction with less flywheel effect. A good steam rolling-mill engine can be brought up to speed in 1½ to 2 seconds. The electric motors at Hildegarde, although calculated to take four seconds, performed this duty in 2½ seconds. This difference is so small that, even with eight reversals per minute, the time lost is

not considerable. At the Illinois Steel Works, where a 30 in. two-high mill is driven by two 2,000 h.p. motors at 0 to 150 revs., reversing every four seconds, the average station load is only 30 per cent. of the maximum load of the mill motors.

The Ilgner method of combining flywheel compensation and Ward Leonard control is so well known by now that it is not necessary to go into details. Recently the writer had the opportunity of applying another method on much the same principles, but in parallel and not in series with the main motors, to an electrical winding engine. The results are, however, not yet obtainable, but the arrangement, which consists of a rotary convertor and separate flywheel generator in parallel, present the advantage of allowing the use of three-phase mill motors, and the possibility of cutting out the equaliser set in case of break down, without stopping the mill, and a power factor of unity. These advantages may or may not counteract the disadvantages of greater power consumption due to starting losses, but the results from the winding plant will soon give the necessary data in order to come to a conclusion on this point. In most cases, but by no means in all, the addition of an equalising system will be required, but the cost of such a system will be many times repaid by the smaller power consumption in the power station, and the lower first cost of the prime movers, which need only produce the average load (about 25 to 30 per cent.), instead of being calculated to take the maximum power requirements. The ideal facility of control without loss is perhaps the most striking advantage of the Ilgner system. This system requires, however, direct-current motors, which are limited to a certain extent, owing to commutation difficulties, inertia of the revolving masses, &c. The first drawback can be overcome by the use of commutating poles and compensating coils, and the second by the subdivision into two or three motors. The first plant had three motors, but in all the later installations two motors have been found to be better. The excitation is either compound or shunt. The same remarks apply to the construction of the flywheel dynamo, which is subdivided for the same reasons. The broad design of the driving motors and their relatively small diameters brings the inertia moments down to about the same as that of the steel gear wheels between steam engine and mill. The absence of this gear is one of the advantages of the electric drive. In addition to what has been said with reference to the non-reversible motors, extraordinary stresses and jerks in the direction of the shaft have to be provided against. The frame and bearings of such motors are therefore often made of cast steel.

In conclusion, the author gave some comparative estimates for a steam and electrically driven mill of large size which went to show that with about the same capital expenditure an annual saving of about £3,000 per annum could be obtained by the adoption of electrical methods. The table opposite gives details of some important rolling-mill installations.

DISCUSSION.

The discussion was opened by Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield Corporation), who complimented the lecturer on his Paper, which was full of practical and common sense information. He was generally in agreement with what had been said, and considered the figures had been given in a conservative spirit. Sheffield manufacturers had already grasped the fact that smaller plants could be more cheaply driven by electro-motors. Where 500 to 800 h.p. is required it would pay to put down plant and have a competent man specially told off to look after it, and make him responsible for the costs. Referring to driving by large gas engines, he was very much surprised at the amount of labour required to look after them in some of the Continental works, the cleaning also was a laborious and costly business. Twin-engines should always be used, as mentioned by the author. He was firmly of the opinion it would be more economical to put down an electrical power house and have only one spare set. He was in agreement with the author in advising the use of polyphase motors, and he did not consider high-tension motors any more dangerous than the ordinary transformers used in house lighting.

Mr. J. S. PECK (Westinghouse Co.) hoped the steel manufacturers would take some of the truths to heart and not let the Germans get ahead of them. He emphasised the fact that by electrical driving it was possible to know exactly what power was required and was being taken by any particular class of work. In driving three high mills it is necessary to slow down and this can easily be done with induction motors by inserting resistances in the rotor circuit.

Mr. ECKMANN (Manchester) criticised the author's figures with regard to the cost of the gas for driving gas engines, considering it too low. He also did not consider it a fair comparison when burning the blast furnace gases under the boilers; the proper place was in the engine. Referring to the advantages of electric driving, he agreed that a very important one was being able to know exactly how much power was being taken for each billet, as it was then possible to calculate the costs very closely and quote accordingly.

Mr. HOOGHWINKEL, in replying, was sorry the discussion had been so meagre. He had particularly desired to read the Paper in the heart of the steel industry, so that the subject might be fully discussed by those more intimately interested. He prided himself with only having quoted figures which could be fully substantiated by actual practice. Replying to a remark by Mr. Fedden, the load factor in a modern steel works was about 40 per cent., and in a colliery with which he was connected it was as high as 49 per cent. The actual works costs in some of the German works were from 0·25d. to 0·2d. per unit. The advantages of high-tension motors were largely in the superior construction of the switch gear and the smaller cables required.

YORKSHIRE ELECTRIC POWER CO.

THE report of the directors for the half-year ending December 31st, 1907, states that the company's business shows a steady and progressive improvement. The profit on the revenue account for the half-year amounts to £836 10s. 5d., as against a loss of £403 4s. 3d. for the preceding half-year. After payment of mortgage interest, the net revenue account shows a loss on the half-year of £139 2s. 11d., as against a loss of £1,211 3s. 9d. for the half-year ending June 30th, 1907. The loss made in the half-year occurred during the earlier part of that period; during the last three months the receipts have not only met all current expenses, but have been more than sufficient to cover mortgage interest in addition. The demand for energy from the company's mains is steadily increasing, and the directors anticipate with confidence profitable and continuous progress of the company's business for the year 1908. Up to December 31st last, agreements had been entered into with consumers for a total of 5,548 kw., being an increase of 2,426 kw. during the six months, which is a considerably larger increase than in any previous half-year. Amongst these new agreements is one with the "British Carbide Factories, Ltd.," who have leased for a number of years a portion of the company's land in close proximity to the generating station, and are now erecting buildings thereon in which calcium carbide will be manufactured on a large scale for the first time in Great Britain. They have contracted to take their supply of current from the company, and will be important consumers. A supply of energy is now being given to "Electrical Distribution of Yorkshire, Ltd.," in Farsley, Gomersal, Horsforth, and Liversedge, and a supply will also be given to the company in Calverley at an early date. During the half-year the Ravensthorpe Urban District Council have commenced to take a bulk supply of energy. The agreement with that Council, as in the case of the agreements with the Pudsey Corporation and the Mirfield Urban District Council, provides that the company may give a supply for power purposes direct to large power users. Terms have been arranged with the Brighouse Corporation by which they will close down their present generating station and will take their energy for tramway, power, and lighting services direct from this company. As the company has now reached the position of meeting expenditure out of revenue, the directors suggest that in future the general custom of electrical and industrial companies shall be followed and the report and statement of accounts issued to the shareholders yearly instead of half-yearly as hitherto. A resolution to this effect will be submitted for the consideration of shareholders at the meeting on the 18th inst.

The revenue account shows that generation and distribution expenses amount to £5,190 11s. 2d., made up as follows:—Coal and coal handling, £1,740 15s. 10d.; oil, water, and engine-room stores, £55 3s.; proportion of salaries of engineers and officers, shift wages, &c., £1,075 0s. 2d.; maintenance and repairs, cost of work done for consumers, and sundry expenses, £2.321 12s. 2d.; managements and general expenses amount to £1.266 11s. 10d., the items being rents and wayleaves, £36 13s. 9d.; rates and taxes, £55 15s. 1d.; directors' fees (travelling expenses), £15 9s.; salaries and managing engineer, secretary, clerks, canvassers, &c., £629 12s. 10d.; stationery, printing, and advertising, £128 1s. 9d.; telephones, postages, and general establishment expenses, £181 2s. 4d.; auditors of company, £10 10s.; law expenses, £160 9s. 10d.; insurances, £48 17s. 3d. The total expenditure is therefore £6.457 3s. The receipts amount to £7.293 15s. 5d., viz.:—Sale of energy, £4.836 10s. 7d.; rentals of meters and other apparatus, £43 6s. 6d.; work done for consumers, £2,331 14s. 3d.; transfer fees, 15s.; sundry receipts, £81 7s. 1d., leaving a balance to be carried to net revenue account of £836 10s. 5d. The interest

Digitized by Google

on mortgage amounts to £973 13s. 4d., making the loss already referred to of £139 2s. 11d.

The total capital expenditure during the half-year was £3,746 2s. 6d., as follows :—Buildings, £47 7s. 2d.; machinery, £126 6s.; mains, £1,331 19s. 9d.; transformers and motors, and meters and installations on consumers' premises, £2,203 19s. 1d.; electrical instruments, £11 18s. 5d.; furniture, fixtures, utensils, &c., £214 12s. 1d. The total expenditure to December 31st, 1907, is :—Land, £6,773 16s. 0d.; buildings, £21,296 9s. 1d.; machinery, £71,413 13s. 7d.; mains, £90,999 0s. 4d.; transformers and motors, and meters and installations on consumers' premises, £18,014 18s. 7d.; electrical instruments, £8,165 8s. 11d.; furniture, fixtures, utensils, &c., £1,327; making a total of £217,987 6s. 6d. To this is added the sum of £67,522 4s. 1d., costs of promoting special Act and formation and preliminary expenses incurred by the Yorkshire Electric Power Syndicate, Ltd., and allotment of 2,000 fully paid shares in consideration of services rendered as per agreement, making a total of £285,509 10s. 7d. The total capital issued to date is £298,750, consisting of 25,875 ordinary £10 shares and £40,000 mortgage, leaving a balance of capital account of £13,240 9s. 5d.

NEW POWER STATION AT SALT LAKE CITY

A DESCRIPTION of a new steam-driven generating station under construction at Salt Lake City, Utah, U.S.A., which will form an auxiliary to a group of four water power stations, is given in the *Western Electrician* (Chicago). The plant is designed for a capacity of 6,000 kilowatts in six units—four of 1,250 kilowatts each and two of 500 kilowatts each. A plan of the station is given in Fig. 1.

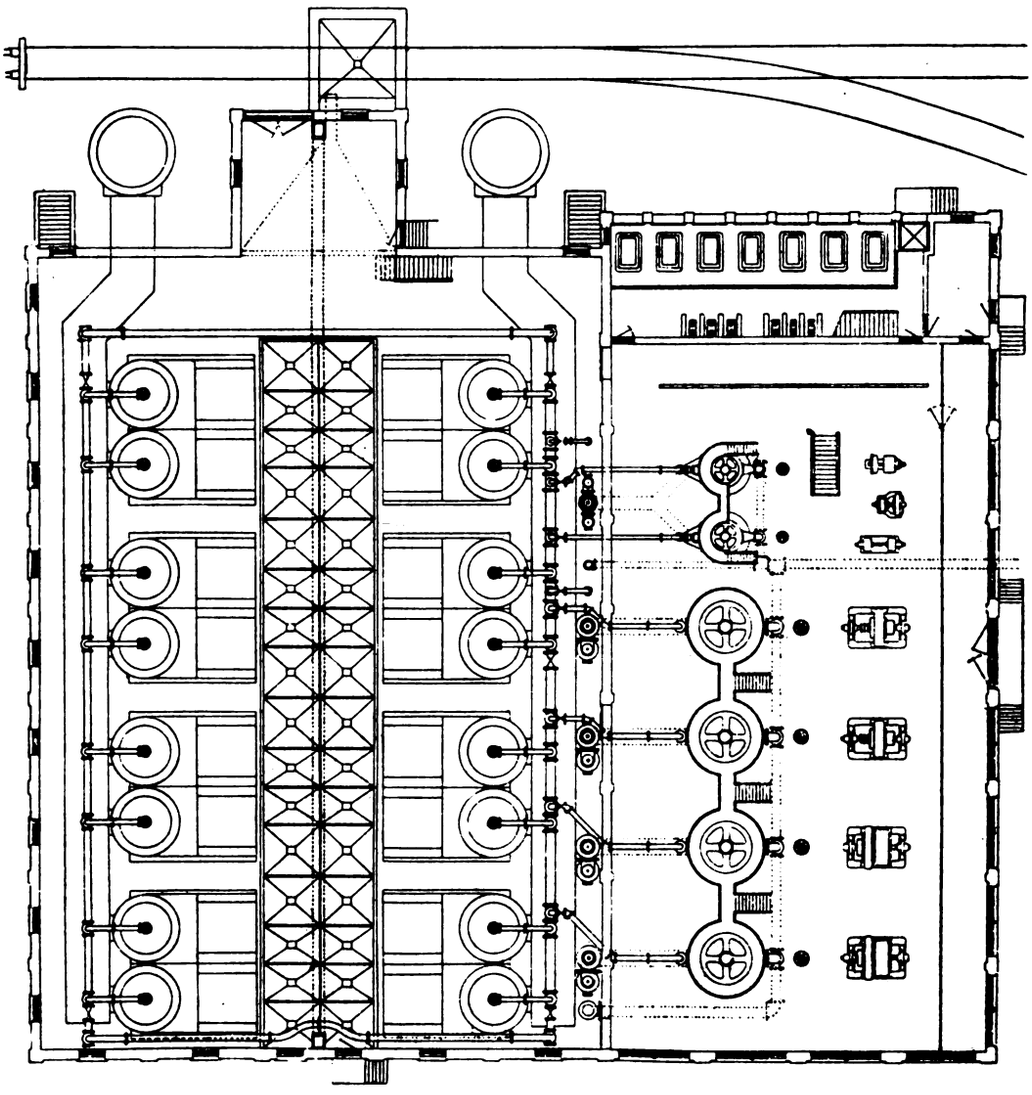

FIG. 1.—PLAN OF THE GENERATING STATION.

The boilers are of the Wickes water-tube type, which is a somewhat unusual pattern, with long, vertical straight tubes, set in two rows of eight boilers each, with two boilers in a battery. The rated capacity per boiler is 400 horse-power. Each boiler is equipped with a Murphy automatic furnace, and each battery is driven by a separate stoker engine. Natural draught is obtained by two reinforced concrete stacks, 200 ft. high. Each stack will accommodate one row of boilers, although they will be cross-connected for convenience in cleaning, &c. Each row of boilers is being equipped with its own feed-water heater and pumps, and when complete the heaters and pumps will be cross-connected, so as to obtain greatest flexibility. Space is left in rear of boilers for economisers, to be installed later. The boilers are designed for a working pressure of 175 pounds. On account of the company doing a public-heating business, the ratio of boiler horse-power per kilowatt is somewhat large, and also allows for the absence of superheating surface. The condensers are of the barometric type, and ordinarily supplied by steam pumps placed in the basement over cisterns into which are connected artesian wells.

A section showing the arrangement of the boiler is given in Fig. 2.

The present installation in the turbine room consists of a pair of 500-kilowatt, two-stage Curtis turbines, equipped with one motor-driven exciter and one turbo-exciter. One or two of the larger generators will follow immediately. For the direct-current power load a rotary converter will be installed, which, with compensator, will supply the 440-220 direct current. The generators are wound for 2,300 volts, three-phase, 60 cycles, and will run at a speed of 1,800 revolutions per minute.

The turbines are specially designed to operate in connection

Digitized by Google

with central-station heating, and will furnish exhaust steam at the required pressure from the first stage. The second stage is regularly equipped with condensers. The pressure from first stage leading to heating mains will be controlled with a special automatic reducing valve. The second stages of the 500-kilowatt turbines will be connected to a twin condenser of the Baragwanath manufacture. The first stages are connected into a common exhaust header, so arranged that the feed-water heater will float with the heating mains, and into this same header all the auxiliaries will discharge their exhaust. A combination back-pressure and relief valve is provided, both in first and second-stage exhaust lines.

The main switchboard, situated on the turbine-room floor, will consist of the regular generator, exciter, and feeder panels, together with the panels for receiving the current from the hydro-electric plants.

After leaving the switchboard, the feeder wires lead directly to a tunnel for general distribution, and the lines leading to high-tension apparatus lead directly through fireproof wall into special compartments. These compartments will contain seven 1,000-kilowatt, 33,000-volt transformers, the necessary oil switches for both the high and low sides of transformers, lightning arresters, disconnecting switches, coils, and a complete bus-bar arrangement for either one or two three-phase, 33,000-volt incoming circuits on either one or both banks of transformers. One spare transformer will be in readiness to throw into the circuit at any time without undue interruption in service.

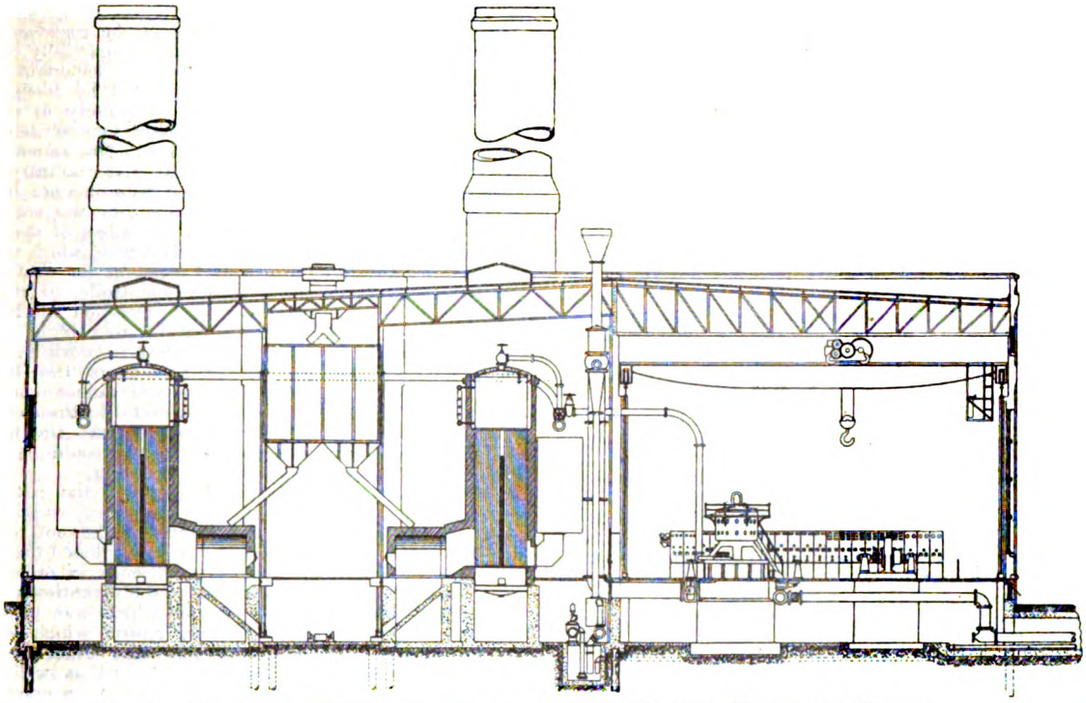

FIG. 2.—SECTION OF GENERATING STATION SHOWING VERTICAL WATER-TUBE BOILERS.

THE NEW PATENT LAW

MR. J. W. GORDON read a Paper on the new Patents and Designs Act before the Royal Society of Arts last week. He expressed the opinion that the language of the clause in the Act enabling procedure to be instituted for the revocation of a patent if it was not worked in this country was ambiguous if taken by itself. Thus he gives as an example the patent originally granted for the telephone and phonograph: "In these days the two instruments would probably be held to be different inventions, but when both were new the telephone, naturally enough, was regarded as a phonograph worked by electricity, and the phonograph as a mechanical telephone. Both instruments were comprised in one patent grant, but they gave rise to totally distinct manufactures. Would the fact that the one instrument might be mainly manufactured within the realm in such a case be held sufficient compliance with the Act, even although the other—the really important manufacture, suppose—was carried on exclusively abroad? If not, must the rule be applied distributively to all the separate claims made under a patent, and the patentee called on to show that his invention, in every separate application of it, is carried on mainly within the realm?"

"It is very difficult to see," the author continued, "if the language of the Act alone be considered, how this question should be decided. But when we know that the demand for legislation in obedience to which this Act was passed was a demand that every patentee should be required, subject to certain allowances, to perform the duty of introducing his patented improvement into the manufactures of this country, it becomes easy to decide between the two views. The real question, then, is not whether the major part of the work connected with the carrying out of a patented improvement has been done here or there, but whether the improvement itself in its entirety has or has not been fairly introduced into this country. If a patentee who by manufacture elsewhere has demonstrated his ability to bring his invention into use, shirks his responsibility so far as this country is concerned, that will be a good ground of revocation. While thus the principle may be identified with some confidence, it must be admitted that the Act will probably be a very difficult one to work. The criterion indicated—that of the preponderance of the manufacture carried on abroad—is one which affords but a very imperfect test of the matter which is essentially in question. There are very many manufactures, and with the spread of industrial enterprise over the whole world their number is daily increasing, in which it is impossible for this country to have a main share of the industry. Let me take by way of illustration the printing trade. That is one which is carried on by very elaborate mechanical appliances to the perfection of which a great deal of inventive industry has been recently applied and is being applied at the present time. Take the case of some valuable invention in connection with type setting or printing machinery. There is, of course, an enormous market for such an invention in this country; there is a market still larger in America; there is, it may be, a market larger yet on the Continent of Europe. Now, if the supposed invention is of sufficient importance and sufficient merit to make its way in all these different countries, it is not to be supposed that it could be mainly carried on within the United Kingdom. No patentee could be expected to bring about such a result as that."

No review of the New Patent Act would be complete without a reference to the question of compulsory licences, although, as is pointed out in the Paper, they were recognised in the Act of 1902, and the present Act only facilitates procedure in obtaining them. "The only tribunal," the author said, "which is favourably circumstanced for deciding upon the question of granting a compulsory licence in the High Court. The question of a compulsory licence invariably arises in connection with the question of the infringement of some specific patent. Now, as a rule, the manufacturer or dealer, as the case may be, proceeds

Digitized by Google

about his ordinary business in happy ignorance of the patent rights of other people. The small manufacturer cannot afford to spend the time necessary to make himself personally acquainted with the Patent Office file, nor can he afford the expense of keeping an expert staff at work upon the file for his information. He must, therefore, take his chance in patent cases, and he does. Every now and again it happens that he gets a threat of proceedings, and is warned to desist from some manufacture in which he is actually engaged. It is then that the question of compulsory licence arises in an acute form. It may very well happen that the manufacture which is the object of attack, is the result entirely of his own industry and invention. The effect which our law gives to patent rights, enables a patentee, in many cases, to exercise control over not only the industry which he may himself have created, but also, by means of what is known as a master patent, to enjoy rights in the tributary inventions and manufactures of other people. In the aggregate these tributary inventions, sometimes improvements upon a patented invention, sometimes themselves wholly independent inventions, form a very important branch of our manufacturing industry."

The author does not expect, however, that the chief effect of the provision relating to compulsory licences will be made manifest by actual litigation. The knowledge that such a remedy exists will incline both patentees and manufacturers to agree with one another, and to do by voluntary arrangement what they can be compelled to do by process of law.

The author next expressed the opinion that the clauses of the Act designed to prevent the imposition of oppressive conditions in the terms of licences had been drafted with very special care, and set out with great fulness and exactitude the precise intentions of the Legislature. At the same time, he added, an operation, even though skilfully performed upon so delicate an organism as the contractual relations of tradesmen and manufacturers with one another, must always be attended with risks, and perhaps the most it was possible to say at the moment about this provision was that it had been very carefully elaborated, with the object of preventing a very formidable mischief, and that both its practical importance and its theoretical interest would make the working of the system an object, for many years to come, of lively interest to all who are concerned in the working of our Patent law.

Dealing with the power to award costs, now for the first time conferred upon the Comptroller, Mr. Gordon pointed out that it was a new departure from the settled policy of former Statutes, and he criticises it for the following reason:—Opposition to the grant of a patent or amendment of a specification is based not usually on grounds of right, but on grounds of technical propriety. The patentee, for instance, who opposes a subsequent grant on the ground of a grant previously made to himself, does not by the result of his opposition, even if successful, in any way increase his own rights. On the other hand his action in a proper case does enable the Patent Office to exercise its powers with better discrimination than would be possible without such assistance. It is a public duty which the opponent fulfils, although he is usually animated in the performance of that duty by the expectation of securing some private advantage in the result. Now, it may indeed be said that it is quite right that a man performing a public duty should be secured against expense in doing so. But it is not equally easy to make out the proposition that the indemnity to him should be paid not out of public moneys but out of the private purse of the applicant for a patent. It is, of course, obvious that if the applicant is seeking some advantage to which he is not entitled, it would be reasonably fair that the necessary expense of restricting his claims to what is properly allowable should be charged to himself, but, on the other hand, he pays a sealing fee which is sufficient, on an average, to defray the expense of all the proceedings considered necessary at the Patent Office to secure the proper limitation of a patentee's claims.

Consideration of this question led the author to the matter of the search for anticipation instituted by the Patent Office, which, he said, resulted in the cost of a British patent being greatly less than that of obtaining a disputed patent in any other considerable country in the world. Patents of addition, however, were criticised, and the author found it difficult to understand their purpose.

DISCUSSION.

The CHAIRMAN (Sir William Preece) said that the Act did not meet the case where an applicant for a patent was bothered by some vexatious claim by somebody with an imaginary anticipation. There was a class of cranks, well known to patent agents, whose sole object appeared to be to lodge claims for priority on absolutely no justification whatever. They delayed the issue of the patent, and caused a great deal of trouble, as well as expense. If such people were promptly mulcted in costs, he thought the number of those vexatious appeals would be diminished.

Mr. WALTER F. REID, F.I.C., pointed out that very great power had been put into the hands of the Comptroller, and he hoped it would not be used in such a way as to countenance objections. It was well known, however, that some of the objections in the Patent Office to trade marks were absolutely childish, and if that sort of thing was to happen with regard to patents, the sooner another Act was passed doing away with the control of the Comptroller the better it would be. The author had, to illustrate one of his points, mentioned the utilisation of water-power for the fixation of the nitrogen of the air. It might interest him to know that water-power had not such a monopoly of the industry as had hitherto been supposed, because a large company would shortly be at work which would utilise coal for the same purpose, in the confident belief that coal, under certain conditions, could commercially compete with water-power. There was one extremely important reason why such a patent should not be controlled by foreign countries, but that the working should be compulsory in this country, viz., that England was at the present time entirely dependent for its explosives on foreign countries. Not an ounce of explosives could be made in England under the ordinary commercial conditions without using nitrate of soda obtained from abroad.

Mr. J. F. ISELIN said he was afraid he was not in harmony with the previous speakers as to the effect of the Act, which contained two important points. The first, which was the most important, was the forfeiture of a patent for want of working, and the second, the power of the Comptroller to refuse a patent altogether. A man who made an invention which was useful only to one manufacturer might be told if he went to the manufacturer, "You have no capital to work this invention; why should I pay for it? In four years' time the invention will fall into my hands, because you cannot work it in this country." Or, if the invention was useful to three or four manufacturers, they could form a ring against the inventor. He believed that exactly the same benefits could be obtained by means of a system of compulsory licensing.

Mr. H. FLETCHER MOULTON said, like the last speaker, he was considerably afraid of the compulsory working proposals, not because he thought the patents ought not to be worked in this country, but because the Act abandoned the very obvious and proper system of compulsory licence in order to try and force the starting of the working of the invention simultaneously in all the countries of the world, which was in most cases a practical impossibility. The only reason which could be suggested for such a procedure was that other countries were trying it, and that England might just as well be forward in the race; but it was perfectly impossible in practice to expect that a complicated invention, like the linotype machine, for instance, could be manufactured in three or four years in a dozen different countries. He very much regretted that, instead of trying to improve the machinery of the compulsory licence, it had been pushed to the background. The same remark applied to the clause dealing with restrictive covenants. The introducer of the Bill did not seem to realise that he was handicapping, not so much the patentee, as the person who wanted to get a licence under it, by saying that no licenses should be granted on the terms that all the machinery was to be taken from one particular man. He heard the Act described by Sir Joseph Lawrence at the Imperial Industries' Club as a layman's Act. The author and many others present remembered with gratitude other laymen's Acts, such as the Workman's Compensation Act, which had provided a very deserving class with their living for some years past, and he trusted the new Patent Act would have the same effect.

Cellulose Acetate as Insulation for Wires.—An article by Mr. R. Fleming in the *General Electric Review*, abstracted in the *Iron and Coal Trades Review*, deals with the suitability of cellulose acetate as an insulating covering for wires. The new material is claimed to have a high degree of elasticity and high specific resistance, and it is said that very even coatings can be applied to fine wires. It is particularly suitable for wires from No. 35 to No. 40 B & S gauge, and has been used with success for the windings of meter armatures. The thinness of the coatings, which for 0·003 in. diam. wire need not exceed 0·0005 in., as compared with cotton or silk insulation, renders a much better space factor obtainable. Another great advantage of acetate wire is that it is not affected by ordinary atmospheric conditions. Complete drying and impregnating processes are necessary for fibrous insulations, if long life is to be expected of them. In the Lynn acetate wire-coating machines the solution automatically passes from the mixing reservoirs to the coating portion of the apparatus. Here, by a system of transfer wheels, the solution is applied to the revolving coating roll, which, in turn, deposits it on the moving wire. The quantity of solution placed on the wire must be adjusted to a nicety; therefore, mechanical scrapers are employed, which remove the excess and leave just the proper amount to be deposited. After receiving its coating of solution, the wire passes through the oven at the rate of several hundred feet per minute. The volatile solvent is here driven off and the coating hardened, after which the process is repeated until numerous coatings have been applied. This method insures an even distribution of the film over the whole surface of the wire. To keep the fine wire moving at such a high rate of speed a very delicate adjustment of the moving parts is required, for the slightest unevenness of motion is sure to break the wire. This is prevented by friction drives and friction tension devices, which insure a uniform motion.

WATER-POWER STATIONS OF THE SOUTHERN POWER CO., OF AMERICA

IN a short note in ELECTRICAL ENGINEERING, January 2nd, page 24, entitled "Power Developments in South Carolina," we referred to the large water power scheme of the Southern Power Company being pushed forward in that district, partly to cope with the growing demand for electrical energy for textile factory driving in what is known as the Piedmont region. Some further particulars of the companies' undertaking are given in the *Electrical World* (New York). Electrical energy is now distributed to Charlotte, N.C., the company's headquarters, from the Catawba River, eighteen miles away, for operating street railways and for feeding lamp and motor circuits. Other towns in the vicinity where energy from the same source is available are Concord, Rock Hill, Kanapolis, and Statesville. The company charges $20 per horse-power per year for energy used 11 hours a day six days a week. Steam power, under most favourable conditions, is stated to cost about twice as much.

The Southern Power Company already has in operation two large electric plants, one called "Catawba" is rated at 10,000 horse-power, and the other, known as the Great Falls Plant, has a rated output of 40,000 horse-power. The company is now carrying out plans for the development of 200,000 horse-power. It controls nine separate sites in the Piedmont section, where rapids occur between the head waters and the lowlands over a distance of 110 miles in all, and with an aggregate fall of nearly 1,000 ft. A new plant, rated at 40,000 horse-power, is building at Rocky Creek, and another rated at 24,000 horse-power, is building at Ninety-Nine Island, near Spartanburg. Similar developments are planned at other points in the river.

Of the different power sites, controlled by the company, the one known as the "Great Falls" of the Catawba River offered the best opportunity for the initial development; so the work was begun here first. A railroad twelve miles in length was built to connect the Great Falls site with the railway centres of the State, and to furnish transportation facilities for material of construction.

Before development, the Great Falls comprised a series of falls and shoals having a total head of 176 ft. over a distance of eight miles, for the full utilisation of which three separate developments will be required. The middle one, with a head of 72 ft., and receiving the run off from a drainage area of 4,200 square miles, is known as the Great Falls Station, and has just been placed in service. It is located on one side of an island, known as Mountain Island. A low spillway dam was erected across the river at the head of the island to deflect the entire volume of the river into the western channel. Across the western channel near the foot of the island is built a 30-ft. spillway dam, this dam deflecting the water into an almost natural canal which carries it about 1¼ miles, at which point is located an enormous retaining wall across the natural valley. Built into this retaining wall are eight 5,200-h.p. hydraulic turbines of the twin horizontal type, enclosed in steel cases 15 ft. in diameter by 19 ft. long. Steel feeder pipes of 7-16 in. plate are encased in the retaining wall, these feeder pipes being elliptical in form at the intake; dimensions, 16 ft. × 18 ft., gradually narrowing down to 15 ft. in diameter where the feeder enters the wheel case. The draft tubes are also built of 7-16-in. sheet steel, and are 11 ft. in diameter at the wheel case, gradually increasing to the point of discharge, where they are elliptical in shape, 11 ft. × 18 ft. A special feature in this construction is a tunnel extending the entire length of the power house through the retaining wall and behind the turbine cases. By this method of construction the usual outboard water bearing is replaced by an oil bearing, which may be easily got at and inspected. This tunnel also makes it much easier to get at any part of the wheels when necessary. Both bearings are rigidly connected to the head, the outer bearing being designed to take up the end thrust of the wheels. The gates are of the swivel type, and so designed as to give the maximum efficiency at approximately three-quarter gate, which represents full load on the generators.

The two turbines for operating the exciters are similar in construction, and are rated at 700 horse-power at 450 r.p.m. under a working head of 72 ft. At the intake the feeders for the exciter turbines are 6 ft. × 9 ft., gradually tapering to 6 ft. in diameter at the wheel case. All feeder pipes are equipped with manholes and vent pipes. The draft tubes are 5 ft. 6 in. in diameter at the case, flaring out to 10 ft. in width at the discharge end.

The 5,200-h.p. turbines are direct connected to 3,000-kw., 60-cycle, three-phase, 2,300-volt generators and the two exciter turbines to 400-kw., 240-volt direct-current generators.

The switchboard is mounted on a gallery which stands about 6 ft. above the main station floor, thus giving ample space below for all cables, which are placed in racks on either side, the direct-current cables being on one side and the alternating-current cables on the opposite side. Behind the switchboard is the transformer house in which are placed four banks of transformers, each bank consisting of three 2,000-kw. oil-insulated, water-cooled transformers, which step up the potential to 44,000 volts. The transformer casings are designed to withstand a pressure of 150 lb. per square inch, and are equipped with relief valves connected to a vent discharging outside of the building. The transformers are mounted on flanged wheels, and stand in their respective compartments on rails supported on concrete pedestals. A pipe system through which carbon dioxide may be admitted in case of fire connects all the tanks. The gas generator and pressure tank are placed in the basement, and in addition to the transformer connections a pipe extends to the second storey so that any apparatus on this floor may also be deluged in carbonic acid gas in case of necessity. The oil for the transformers may be supplied by gravity feed or by a pressure feed from a tank outside. By reversing the direction of rotation of the pump the oil may be withdrawn from the transformers and, after passing through a filter, returned to the storage tank. Connections are also provided for discharging the oil into the tail race. An electrically-driven triplex pump supplies oil to the high-tension apparatus on the second floor of the transformer house through two pipe leads terminating in hose bibs in floor boxes.

Each generator is controlled through an instrument post and switch pedestal. Each post is equipped with an ammeter, voltmeter, wattmeter, and field ammeter, and in addition there are two synchronisers, two frequency indicators, and four bus-bar voltmeters distributed among the several posts. Each control pedestal is equipped with a remote-control switch for operating an oil circuit-breaker, one field switch, a rheostat hand wheel, an eight-point voltmeter receptacle, a meter shunt, and a lamp reflector.

The main switchboard contains two transformer panels, two double-circuit feeder panels, one station panel, and two blank panels. Concrete slabs are used in the low-tension bus-bar and oil switch structure, the cells in the sub-structure containing the oil switches and the busbars being housed in compartments above these. The bus-bars are cut into two sections by an oil circuit-breaker; and each section may be further divided by means of selector switches.

The high-tension transformer leads are taken through wells in the floor of the second storey, and connect through oil switches to the high-tension busses or feed direct to the line. The current for operating the high-tension circuit-breakers is obtained from oil-insulated series transformers. Oil-insulated choke coils are placed between the transformers and the oil switches to relieve the former of the strains due to surges in the line. Lightning arresters of the single-pole, low-equivalent type are installed.

Four sets of outgoing lines are used for distributing the energy, a double steel tower being used for supporting this line.

Besides the Great Falls station, the Southern Power Company has ordered six 5,200-h.p. and one 700-h.p. twin horizontal turbines, which will be exact duplicates of the Great Falls turbines for the new Ninety-Nine Island station. This station will be located on the Broad River nine miles above Blacksburg, S.C. Work is now being pushed on this development, and everything will be rushed as rapidly as possible to completion. The other developments will be taken up in order and completed as rapidly as possible. It is stated that when all of the developments of this company are completed they will have carried out not only the largest power scheme in the Southern States, but one of the largest in the world.

Electric Heater.—A new form of water-heater is described in the *Electrical World* (New York). The water circulates between two cylindrical carbon electrodes, the gap between which is from 1-8 in. to 3-32 in. The electrical energy is thus converted into heat energy directly in the water, and radiation and conduction losses are reduced to a minimum. When applied to a bath or wash-basin, the handle which turns off the water also opens the circuit. This form of heater has been successfully used in conjunction with hot-water radiators for heating purposes. The heater is made in various sizes, the largest being for 20 amperes at 220 volts, and the smallest for 4 amperes at 110 volts.

ELECTRICAL EQUIPMENT OF THE STUYVESANT THEATRE, NEW YORK

ONE of the most complete electrical equipments ever built for a modern playhouse has been installed in the Stuyvesant Theatre, New York. The interior illumination has been carried out in accordance with suggestions from Mr. Belasco, and is described in the *Electrical World* (New York) as restful and pleasing.

The stage is equipped with 84 arc and incandescent pockets, each of which is rated at 50 amperes. The pockets are placed in the stage floor, and in the floor of the spot-light gallery, erected for this particular purpose.

The entire lighting is controlled from a special stage switchboard, arranged so that all the switches can be controlled individually, collectively, or in any desired combination at will. The board is of slate, with the various operating levers, gang shafts, and sectional shafts mounted thereon. It is supported on a heavy, angle-iron frame about 2 ft. from the proscenium wall on the lighting bridge. The switchboard platform consists of a large slab of white marble, and is 12 ft. from the floor.

The dimmer handles and shafts are mounted directly above the board and can be manipulated similar to the switchboard section. The dimmers are of the Ward Leonard type, mounted above the stage switchboard, and are operated by means of steel rod drives.

A large distribution box is installed directly underneath the marble switchboard floor. It is divided into sections and provided with doors for the purpose of easily getting at the wiring. The wires in this box are tagged and numbered for convenience in making repairs quickly. The centre of distribution for the auditorium and stage lamps is under this box, so that should a fuse in any section or circuit blow, another can be easily inserted.

The stage arc lamp pockets are of the most recent type. A three-wire circuit is run to the main centre of distribution from each pocket and this circuit is protected by a 50-ampere fuse. The incandescent lamp pockets are similar in construction and wiring and are arranged with dimmers on each outside wire, so that one half of the section may be separately dimmed from the other half.

The lighting bridge is a special novelty, and on each side of the stage there are mounted eight 50-ampere arc lamp pockets, making a total of 16 for both sides, for the purpose of concentrating a powerful illumination upon the stage.

There are five borders, each consisting of 72 white, 60 red, 60 blue, and 65 amber incandescent lamps, all of 32 candle-power. There is also a large panorama border of 220 32-c.p. lamps, arranged in a semicircle. The border lamps are fed from a 48-strand flexible border cable carried in conduit from the main centre of distribution to the gridiron, whence the wires drop directly over each border, terminating in a splicing and pull box. Near the end of the pull box, each border cable is securely fastened on the steel border cable by means of a 2½-in. split wire grip laced in the centre so that it is impossible to pull the cable away from the splicing box. Specially designed sheave wheels are also provided for the purpose of having the slack constantly taken up, so that the raising and lowering of the cable will not in any way interfere with the scenery. This also guards the cable against mechanical injury. The borders are suspended from four large strain bolt insulators, secured to steel cables running up to the gridiron, so that they are perfectly insulated.

The double border strips have wires with slow-burning insulation. The wiring is so arranged that each border is divided in two sections. Consequently one half can be operated from the stage switchboard separately from the other half, in order to get the lighting effect desired.

The footlights are made up of four rows of coloured lamps, the number of which is approximately the same as in each border. Instead of the usual galvanised metal gutter, the lamps are wired in conduit with iron boxes, and so arranged that each circuit runs down to the apron of the wiring gutter which is about 32 ft. long, and is arranged with sliding covers for the purpose of getting at the different circuits, so that should a wire break through accident, or a short circuit be caused by mechanical injury, repairs can be made in a very short time. All circuits from this wiring gutter built in the apron of the stage terminate in the centre of distribution, and the main leads run to the main switchboard through dimmers, and are controlled in sections or all together. To the left of the board there is a five-compartment signal cabinet and the wiring is arranged so that when a push button is pressed underneath each lamp compartment, a lamp will flash at a distant point, and at the same time will indicate on the signal cabinet that the signal has been received, at the stage, each fly gallery, rigging loft, on the opposite side of the stage, or in the musicians' pit, as the case might be.

In addition there are speaking tubes and buzzers running to each of the above-mentioned points, should the signal cabinet fail to work. There are also mounted on the signal cabinet 24 buzzers for signals to the occupants of the dressing-rooms, and six chimebells distributed throughout the auditorium, lobby, &c., for the purpose of notifying persons there that the curtain is about to rise. The bell and telephone system is supplied by a motor-generator situated in the chief electrician's room, where the main meter and distribution board is also placed. The latter is a large marbleised slab switchboard with angle-iron frame and enclosed with steel sides and doors, and with a rolling shutter in front. There are five meters, eight motor-switches, and nine three-pole lighting switches mounted thereon. There are two 1,500-ampere main feeder switches, for the control of the entire circuits throughout the building, each of which is connected to a separate service from the illuminating company's mains. The 1,500,000-circ. mil feeder leading to the theatre board runs in iron conduit underneath the auditorium floor to the main centre of distribution behind the stage, where it connects with two sets of bus-bars. The "front-of-house" board controls 38 circuits for all exit, stairs, lobby, and front-of-house lighting, and this panel is supplied by a separate connection from the Edison company's service.

Perhaps the most novel and pleasing feature of the lighting scheme is found in the auditorium dome. There are approximately 400 incandescent lamps installed behind octagon-shaped art glass panels in the ceiling of the auditorium, the light being diffused through these panels.

The other lighting fixtures are for the main part of the concealed type, and in no case are the lamps visible in the auditorium. There are eight special column caps of glass in the auditorium of antique design, which have 36 32-c.p. lamps concealed in each. All balcony and box lamps are concealed in bowl-shaped fixtures of glassware of novel design.

The theatre is also equipped with inter-communicating telephones wired in iron conduit, with 34-strand special telphone cable.

In the basement of the theatre is installed a triplex, direct-connected, 25-h.p. fire pump, and a switchboard is installed for the automatic control of the motor. The motor is also provided with a hand starter, speed regulator, and a pressure regulator which starts the motor as soon as the pressure is below the requirements of the fire department; besides this there is a fire alarm system directly connected to the city fire-engine house.

For the heating and ventilating system there are installed an 84-in. blower which forces the hot or cold air to the auditorium, and a large exhaust fan in the dome of the auditorium, for the purpose of ventilating the entire house. The fans are direct-connected to motors of the enclosed type. In the centre of the stage is a large electric elevator for lowering all properties to the basement and sub-basement for storage. The elevator is equipped with controlling devices, and is provided with a mechanical safety clutch. The total travel is 32 feet.

Government Control of Niagara Electric Power.—It is stated that Mr. Steele, President of the Toronto Chamber of Commerce, has agreed to start a movement having for its object the Government ownership of the electric power plant at Niagara. It is claimed that the Falls would be safeguarded by such an arrangement, and that a better management of the plant in the public interests would also result.

The Indian Electricity Act.—We understand from an Indian correspondent that, owing to difficulties having arisen regarding the grant of powers to certain companies wishing to supply energy in bulk in India, a committee was formed in 1907 to make suggestions for the necessary amendment of the Indian Electricity Act, 1903. The committee found that in various other points the Act had either shown itself to be defective or would in course of time do so, and suggested a number of other amendments; and they also suggested that in place of the Act being administered by the local governments of the various provinces and administrations—over a dozen—it should, for the present, be entirely administered by the Governor-General in Council. Under the existing Act anomalies occur owing to a reservation regarding places in military occupation, which can only be licensed by the Government of India, whereas such areas may, and often do, exist in the middle of a town where a licence has been granted by a Local Government. Confusion is bound to occur in cases like this, and those who put money into the undertakings are apt to become alarmed. The various proposals of the Committee of Amendment have been submitted to Local Governments and Chambers of Commerce, and, so far as information is available in the Press, have met with very general acceptance.

THE BERRY SERIES TRANSFORMER SWITCH FOR SAVING LIGHT LOAD LOSSES

A NUMBER of attempts have been made from time to time to improve the overall efficiency of alternating-current distribution systems with transformer sub-stations, owing to the heavy "light-load" losses entailed by the all-day use of transformers of sufficient size to deal with the maximum or "peak" load, especially in the case of a purely lighting load. A method which has obviated some of the difficulties met with in earlier attempts, and has met with a good deal of success in this direction, is the "series system" designed by Mr. A. F. Berry. Although primarily devised with the object of minimising light-load losses, the use of the apparatus introduces, as we shall see hereafter, other advantages in the directions of improved voltage regulation, and the possibility of employing transformers of not only better design, but even smaller size for the same work than would be otherwise required. The conditions under which the transformers work are also more conducive to their long life.

Briefly, the general principle of the system is the provision in a sub-station of a small auxiliary transformer, so arranged with its primary and secondary windings in series with those of main transformer that it takes practically the whole of the load when light, but is cut out by an automatic switch when the load rises above a certain value. The scheme in its simplest form is shown diagrammatically in Fig. 1. This represents a sub-station with a single main 100-kw. transformer for 2,000/200 volts, and an auxiliary 10-kw. transformer. A little reflection will enable one to see that when the two are in series with the switches P and S open—as shown in the diagram—practically the whole of the voltage will be across the terminals of the smaller unit, owing to the relative impedances of the windings of the two. In such circumstances, therefore, the magnetisation cycles of the large transformer will be in that region of its curve below the steep part where hysteresis is practically non-existent. The small transformer will be taking such load as there is, and the magnetising current, which the station is called upon to supply, is only that corresponding to the 10-kw. transformer instead of, as would otherwise be the case, the 100-kw. unit.

When the load increases to an amount for which the capacity of the small transformer is insufficient, the relay solenoid, A, which, for convenience, is shown in two places in the diagram, in order to indicate its position both electrically in the primary circuit, and mechanically in the control apparatus, comes into action. It draws down the lever arm and causes the lower carbon contact, C_2, to close. This energises the lower coil, K_2, of the actuating magnet, M, so that the movable armature is raised, and the switches, S and P, closed, thereby short-circuiting the primary and secondary of the small transformer simultaneously. The whole load is then taken by the large unit in the usual way. As will be seen, the mechanical construction of the switch is such that, when once on, no further force is required to keep it closed, so that the current can be cut off from the operating coil as soon as the switch, S, is closed. For this purpose a rocking lever, R, is provided, carrying a carbon contact at each end. When the plunger rises, the left-hand contact shown closed in the diagram opens and breaks the circuit of the lower operating coil, while the right-hand contact switches in the circuit of the upper operating coil, ready for use when the time comes to open the switches. When the load falls to a value which the small transformer can deal with, the relay arm rises and closes C, energising the upper operating coil so that the switches S and P are pulled off. As soon as this is done, current is cut off from the coil by the lever, R, as before. It will be seen that, as the current is not kept on to the operating coil more than momentarily, a pretty strong current can be used without appreciable losses, so that the forces dealt with can be large, and the construction of the apparatus robust.

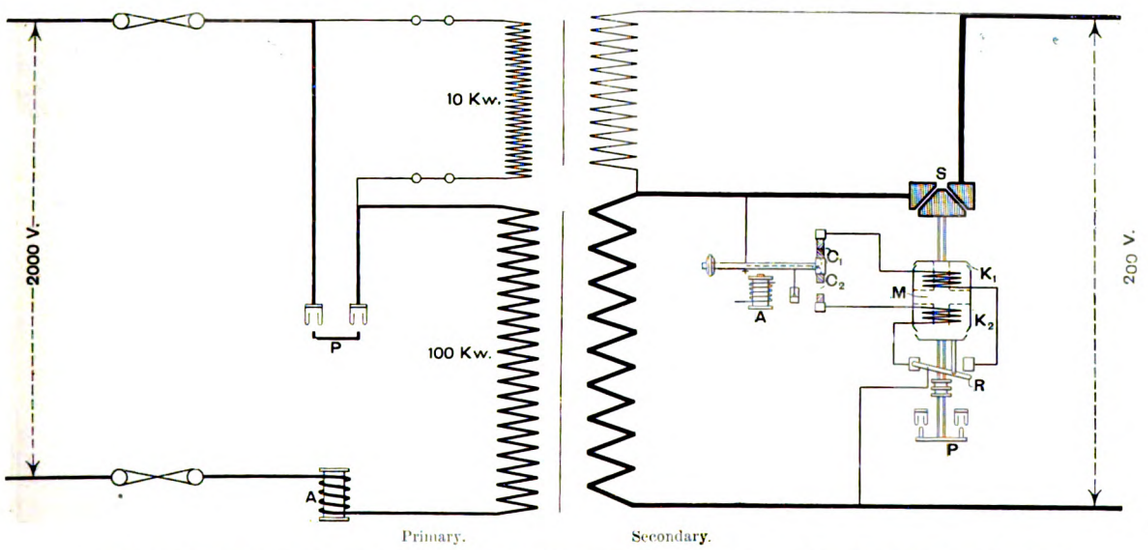

Fig. 1.—Diagram of Connections: Berry Series System for Two-wire Single-phase Circuit.

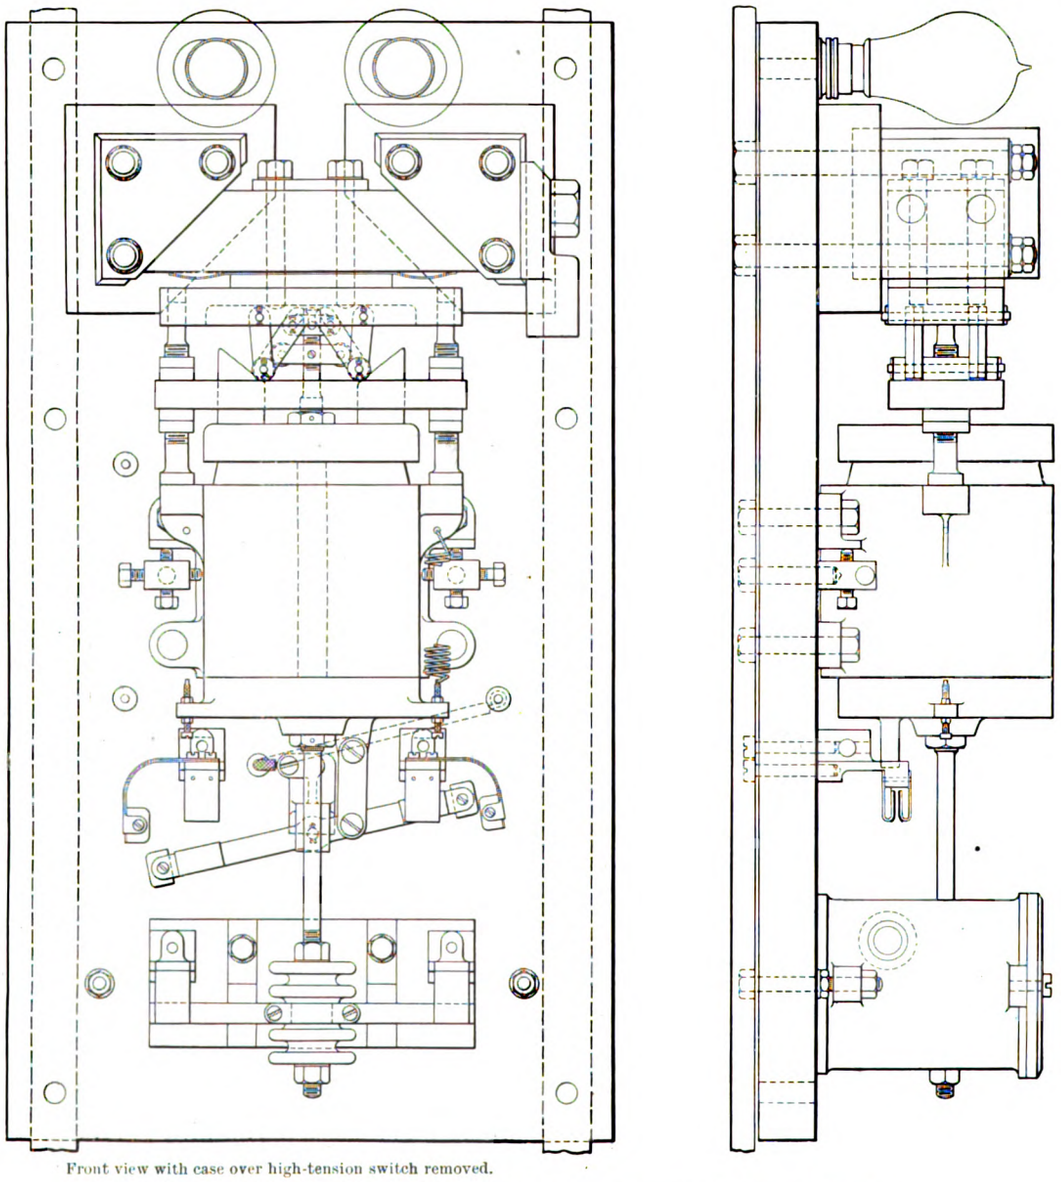

The representation of the control apparatus in Fig. 1 is, of course, only diagrammatic, but the form taken by the different parts of controlling gear is seen in Figs. 2, 3, and 4, which show respectively the details of a switch for an ordinary two-wire system, and control equipments for three-phase and single-phase three-wire circuits. In the latest form of the standard arrangement the switch mechanism is mounted on one panel, and the relay and fuses for the small transformer on another panel, which may or may not be placed alongside. The three-phase gear only differs from the single-phase form of the apparatus in having a three-pole

Digitized by Google

primary switch. In the three-wire pattern the secondary switch at the top is divided into two parts, but otherwise the arrangement is similar to the ordinary two-wire type.

There are several points in design of the apparatus to which attention should be directed. The form of the heavy current secondary switch at the top is particularly well adapted to its purpose; the fixed contact piece to which the cables are attached are of solid metal, and the moving bridge is laminated and of a form which makes a good wedge-like contact. It must be realised that this switch, although of large carrying capacity, is never called upon to break the circuit, so that not only is there no liability to arcing or burning of the surfaces, but only a very small travel is required. The arrangement of levers, &c., by which the switch only moves through a small fraction of the travel of the plunger, and a correspondingly large force is obtained on the contacts, is clearly shown in Fig. 2, and is most ingenious. By means of the action of the levers, the switch, when on or off, is firmly locked, so that not only is it unnecessary, as already stated, to keep the current on the coils continuously, but it is impossible for vibration to loosen the switch. The pull is obtained from a pair of iron-clad magnets of the "pot" type, back to back, with separate coils, and attracting armatures at either end. In the older designs the magnet cores were solid, but a magnet with radial laminations, somewhat similar to those of the core of the Berry type of transformer, is being introduced. The construction of the high-tension switch and of the switch which breaks the control circuit is simple, as can be seen from the illustrations.

The relay arm is provided with carbon contacts and an adjustable balance weight. A dash-pot is fitted, so that its action in causing the opening of the switch is not too rapid. This prevents oscillation of the load in the neighbourhood of the critical value, causing continual opening and closing of the switch. The terminals of the relay coil are entirely enclosed in porcelain covers. Above the relay are the fuses in the primary circuit of the small transformer. A very neat device is adopted to ensure the immediate transference of the load to the large transformer in event of a breakdown of the small transformer. These fuses, which are of a special type, are so arranged that should either of them blow, or even become overheated, a thin, varnished silk cord, hanging so that it just touches the fuse strips, will burn through and cause a weight to drop on the lever arm of the relay, so that the small transformer is immediately switched out. Very little attention is required in actual working beyond occasionally renewing the oil

Front view with case over high-tension switch removed.

FIG. 2.—DETAILS OF TWO-WIRE CONTROL PANEL FOR BERRY SERIES SYSTEM.

in the dash-pot and inspection of the carbon contacts, which should be trued from time to time by drawing a piece of fine emery cloth between them.

One object of the system is the reduction of the "all day" losses; the exact amount of saving in this respect, of course, depends on the "peakiness" of the

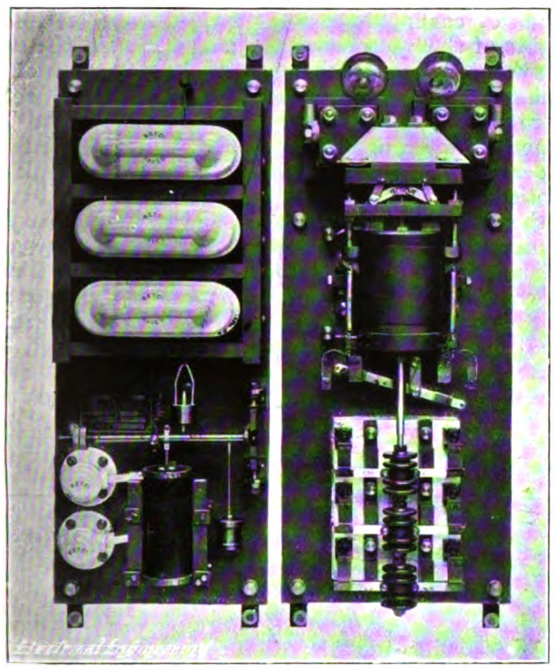

Fig. 3.—Three-phase Control Gear.

load, but under such conditions as an ordinary lighting load the reduction of losses claimed is such as to increase the all day efficiency of distribution from 70 to 90 per cent. The main transformer can be designed with lower copper losses, as it is not so necessary to cut down the iron losses. The result is that not only

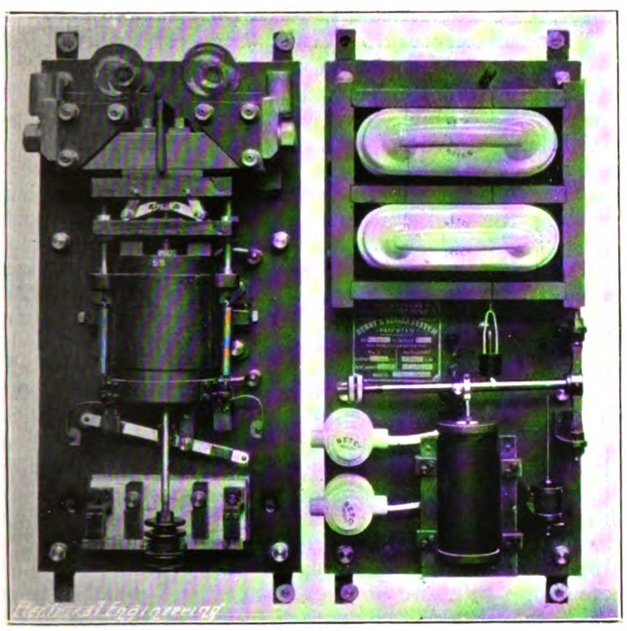

Fig. 4.—Single-phase Three-wire Control Gear.

at light load are the iron losses enormously reduced, but at heavy loads the copper losses, which in any case then predominate, are less serious; so that in both ways better overall efficiency is produced. It is also interesting to inquire into the effect upon the voltage regulation of the introduction of the system. At light loads the drop will be greater than before, as only the small transformer is in use, but when the large transformer is switched in, less drop than before will be obtained on account of the lower copper losses of the type of large transformer employed, and of the fact that, generally speaking, it will be cooler.

The effect upon the sub-station temperature is very marked. For example, in a sub-station in Hammersmith the temperature on one occasion was reduced to 68° F., when under similar circumstances before the series gear was introduced it had been 96° F. With regard to the conditions under which the transformers work, the fact that they are allowed to cool every day, and are cool when called upon to take up the load, is very greatly in their favour; and the intermittent nature of the heating of the core enables a smaller size of transformer to be used than would be the case with the ordinary arrangement. Another point which should be noticed is the fact that the cutting in and out of the transformers cannot occasion the deleterious voltage surgings and shock which are often produced by putting a transformer suddenly on to a circuit, as when the voltage is applied to the primary of the large transformer the core is already magnetically "in step."

The first equipment was installed about three years ago in a sub-station in Ealing, which formerly con-

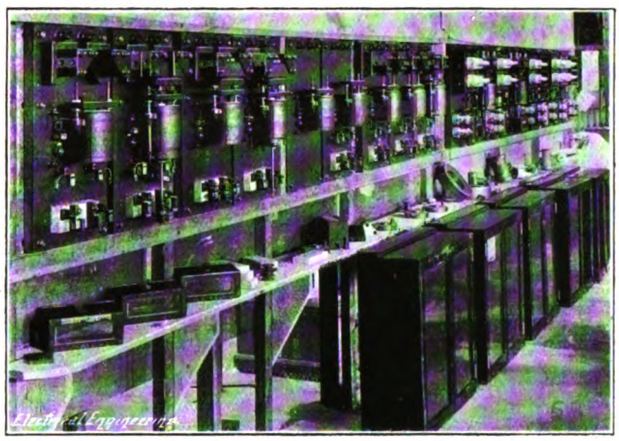

Fig. 5.—Group of Control Boards in Course of Erection.

tained a single 100 kw. transformer which had an all-day magnetising current of 0·7 amperes of 2,000 volts. This has been replaced by a transformer rated at 50 kw., which, owing to the intermittent nature of the work, is quite sufficient for the load under the new conditions, and a 10 kw. transformer for the day load with a magnetising current of less than 0·1 amperes. Similar outfits are in use at Hammersmith, Croydon, Reading, Scarborough, Wakefield, Bradford, Newcastle, and several other places both in this country and abroad.

The apparatus is made entirely at the works of the British Electric Transformer Co., at Hayes, Middlesex, which is the place of manufacture of the well-known Berry transformers. The control-boards are assembled together in batches. A group in a more or less finished stage is shown in Fig. 5 in course of erection. At the time of our visit to the works a large batch of completed boards were ready for dispatch to Shanghai. A rather ingenious arrangement is used for testing the relays and switches. A small bucket is attached to the relay lever, and gradually filled with water. The increased weight causes the lever to drop, but the bucket when full tilts up and empties itself, enabling the lever to rise again. The switch is, therefore, made to open and close periodically, and this is continued until the apparatus has been subjected to the equivalent of one or two months' regular work.

Looking round the works, we saw a large number of

Digitized by Google

transformers in progress of the oil-cooled and air-cooled Berry types of all sizes. Another speciality is an alternating-current booster, consisting of a small transformer with a number of tappings connected to a multiple-contact regulating switch, with two arms connected together by a choking coil to prevent interrupting the circuit or short-circuiting a section when passing from one step to another.

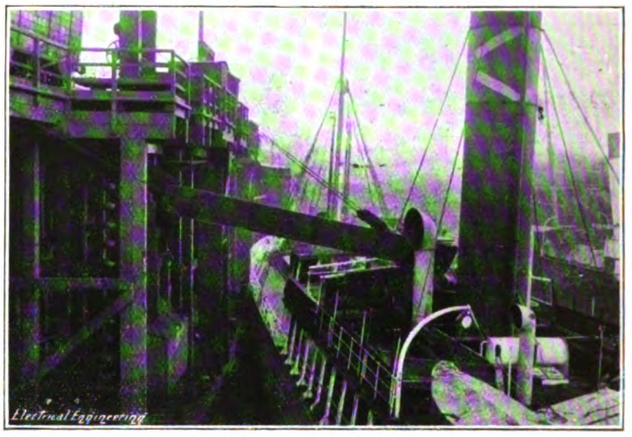
In conclusion, we wish to express our thanks to Mr. A. F. Berry for having afforded us facilities for examining the details of his interesting system.

ARC LAMP LOWERING GEAR

ON one or two occasions we have referred to forms of arc-lamp lowering gear made for special purposes by the London Electric Firm, of Croydon. A recent addition to their series is shown in the accompanying illustration, which represents three arc lamps mounted on special brackets at the Hammersmith station of the Metropolitan District Railway.

The gear consists of one of the firm's contact devices arranged

SPECIAL ARC LAMP SUSPENSION AT HAMMERSMITH STATION.



with the fixed part secured to the bracket, and the movable part to the upper end of the tube carrying the lamp. A flexible wire rope draws up this tube, telescoping it through the fixed part of the contact, and when the lamp is sufficiently high, it is swung round over the roof for trimming. The contact device is an adaptation of the firm's patent "one working part" type; and when the lamp is in its normal position the weight is entirely off the rope. The winch used is of the self-sustaining type without ratchets or gear wheels, so that the danger of running back is avoided.

Institution of Electrical Engineers, Dublin Section.—It has been arranged to hold the annual dinner, which was postponed from December 19th, owing to the death of Lord Kelvin, on Saturday evening, February 29th, at the Gresham Hotel, at 7 p.m. The charge for each member will be 5s., exclusive of wine. Members can invite any number of guests they may desire at the same rate per head.

ELECTRICITY IN COALING OPERATIONS

THE Tyne is one of the principal coaling centres of the world, and the magnitude of the operations carried out there render an indication of the means and methods whereby electricity is applied to the coaling of ships especially interesting.

It is a comparatively easy thing to arrange suitable means of coaling a vessel, provided that the relative heights of the vessel and the wharf remain the same, but this condition does not obtain in most of the coaling stations of the world, owing to tidal action. There are therefore found on the banks of the Tyne immense staiths or coaling jetties, whereby the trucks of coal can be taken right out from the bank and emptied into hoppers which discharge into the bunkers of the vessel. Where, however, it is necessary for engineering reasons to coal from the low quay edge, difficulty often arises from the fact that the level of the vessel's deck is higher than that of the quay, and in order to overcome this the North-Eastern Railway Company have included in their installation at Tyne Dock, electrically-driven coaling spouts, which render operations independent of gravity. These spouts for the shipment of coal at the staiths are of an effective length out from the quay edge of from 19 to 28 feet,

ELECTRICALLY-WORKED COALING SPOUT ON THE TYNE.

the distance varying according to the angle from the horizontal to which they are set. In these spouts, which have a width of 4 ft., travelling bands run, which carry the coal into vessels whose decks are at such a height from the water that in ordinary gravitation working the coal would not flow down the usual spout. As a matter of fact, these electrically-driven spouts will admit of coal being carried upwards to the bunkers of the vessel up to an angle of 18° above the horizontal line of the spout, thus giving a considerably greater range to the class and size of the vessel which can be coaled from the quayside.

The working capacity of the spouts is from 500 to 600 tons per hour, and the illustration gives a general idea of their appearance in operation. The drive is from electric motors of the three-phase type, thoroughly enclosed in order to protect the gear from flying coal dust, and the supply is taken from the mains of the County of Durham Electric Power Supply Co. The electrically-driven coaling spouts, which have been for some time in continuous operation, and which during the recent sustained pressure of foreign orders have been subjected to considerable pressure of work, have shown themselves capable of dealing with the demands placed upon them in a satisfactory manner.

The Royal Society of Arts.—His Majesty the King, who is patron of the Society of Arts, has granted permission to the society to prefix to its title the term "Royal," and the society will consequently in future be known as the "Royal Society of Arts."

PROTECTIVE DEVICES FOR HIGH-TENSION CIRCUITS

THE Paper by Mr. J. S. Peck on the above subject, which is to be discussed to-night at the London meeting of the Institution of Electrical Engineers, was read before the Manchester Local Section of the Institution on Tuesday last. The author in the introductory portion of the Paper pointed out that the question of protective apparatus for high-voltage transmission systems had not up to now received much attention in this country owing to the scarcity of high-tension overhead lines and the rarer occurrence of severe thunderstorms as compared with the Continent and America. Static disturbances were, however, sometimes due to other causes than lightning, and underground cable systems of large capacity were particularly liable to such disturbances.

In dealing with the "static" disturbances produced by switching, short-circuiting, grounding, and lightning, or in any other way which produces a very abrupt change in potential, he referred to their distinguishing features of oscillatory nature and extreme suddenness of action. One of the best-known effects due to static is the concentration of potential upon the outer turns of the windings of electrical apparatus. For example, each turn of the high-tension winding of a transformer has a static capacity to the low-tension winding and to ground. Each turn also has a certain amount of inductance. Consider the case of switching such a transformer into circuit; before the switch is closed both windings are at zero potential. When it is nearly closed a spark passes from the line at the instant of maximum line voltage. This outermost turn is immediately brought up to line potential; the next turns in order follow it rapidly, but no turn can reach full potential until the capacity connected to it is fully charged.

This effect is produced by any action which causes a very abrupt change in potential of the end turns of a transformer, and may occur in a high-voltage motor or generator in exactly the same way. It has no tendency to cause a breakdown to earth, but tends to produce short-circuits between adjacent turns. It is one of the most frequent sources of trouble in high-voltage apparatus.

The phenomenon of reflected waves of potential was explained as follows:—If a condenser is fully charged and then

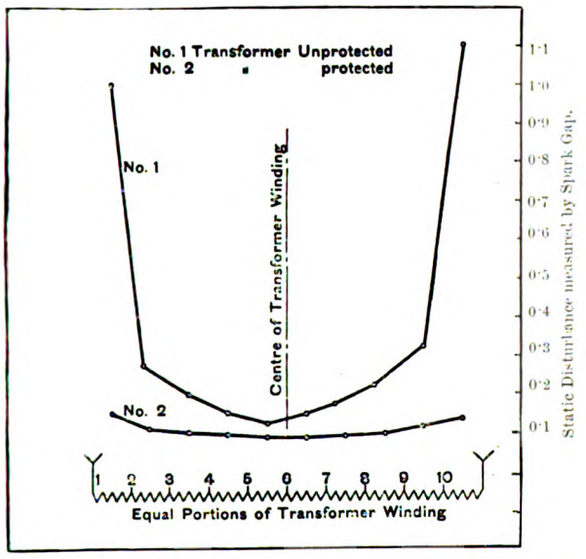

FIG. 1.—CURVE SHOWING PROTECTION AFFORDED BY CHOKE COILS.

discharged through a reactance, the current will increase until the condenser is entirely discharged, when the whole of the energy will be stored in the reactance; but the energy cannot remain thus stored, and the reactance begins to discharge into the condenser, which is charged to its original potential, but in the opposite direction. The condenser cannot remain charged, but again discharges into the reactance, so that the charge oscillates between reactance and condenser until it is used up in ohmic loss and leakage. If a condenser is without charge, and we charge it from a constant potential line through a reactance, current flows into the condenser through the reactance at an increasing rate, which reaches a maximum when the condenser reaches line pressure. The current through the reactance cannot stop, however, but continues to flow into the condenser until it is charged to double-line pressure. The condenser, however, cannot remain at double potential, but discharges through the reactance into the line, and continues to oscillate between zero and double-line pressure until it finally comes to rest at line pressure. Thus it is possible to obtain double the original pressure on a condenser when charging it through reactance. A transmission line is made up of condensers and reactances in series. If an unloaded line is connected at one end to a constant potential source, a charge passes into the line and advances at a certain rate depending upon the constants of the line. When it reaches the open end of the line it can go no further, but on account of the inductance of the circuit the charge is increased until approximately double potential is reached at the end of the line, but the end of the line cannot remain at double potential, and the charge is reflected back along the line, bringing it to double potential. The next wave reduces it to line potential, and the reflected wave to zero potential. Thus the line oscillates from zero to double-line potential until it finally comes to rest at line potential.

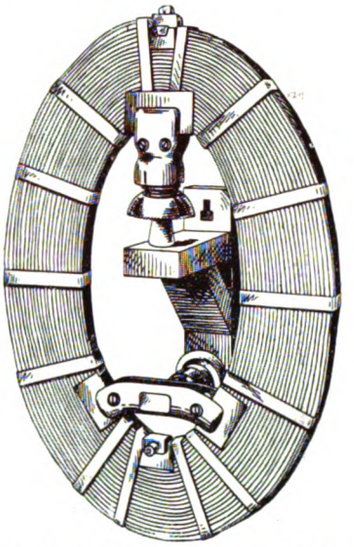

FIG. 2.—CHOKE COIL FOR ALTERNATING-CURRENT CIRCUITS.

It is not necessary that the line should be open-circuited in order to obtain a reflected wave and a potential rise, for if there is a branch line at the end of the main line, and the branch has less capacity than the main line, it will be unable to absorb the charge as rapidly as it arrives at the junction, and a rise in potential will occur. Every line has a natural period of oscillation, and if the frequency of the generator is such as to increase the magnitude of the oscillation, resonance occurs, and there is practically no limit to the voltage which may result. Fortunately, the frequency of oscillation of a transmission line is so high that there is very little chance of resonance with the generator frequency. On very long lines there is, however, the possibility that there may be resonance with some of the higher harmonics, and for this reason it is desirable that the generator should deliver an E.M.F. wave which has as nearly as possible a sine-form.

The static disturbances described above may be said to be caused by internal workings, but the most severe strains to which apparatus is subjected are due to lightning. It is evident from what has been said that, regardless of the source of the static disturbance, there are at least two dangers to electrical apparatus on transmission systems:—(1) Concentration of potential on the end windings, causing shorts between adjacent turns; and (2) excessive voltage between wires and ground, causing breakdowns to ground over insulators, bushings, or through the insulation of the windings.

In order to prevent trouble from the first cause, two courses are open—(*a*) To insulate the end windings so that they will withstand the strains. This method is often used, but it is always expensive, and on certain types of apparatus very difficult to apply. (*b*) To prevent the windings being subjected to the abrupt change of potential. In the case of switching, danger may be prevented by closing the circuit through a resistance or adopting certain other means, but the most effective

Digitized by Google

remedy, and one which is good for practically all cases, is to place choke coils between the apparatus and the lines from which the static disturbance comes. With this arrangement the shock is taken by the choke coils, which can be heavily insulated to withstand it, and if the coils should break down they are readily repaired or replaced. The use of a choke coil may be said to be the same (so far as the static strains are concerned) as placing the end turns outside the apparatus, where there is plenty of room for insulation. The effect of a choke coil in reducing strains on the end windings of a transformer is shown in Fig. 1, where the voltages across different numbers of turns near the line are measured with and without a choke coil. A type of choke coil for this purpose is shown in Fig. 2.

In order to prevent trouble from the second cause, that is, high voltage to earth, the lightning arrester is used to afford a path to earth for static discharges of lower resistance than that offered by the insulation of the transmission line or of the apparatus connected to it. The requirements for a good arrester are conflicting. It must offer an easy path to earth, yet must be able to hold back the line voltage, and when a discharge occurs it must be able to interrupt or suppress the arc which follows the discharge. All arresters, except the water-jet type, consist of at least one air-gap in series with an

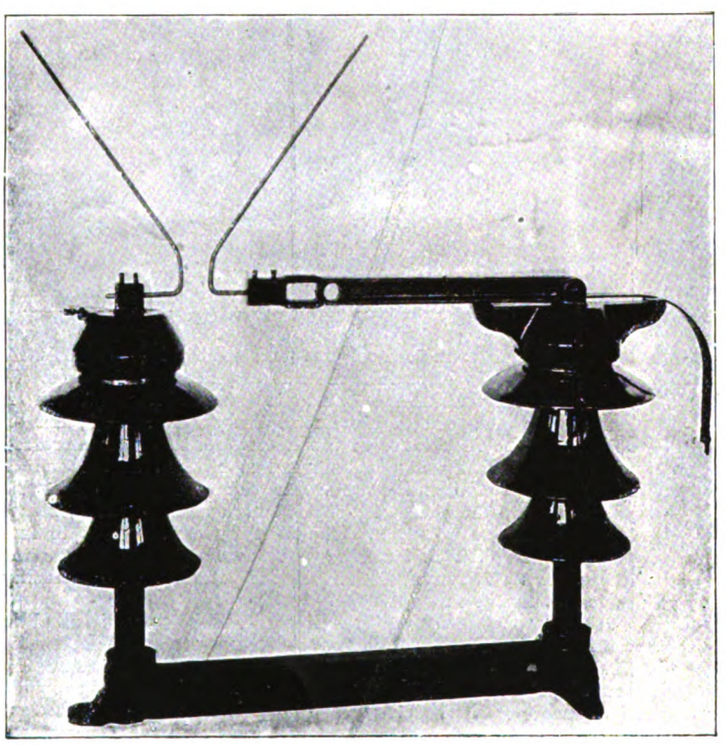

FIG. 3.—HORN TYPE LIGHTNING ARRESTER.

arc-suppressing device. In the case of alternate-current arresters there are often a very large number of gaps in series.

Horn-type Arrester.—This consists of two wires, or rods, each bent at an acute angle, the two being placed in such a position that the air-gap is small at the bottom, but increases rapidly from bottom to top. One horn of the arrester is connected to line and the other to ground, and the arrester so adjusted that the gap at the bottom is just large enough to withstand normal or slight increases above normal voltage. When there is an excess voltage an arc passes across the small part of the gap, and due to its heat rises until it is drawn out so long that it is ruptured. The advantage of this type of arrester is that it is cheap and can be installed out of doors. The objections are that the arc takes a long time to break, and, since it constitutes a short-circuit on the system, will throw synchronous apparatus out of step. It is now customary to instal a high resistance in series with this arrester in order to limit the current which flows on short-circuit, but this resistance retards the static discharge. This arrester requires a much higher resistance in series with it than certain other types. This form of arrester is shown in Fig. 3.

Non-arcing Multi-gap Arresters.—It was discovered by Wurts that certain metals had the property of suppressing alternating arcs. The non-arcing multi-gap arrester consists of a number of small metal cylinders separated by air-gaps of approximately $\frac{1}{32}$ in. (Fig. 4). The number of gaps between line and ground is made great enough to suppress any arcing which occurs after a static discharge. This arrester proved a great success on

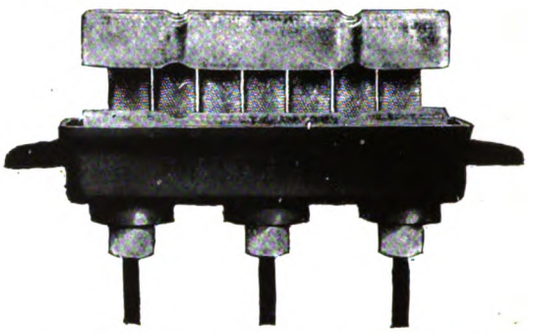

FIG. 4.—NON-ARCING METAL ARRESTER UNIT.

circuits of 2,000 volts, and was used to some extent on voltages as high as 15,000 and 20,000. It was found, however, that on large generating systems, and particularly with high voltages, the arresters did not always retain their non-arcing quality, or else that an enormous number of gaps were required. Thomas discovered that in order that an arrester should be non-arcing it was necessary to limit the amount of current which flowed after the arrester discharged. This at once suggested an ohmic resistance in series with the gaps, but on high potential circuits the insertion of sufficient resistance to render the arrester non-arcing increased greatly the resistance which the arrester offered to static discharges. He found, however, that the resistance of the arrester to static discharges could be greatly reduced by using a large number of gaps and comparatively small series resistance, and shunting part of the gaps with an ohmic resistance. This he called a low equivalent arrester; the general arrangement is shown in Fig. 5. The action of the arrester is as follows:—Approximately twice as many gap units are taken as are required to hold back the line voltage. Approximately one-half of the gaps are shunted with an ohmic resistance. When no discharge occurs the ground potential is brought up to the middle of the series. Thus there are between line and ground only one-half the total number of gaps. When there is an excessive potential on the line, the non-shunted gaps break down first, so that full potential is thrown across the shunted gaps, and they also break down. The arc through the shunted gaps is, however, very unstable and quickly drops out, the current passing through the shunt resistance, but the non-shunted gaps now have in series with them the shunt resistance and the series resistance, so that the current passing through them is very small and the arc is quickly suppressed. Although the two series of gaps do not break down simultaneously, the whole action is, of course, very sudden and appears instantaneous. This arrester has been very successful, and the principle with various modifications is now used on practically all arresters of the multi-gap type.

One objection to the multi-gap arrester is that on high voltages an increase in the number of gaps out of all proportion to the increase in voltage is required in order to hold back the line voltage and to make the arrester non-arcing. It was

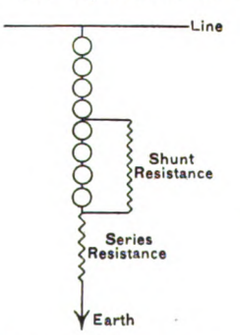

FIG. 5.—ARRANGEMENT OF "LOW EQUIVALENT" ARRESTER.

FIG. 6.—ARRESTER UNITS WITH EARTH SHIELD.

Digitized by Google

found also that the number of gaps varied greatly on different circuits, and this difference was finally traced to the position of the arrester with reference to grounded objects. The explanation of the phenomena is believed to be as follows :—

When ground potential is brought near the arrester, the potential gradient across the gaps near the line becomes so high

Fig. 7.—Water Column Lightning Arrester.

that the air between the cylinders becomes ionised, and the line potential is gradually moved towards the grounded end of the arrester until there are not sufficient gaps to hold back the line voltage and a discharge occurs. When the arrester is well removed from grounded objects, *i.e.*, from the walls of buildings, &c., the total potential strain from line to ground is divided more equally between the cylinders, consequently the arrester will stand a higher potential, or a smaller number of gaps are required for holding back the same potential.

With high-potential arresters a hissing sound is often noticeable. This is caused by static sparks which pass continuously from the line wire to the cylinders which are adjacent to them. The closer the arrester is to grounded objects, the further will this display extend downward toward the ground from the line terminal. To overcome this unequal distribution of potential across the gaps, a metallic ground shield connected to the line is placed adjacent to a portion of the gaps furthest from the ground, thus the line potential is brought near to these gaps, and the excessive potential gradient removed. This arrangement is shown diagrammatically in Fig. 6. It is found in practice that the use of the shield often permits a great reduction in the number of gaps to be made.

Mutiplex Arrester.—While the lightning arrester is intended primarily to afford an easy path to earth for static discharges, it has been found that a high static potential sometimes exists between the different wires of a transmission circuit. To take care of this, the General Electric Company of America brought out the multiplex arrester. In this arrester, which is of the multi-gap type, an ohmic resistance is connected from about the middle point of the series of gaps in one phase to the corresponding point of the arrester in the next phase. Thus all the arresters are connected together by a high ohmic resistance at approximately their middle points. and it is possible for a static discharge to pass half-way through one arrester, through the ohmic resistance, and through half the number of gaps in the other arrester to the opposite side of the circuit.

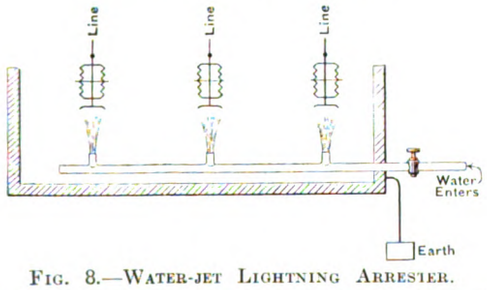

Fig. 8.—Water-jet Lightning Arrester.
The Water sprays upwards and strikes against the Plates which are connected to the Line Wires.

Water-jet Arresters.—On the Continent an arrester, consisting of jets of water playing upon the wires, has been used to some extent. The chief objection to this type is that it causes a leakage of current to earth which represents a loss of power, and if the resistance is sufficiently high to prevent serious loss due to leakage, it may offer considerable resistance to static discharges. It is, however, comparatively cheap, and appears to have given satisfactory protection, and there is no reason why an air-gap should not be placed between the line and the jet, though this would increase the resistance to the discharge. Its use is limited to places where there is a supply of water, unless pumping is resorted to. There are a number of different forms of this arrester, two are shown in Figs. 7 and 8.

Arresters in Parallel.—Much discussion has taken place regarding the effect of series resistances in lightning arresters in retarding static discharges. The static charge is represented by a certain current at a certain voltage. If the resistance of the arrester is low enough, so that the voltage of the charge can force the current through the arrester resistance as fast as it arrives at the arrester, then there will be no further rise in potential, but if the resistance cannot pass the current at this rate, there will be reflection and a rise in potential. To overcome this difficulty a number of arresters may be installed in parallel, the arresters having different gaps and different resistances. The arrester with a minimum gap has the maximum resistance, and the arrester with a maximum gap has the minimum resistance. The theory of the operation is as follows :—

When a discharge occurs it will jump the smallest gap, and if the current is not too large for the resistance there will be no rise in potential, but if the current is too large there will be a rise in potential, and the next larger gap will break down. With a very high rise the largest gap with minimum series resistance will break down. On some transmission systems arresters have been installed which consist simply of a horn-gap in series with a fuse. The gap is set so high that it will be broken down only with a very high rise in potential. This arrester, which offers a direct path to earth, is probably as good a means as any yet devised for taking care of a direct lightning stroke. Several of these arresters are connected in parallel, and usually only one discharges at a time, so that the line is not left unprotected, and arrangements are made for replacing fuses quickly.

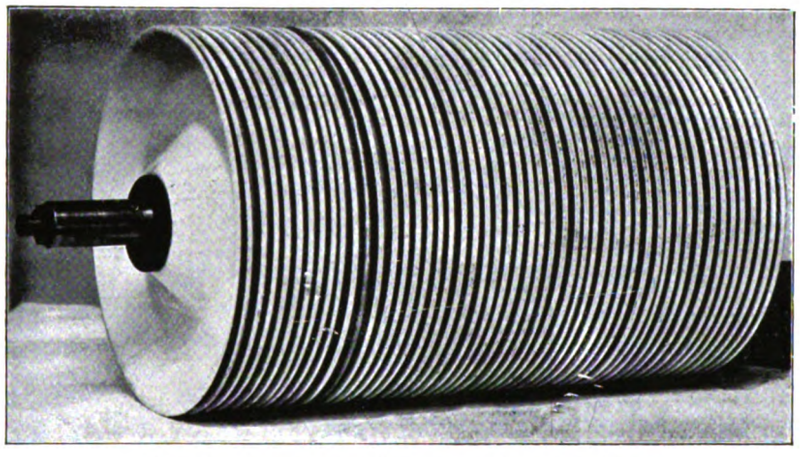

Fig. 9.—Electrolytic Lightning Arrester Unit.

The Electrolytic Arrester.—It has been found that aluminium in certain electrolytes forms a non-conductive film on its surface. This film, although extremely thin, will withstand about 400 volts. At higher voltage the film is punctured with countless small holes, and a large current is permitted to pass, but when the voltage drops below the critical value the film is reformed and prevents further passage of current. A sufficient number of these cells may be placed in series to withstand almost any voltage desired. It is evident that the aluminium cell possesses almost ideal characteristics for a lightning arrester, as it permits very little current to pass at normal voltage, but breaks down at higher voltage and re-seals itself as soon as the high voltage has passed and the line has been relieved. When voltage is applied to the aluminium cell, a small current, partly capacity and partly leakage current, flows through it, and for a lightning arrester it is desirable to use a gap in series with the cell in order to prevent this current flow.

In order to obtain a large number of cells in series, the aluminium plates are pressed into tray form. These trays are set one inside the other (Fig. 9), and separated by suitable insulating washers. They may thus be built up into a column comprising a large number of cells in series. The columns are

Digitized by Google

enclosed in suitable earthenware jars, and the trays filled with the electrolyte. This is done by filling the top tray and letting the electrolyte run over into those below. After the trays have been filled, the jar is tipped slightly, so that a small amount of the electrolyte runs out of each tray, and a small amount of transformer oil is then poured into the top tray, and permitted to run over into those below. This oil prevents evaporation of the electrolyte. A number of jars may be mounted

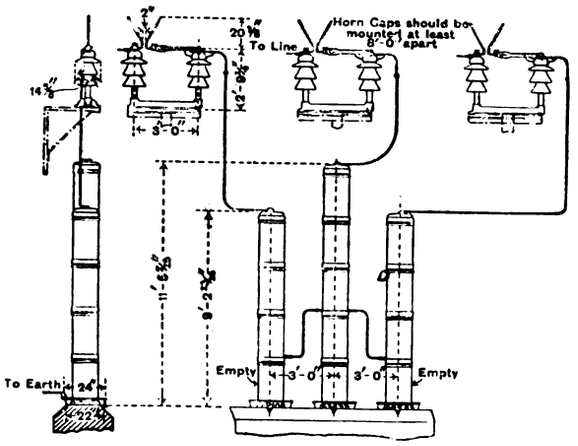

FIG. 10.—OUTLINE OF ELECTROLYTIC LIGHTNING ARRESTER FOR 53,000 TO 66,000-VOLT THREE-PHASE CIRCUITS WITH UNDERGROUND NEUTRAL.

one above the other for high voltages, and as the edges of the trays do not touch the jars, current must pass from tray to tray.

For voltages not exceeding 13,500, a gap consisting of the usual non-arcing metal cylinders is placed between the line and the electrolytic unit. For higher voltages the horn-type gap is used. The gap used must have sufficient power to suppress the arc which exists after the static disturbance has passed. The cur-

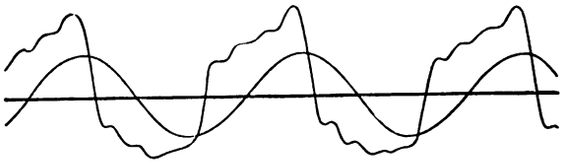

FIG. 11.—OSCILLOGRAPH SHOWING CURRENT AND VOLTAGE ON ELECTROLYTIC UNIT, 12,500 VOLTS, 25 CYCLES, 0·41 AMPERE.

rent in this arc is quite small. It is not advisable to use a horn-type gap on the lower voltages, as it must be set so close that the arc does not rise properly and extinguish itself.

A diagram of the arrangement of this arrester is shown in Fig. 10, and oscillograph curves showing current and voltages on an electrolytic unit are shown in Fig. 11.

Ground Wire.—The concensus of opinion seems to be that one of the best methods of protecting a transmission line from

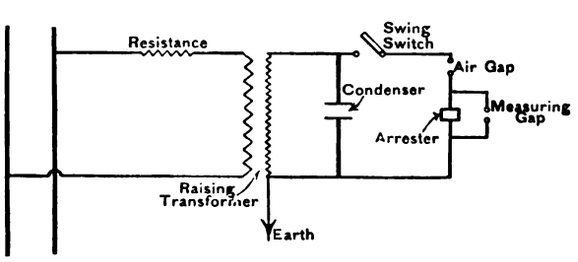

FIG. 12.—DIAGRAM OF CONNECTIONS FOR METHOD OF TESTING LIGHTNING ARRESTERS.

lightning is to string a wire above the transmission line, this wire being grounded at frequent intervals. Three wires, one above and one at each side of the transmission circuit, are recommended as affording very complete protection. It is the general practice, however, to instal lightning arresters at the ends of the line, whether ground wires are used or not.

Testing Lightning Arresters.—Before concluding this Paper, a few words were said regarding the methods of testing the protective power of lightning arresters. Fig. 12 shows one system of connections which is used. A condenser is charged to a high potential from a raising transformer. This condenser is discharged by means of a swing switch through a spark-gap in series with the arrester. In shunt to the arrester is an adjustable spark-gap, which affords an alternative path for the discharge. The gap is adjusted until the great majority of the discharges, say 95 per cent., pass through the arrester instead of over the gap. The length of the gap under this condition is called the equivalent spark-gap of the arrester, and means an air-gap of such a length that a slightly higher pressure is required to break it down than is required to break down the arrester. Obviously, the lower the equivalent gap the greater is the protective power of the arrester, as the gap represents somewhat less than the minimum insulation strength which the arrester will protect. In order to test the non-arcing power of the arrester, the adjustable spark-gap may be replaced by connections to the power circuit. When a discharge passes through the arrester, the arc which follows from the power circuit should be quickly suppressed.

The International Telegraph Conference.—It is announced that China will be represented for the first time at the coming telegraph conference at Lisbon in the person of Mr. Dresing, foreign adviser to the Chinese telegraph service.

New Telephone Charges.—An action is down for hearing in the City of London Court on February 13th, which is taken by the Postmaster-General against the London Paper Supply Co., in connection with what is alleged to be persistent over-charging by the Post Office for telephone service upon the message rate system. The London Paper Supply Co. allege that they have been charged for calls not made to the extent of £1 16s. 6d., and they claimed the return of this amount from the Postmaster-General. In this they were unsuccessful, and after their telephone connection was cut off, they refused to return the instruments. It is to recover the instruments that the Postmaster-General is taking the action in question. The action will raise the whole question of the accuracy of the Post Office methods of registering calls under the new message rate system of charging.

Breach of Contract for Electricity Supply.—In the King's Bench Division of the High Court, on Wednesday and Thursday last week, Mr. Justice Ridley and a special jury heard the action of Bourne and Another *v.* The Marylebone Borough Council, in which the plaintiffs, who are drapers, of Oxford Street, claimed damages against the defendants for alleged breach of contract. It appears that a contract was made between the parties, under which the defendants agreed to supply electric light to plaintiffs' premises, newly opened in Berners Street, at 240 volts by the first week in September of 1905. It was alleged on the part of the plaintiffs, however, that the defendants failed to supply by that date, and no supply was given until October 9th, 1905. A temporary supply was agreed upon at 200 volts, but the plaintiffs did not get the light within the time specified in the new contract. It was pleaded on the part of the defendants that their representatives had no authority from the defendants to enter into any of the contracts, and that neither of the alleged contracts had the seal of the Corporation. Evidence having been heard, the jury found for the plaintiffs on all the points, but before judgment would be entered it was arranged that the case should stand over for legal argument as to the defendants' liability. On this point the case came before Mr. Justice Ridley on Friday, when his lordship reserved judgment.

Nuisance from Brighton Corporation Motor Generator Station.—This action, in which the Rev. Edward Heath, Colonel Grove-Morris, and Mr. Frank Harold claimed an injunction to restrain the Brighton Corporation from working their North-road Electric Works so as to cause a nuisance to the worshippers of St. Mary and St. Mary Magdalene Church, in Bread-street, Brighton, was continued before Mr. Justice Joyce in the Chancery Division of the High Courts on Thursday. The evidence was completed at the previous sitting, and was reported in our last issue. Mr. Astbury, K.C., addressing the Court, submitted on behalf of the Corporation that the evidence of the plaintiff clearly established that no possible legal nuisance existed. It was, he said, impossible to deal with the case seriously; so infinitesimal was the noise, no words of the English language could express the character of the sound. The Corporation had done everything possible to meet the plaintiffs, but as trustees of the ratepayers there must be a limit to their kindness and charity. If this case went against the Corporation there would be hundreds of blackmailing actions. If the plaintiffs agreed to the action being dismissed the Corporation would not press for costs, but beyond that the Corporation would not go. The hearing was continued on Friday, and after the Court had been addressed on behalf of the plaintiffs his Lordship reserved judgment, remarking that he might visit Brighton personally in order to satisfy himself respecting the alleged nuisance, or send an expert to report on the matter.

THE WEST HAMPSTEAD ACCIDENT

THE full report of Major J. W. Pringle of the Board of Trade inquiry into the accident which occurred between two electric trains at West Hampstead Station of the Metropolitan Railway, under circumstances already reported in ELECTRICAL ENGINEERING (Vol. II., pages 672, 685, 770, and 829, and January 16th, page 70), has now been issued. It will be remembered that the down train from Baker Street to Willesden Green was standing at the platform in the station waiting for the signal to proceed, and the following train was admitted into the station under all proper signals during the prevalence of a thick fog, and struck the rear of the standing train. Three passengers were killed. The constitution of the trains and the damage done are set forth in the report, and full details, with a plan of the scene of the collision, are given, together with a description of the working of the Spagnoletti electric lock and block system of signalling in use on the part of the line in question. Briefly, the electrical interlocking ensures that the passage of a train over a treadle in front of the home signal at West Hampstead releases the instrument, which allows the signalman at West Hampstead to free the lever working the down starting signal at Finchley Road. Again, the passage of a train over a treadle in front of the down starting signal at West Hampstead releases the disc instrument which permits the signalman at West Hampstead to free the lever working his own down home signal. It must be noted that this disc instrument is only released if the treadle in front of the down starting signal is operated whilst the starting signal lever is in the safety position. If the signal lever is at danger when the treadle contact is made the instrument will not be released. Lock indicators are provided in the signal-box behind each signal lever, which is electrically controlled. These visually indicate whether the lock is "on" or "off." In case of a failure of the electrical releasing arrangements, or when a train arrives at the station, but does not proceed further, it is necessary to provide means whereby the signalman can release his disc instruments and his lever locks. For this purpose there are fixed in the signal-box a number of small release boxes with glass fronts. These contain release springs, which, when operated by hand, release the disc instruments.

After detailing the evidence before the inquiry, the report proceeds to the conclusions and deals first with the accepted facts, about which there is no conflict of evidence, and finds that in the circumstances no blame or responsibility for the collision can be attributed to either motorman Smith, the guards of the Neasden train, or to fog-signalman Tomes.

In dealing with the discrepancies between the evidence of signalman Hollis, of West Hampstead, and others, Hollis's own account of his dealings with these two trains is summarised as follows:—His usual practice was to offer a down train to Kilburn, when it had arrived at West Hampstead. Contrary to this usual custom, he offered the Willesden Green train, had it accepted, and lowered his down starting signal very soon after he had accepted the train from Finchley Road, and some time therefore before the train arrived at West Hampstead. He estimates that the approximate time for this action was 7.45½ a.m. He then proceeded to enter in his train register book the timings of several up and down trains. Whilst so engaged he heard the noise of a train approaching, and judged it was the Willesden Green train. He therefore entered in the train book the arrival and departure of this train as 7.46 and 7.46½, and at the same time, in accordance with his general practice, he bocked the time of the receipt from Kilburn of the clearance signal for the train as 7.48. Shortly afterwards, turning towards the lever frame, he saw that the discs of his down "Kilburn" and down "additional" instruments were both showing "Line clear." This would indicate that the Willesden train had arrived at Kilburn, if all was correct. He had not then cleared back to Finchley Road for this Willesden train, and all his down line signals were standing at "Clear." He therefore replaced all his down line signals at danger, and cleared back to Finchley Road on the bell instrument. Therefore, when the Neasden train was offered him, he accepted it, released his down home signal lock in the usual manner, by working the tapper of his down additional disc instrument, and lowered the down home and distant signals, so that the train shortly afterwards entered the station, and the collision took place.

Signalman Boggis at Kilburn absolutely denies that he received any signal for the Willesden Green train at or about 7.45½. He did not, therefore, accept it, or release the starting signal at West Hampstead. He further asserts that no down line signal was sent to him from 7.43 until 7.52 a.m. If this be true Hollis could not have lowered his down starting signal between these named times.

This statement of signalman Boggis is corroborated by ganger Coleman, who was on the platform at West Hampstead when the collision occurred, and a few seconds later ran into the signal-box. He declares that he saw Hollis go to the Kilburn bell instrument and ring a train on, and afterwards pull off the down starting signal. He also heard an acknowledgment received on the bell instrument. If Coleman's evidence is believed, the time, 7.52, given by Boggis for the receipt of a bell signal from West Hampstead, is substantiated. Hollis denies having sent any signal at 7.52 a.m. Again, there is overwhelming testimony that the down starting signal was not lowered from the moment when the Willesden train arrived until after the collision.

The evidence being overwhelming on the point that the down starting signal was at "Danger" the whole time during which the Willesden Green train was standing in the station, it follows that if his statement is to be credited, Hollis must have replaced his down line signals at danger after the Willesden Green train had passed the down home signal—otherwise motorman Spittle would have found that signal at danger when he passed it—but before the train had arrived at the platform. It is difficult to understand, continues the report, how he could have been so foolish, unless he was inattentive to his duties, as to place his starting signal at danger at the moment when the train was passing his signal-box and entering the station. But if his statement is believed, that he offered the Willesden Green train to Kilburn, and lowered the starting signal before the collision took place, this is what must have happened. He declares that when he put his signals to danger both his discs showed "Line clear." As he had not cleared back for the Willesden Green train to Finchley Road, the disc of his down Finchley Road instrument must have been either swinging in the neutral position, or showing "Train on line." He evidently refers, therefore, to the discs of the down additional and down Kilburn instruments. Now, if these two discs showed "Line clear," and the Willesden Green train had been properly offered and accepted, as Hollis declares, there must have been a failure of the electrical locking with both these instruments, for the Willesden Green train was still standing in the station, and had not operated the two treadles which release these instruments. Taking first the down Kilburn instrument. Any failure of the locking with this instrument would have been duplicated in the corresponding instrument at Kilburn, and must have been noticed by signalman Boggis. No failure of any kind was noted either before or after the accident. Moreover, such a failure would set the disc swinging in the neutral position, and would not expose the "Line clear" disc. There is in addition the emphatic statement of signalman Boggis to the effect that no train was offered to him between 7.43 and 7.52, and that he was not called upon to release the lock on the down starting signal at West Hampstead until 7.52. Since there was no failure of the electrical locking of the down Kilburn instrument at West Hampstead, Hollis could not have offered the Willesden Green train to Kilburn, and could not, therefore, have lowered his down starting signal, either before or after the train arrived at the station. In these circumstances, whilst the Willesden Green train was waiting for the starting signal to be lowered, the proper and normal position of the disc of the down Kilburn instrument was "Line clear," as Hollis describes. But if "Line clear" was the position of this instrument when Hollis put back his starting signal to danger, we must believe signalman Boggis's statement as corroborated by ganger Coleman's evidence, that Hollis offered him a train at 7.52 a.m., and that this train was accepted, otherwise the disc of the down Kilburn instrument at West Hampstead would not, after the accident, have showed "Train on line," as described by signalman Shepherd, but "Line clear." Two further conclusions most naturally follow. First, that the bell signal sent at 7.52 a.m. was intended for the Neasden train, and consisted, therefore, of one bell only, as Boggis asserts. Secondly, that when the starting signal was lowered in accordance with the evidence of Spittle and Coleman, very shortly after the collision, it was intended by Hollis for the Neasden train.

The case of the down additional instrument has now to be considered. The disc of this instrument should have been showing "Train on line," and the instrument should have been locked until the Willesden Green train passed over the treadle, situated about 107 yards in advance of the down starting signal. Until this treadle had been actuated by the train, it ought not to have been possible, with proper working, for Hollis to release the lock, and pull over the lever of the down home signal, in order to admit the Neasden train into the station. Hollis asserts that something went wrong with the electrical arrangements, which resulted in the wrong disc being displayed, and further permitted him to release the lock on the down home signal in the proper manner by working the tapper of the instrument. On the battery circuit for the additional disc instrument there are two breaks—not one only—where contact has to be made before the circuit is complete, and the operating current can pass. Contact in one case is made by the depression of the rail, under the weight of the train, against the lever arm of the treadle. When this lever arm, which is enclosed in a metal case, is in proper adjustment, it requires a weight of from five to six tons upon the rail to make contact. The second contact is made in the signal-box by the lever which works the down starting signal being pulled over in the lever frame to its furthest extent.

It is acknowledged by various witnesses that instances have in past years occurred where, owing to some movement in the

Digitized by Google

permanent way, or to want of adjustment in the treadle lever, the lock of one of these "additional" instruments has been released, after the starting signal had been pulled over, but before the train had operated the treadle.

An examination of the condition of the apparatus after the accident lead to the conclusion expressed in the report as follows :—

"As regards the down additional instrument, therefore, I hold that a failure causing an improper release did not take place, as Hollis asserts, and that when the Neasden train was signalled to him, the 'Train on line' disc must have been showing, and the instrument must have been locked."

The question remains, continues the report, how was the additional instrument unlocked? The spring contacts and keys are enclosed in small glass-faced boxes. These boxes are kept locked. Only a stationmaster, or station foreman, is authorised to open any of these boxes with the key. Where a release is required for the purposes of ordinary working, *e.g.*, for cancelling a train, signalmen are authorised to break the glass face of the release box. They are ordered to report all such breakages, and the station foreman or stationmaster is alone authorised to replace the glass from a store in his possession. It is necessary to open the case of the release box by means of the key in order to replace the glass. The lock of these release boxes is of the lever pattern, and the key, which has five tumblers, is not of a complicated description. If Hollis owned a key of this pattern, he could have opened the box, pressed the spring, and thus made it possible for himself to release the lock on the down home signal. There is no evidence of any description to show that he had such a key in his possession at the time of the accident; and as no one was in the signal-box with him, it cannot be directly proved that he opened one of the release boxes on this occasion. But without breaking a glass, or opening a box with a key, I do not think, says Major Pringle, it would have been possible to obtain a release of the down home signal lever.

Some points connected with the neglect of certain rules, &c., which have a bearing on this accident are then dealt with, and the conclusions are given as follows :—

1. That the first (Willesden Green) train was not, on arrival at West Hampstead, put into block to Kilburn, and that the starting signal was consequently not lowered. The result was that the train was kept standing at the platform for five or six minutes before the collision happened.

2. That, in all probability, owing to the thick fog, the train, as it stood at the platform, was out of sight of the signalman; but nothing was done in accordance with the company's rules to remind him of the position of the train.

3. That the electrical and mechanical signalling arrangements were in working order, and that it was not possible, with proper usage, and in accordance with the regulations, to lower the down home and distant signals for the second (Neasden) train to enter the station, until the first train had left the station.

I find, therefore, that the collision was caused by forgetfulness in the first instance, and subsequently by some illegal manipulation of the electrical instruments or locking on the part of signalman Hollis. He must bear the full responsibility for his conduct. Further, I find that the collision might, in all probability, have been prevented, if motorman Spittle and guard Sills had carried out general rule No. 55 (*a*), which is applicable on the company's system to trains standing within station limits. To some extent responsibility falls upon these men for not carrying out this rule. Station foreman Fitch failed to act in accordance with Rule 61 (A) and appoint a ground fog-signalman, or detail one of the station staff, to assist Hollis. It is evident he has not properly supervised the manner in which the signalmen perform their duties, or observed the company's rules regarding the use of the release key-boxes. Signalman Boggis was wrong in accepting a train when he thought it had been improperly signalled. But having regard to the time the signal was received, *i.e.*, after the collision, as the evidence shows, this error was not a contributory cause of the accident.

The report concludes with the following remarks :—

It is generally recognised that an automatic system of signalling is best adapted for a railway where block sections are very short and traffic of high frequency. The company's system of "lock and block" signalling has done excellent service in the past. This is proved by the fact that, from the opening of the railway in 1863 until the date of this unfortunate collision, some three thousand millions of passengers have been carried without the loss of one life in a train accident. The maximum number of trains dealt with during the winter at West Hampstead, in one signalman's tour of duty—eight hours—is 226, an average of 28·25 per hour. During the summer months the average is sometimes as high as 36 per hour. Having regard to the number of movements involved in passing so large a traffic on the "lock and block" system, a machine-like regularity of action is necessary, which can best be supplied by an automatic method of working. The company have for some time past been experimenting with a system of train-controlled signalling, with a view to adopting it on their lines. But every detail must be thoroughly proved by long and continuous tests under working conditions before the method can be accepted. Some time, therefore, must elapse before any complete change in the signalling arrangements can be carried out.

CORRESPONDENCE

TELEPHONE PROGRESS ON THE CONTINENT.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—There has recently been much discussion of what is known as the measured rate tariff for telephone service, and a few months ago a statement went the round of the Press to the effect that in Germany, Belgium, and France telephone rates for unlimited service were materially lower than those in force in this country. Also, there have been efforts to discredit the technical policy of the National Telephone Company and the Post Office in the important matter of the adoption of the central battery system of working large telephone exchanges.

I have just returned from a tour on the Continent devoted exclusively—barring one week in the Engadine devoted exclusively to more alluring affairs—to the study of telephone conditions. I visited Antwerp, Brussels, Rotterdam, The Hague, Amsterdam, Hamburg, Berlin, Vienna, Munich, and Paris, and in each place conferred with the principal telephone authorities, visited the chief exchanges, and was made fully acquainted with recent progress and future plans, both technical and administrative. Well, everywhere I find that measured rates and central battery equipment are the order of the day. I talked with perhaps fifty telephone officials, administrators, engineers, and executives, ranging from an Under-Secretary of State down to an exchange manager, and, among them all, Belgian, Dutch, German, Austrian, and French, there was no difference of opinion as to the correctness of the measured rate tariff for telephone service, and as to the efficiency of the central battery system of working large telephone exchanges.

Practice is following precept with more or less rapidity. Germany, which contains about half the total telephones in use on the Continent, is about to abolish the unlimited rate entirely, and in a short time all telephone subscribers in the German Empire will pay for their service at measured rates. An interesting detail is that in the new German tariff the lowest rate at which calls will be sold to the large user is exactly the same as the corresponding figure in the National Telephone Company's tariff, viz., 0·48d. per call. Austria abolished unlimited rates last year, and all Austrian telephone subscribers now pay measured rates. There was much opposition to the new tariff, especially from the large users in Vienna, but common sense has prevailed, and the Austrian Administration is now enjoying a rapid increase of subscribers, particularly among private houses and small users generally, owing to the much more elastic tariff which the measured rate scheme provides.

In Belgium a measured rate tariff is under discussion, and the responsible Minister has announced that a new scale of telephone rates will shortly be introduced. In France the leading officials of the Telegraph Department have long been convinced of the correctness of the measured rate principle, and a committee is about to be appointed to prepare a new tariff.

Therefore, whereas it has recently been represented in the British Press that telephone service is supplied in the principal Continental countries at absurdly low figures for unlimited service, the facts are that measured rates are either actually in force or about to be adopted. And when a change of this sort is made by a Government Administration on the Continent it is not done in the gradual and genial way adopted here by the National Telephone Company and the Post Office, who allow old subscribers to retain their existing arrangements until convinced of the superiority of newer methods. The Continental subscriber finds his contract changed for him, whether he likes it or not.

As with measured rates, so with the central battery system. This would hardly be worth mention were it not for the efforts of those connected with the defunct municipal telephone movement to discredit modern telephone work, for among serious telephone engineers there is no difference of opinion as to the superior efficiency of central battery working. Everywhere on the Continent new central battery exchanges are coming into use, and old local battery systems are being abandoned and replaced by central battery plants. The reconstruction of the Berlin system with central battery plant for 100,000 lines is nearly complete, similar work at Hamburg is in course of execution, while many of the smaller systems in Germany have already been converted. In Belgium, Holland, and Austria new exchanges are all central battery, and old ones are gradually being rebuilt on the same lines, while the French Administration is now engaged in converting the entire Paris system to central battery working.

The extent to which both the administrative and the technical conditions of the telephone business on the Continent have been misrepresented by contributors to the Press, and the general interest in "the telephone question" at the present time are my excuse for the length of this letter, for which I trust you will be able to find space.

I am, &c.,
HERBERT LAWS WEBB.

35 OLD QUEEN STREET, WESTMINSTER, S.W.,

ELECTRIC DRIVING OF TEXTILE FACTORIES

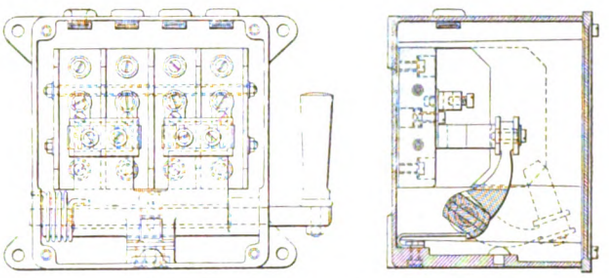
A PAPER on the development of textile electric driving was read before the Dundee Institute of Engineers last Saturday by Mr. J. Shaw (Mill Engineer of the British Thomson-Houston Co.). In looking back upon the history of electrically-driven textile mills, the author called attention to the fact that five years ago the United Kingdom did not contain a single textile mill driven electrically, either from its own generating plant or from outside supply. Two years afterwards, in February, 1905, contracts were entered into to erect the first new textile mill in the United Kingdom to be electrically driven. One mill only, in the meantime, had completely replaced its old gear-transmission by electric-transmission. There are to-day in operation in the British Isles electrically-driven mills aggregating about 26,000 b.h.p. in motors. This amount is being added to every day. Since the first completely electrically-driven mill in the world was equipped (viz., the Columbia Mill, in South Carolina, equipped in 1894), 70,000 b.h.p. in motors had been installed in America. There is, to-day, a total of about 225,000 h.p. in that country. Electrical-driving has therefore progressed during the last five years 26,000 b.h.p. in the United Kingdom, and some 155,000 b.h.p. in the States. The progress on the Continent has been equally remarkable.

He said that electrical-driving in this country was now in relation to rope-driving, in the same position the latter occupied 20 years ago in relation to gear-driving. The same strenuous opposition which was offered to rope-driving had been experienced against electrical-driving. Rope-driving had demonstrated its practical utility and was accepted as better than gear. Electrical-driving was forcing itself into recognition as strongly as rope-driving forced itself 20 years ago. The experience of the last few years had done much to dispel the opposition originally experienced, and it was not too much to say that ultimately electrical transmission would be universally adopted.

The advantages to be gained by electrical-driving were classified as follows, and those coming under each heading were discussed at length :—

(*a*) Maximum steadiness and uniformity of speed, resulting in improved quality and greater quantity of production in a given time. (*b*) Elimination of rope race, shafting, belts, ropes, and gears, reducing power-transmitting devices to an absolute minimum. (*c*) Less wear and tear on driven machinery, due to steadier speed. (*d*) Flexibility and facilities for independent operation and extensions. (*e*) Allocation of correct proportion of power costs to each department. (*f*) Facility for tracing and eliminating sources of undue absorption of power. (*g*) Centralisation of power generating plant.

The steadiness of the steam turbine as a source of power was emphasised, and the following advantages of taking current from central power-stations rather than isolated plants were discussed :—(*a*) Continuity of supply and freedom from stoppage. (*b*) Reduction of original capital outlay. (*c*) Extensions can be carried out at the smallest expense. (*d*) Specialisation of mill management in textile work alone. (*e*) Freedom from engine, boiler, and gearing troubles.



It was pointed out that of the total amount of textile electrical-driving now running in Lancashire and Yorkshire, more than one-third is driven from the mains of power supply companies or municipal corporations, and the present tendency appears to be to further development on these lines.

In dealing with the question of the probability of stoppage of supply under different conditions, Mr. Shaw gives an example from a record of the first cotton mill in the United Kingdom to be driven in this manner. The mill is supplied from a power-station, in which all the plant was new and untried. The mains, sub-station plant, and mill equipment were also new. In other words, the whole of the plant was new, and it could scarcely be expected that hitches might not occur. During the first six months' run the total stoppage in the mill amounted to 5 hours 57 minutes. Of this amount, faults at the power-station and on the mains and substation accounted for 3 hours and 27 minutes. Stoppages on the mill equipment amounted to 2½ hours. During the same period, in another mill of similar size, owned by the same authority, but driven by means of rope-transmission, the total stoppages amounted to 41 hours, and the average stoppages for the five previous half-years in this mill amounted to 11¼ hr. The total stoppages from all causes during the 12 months run, ending December 31st, 1907, of the electrically-driven mill, amounted to only three hours. This record speaks for itself.

A NEW IRONCLAD SWITCH

THE accompanying drawing shows details of a new switch which has been recently introduced by Messrs. A. Reyrolle & Co. with the object of meeting the demand for a flame-proof, rain-proof, double-break, quick-release switch of substantial construction for use in exposed positions, mines, factories, &c.

With regard to the construction of this, it should be noticed that the arms carrying the switch blades are all cast in one piece integral with the sleeve *A*, which is loose on the shaft. The cam *B* is pinned to the spindle, and in putting the switch to the "on" position it engages with the sleeve at the point *C*. On

DOUBLE-POLE IRONCLAD SWITCH.
Scale : ⅛th full size.

the sleeve *A* there are also two projections shown at *D* which are engaged by the spring *E* in the "full on" position only. In switching off, the cam *B* depresses the spring *E*, thus releasing the catch, then engages the sleeve at the point *F* and starts withdrawing the blades, after which the spring *G* takes charge, giving a very quick break. The wearing parts of this switch are built up from small pieces, which are very easily renewable, with the result that the necessary spare parts, for even a large installation, would cost a very small sum only. Having in view the ease with which the parts may be renewed, it was not thought necessary to embody sparking contacts in the design. The switch, which is rated at 25 amps., is also made in the three-pole type.

SOME NEW TELEPHONE DESIGNS

THE General Electric Co.'s new telephone catalogue (the tenth edition), published last week, shows that several interesting modifications in detail have been made in the company's designs. Among the more interesting of these is the development that has been made in the employment of "concealed" terminals. Not only in the case of the best exchange

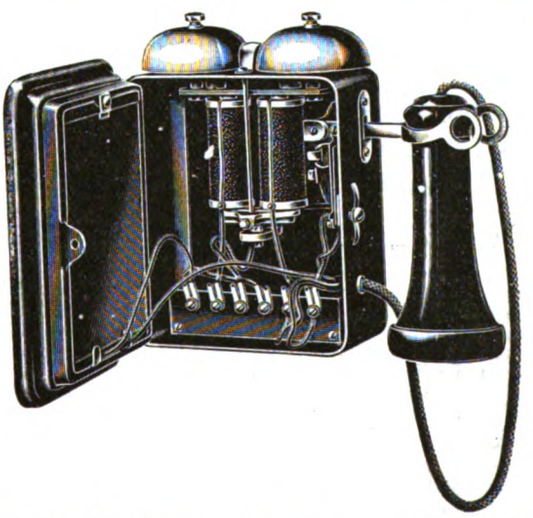


FIG. 1.—C.B. EXCHANGE INSTRUMENT IN STEEL CASE AND WITH CONCEALED TERMINALS.

instruments, but also in some of the cheaper house telephones a hinged back-board is provided, and the terminals are within. A central battery exchange instrument of this type is shown in Fig. 1, which also embodies another new feature, namely, a case made of enamelled mild steel instead of wood.

We also illustrate a new portable telephone for use in tramway feeder pillars. Fig. 2 shows box, fitted with a pair of jacks, which is fixed in the pillar, and Figs. 3 and 4 the hand combination telephone, which is carried by the tram

Digitized by Google

conductor. The tabs at the end of the cord are joined permanently to a two-pin plug, which is pushed into the jack. The case of the instrument is of aluminium. The terminals of the "plug-box," connected to the jack, are fitted with small locking screws, preventing the nuts from being completely removed and lost. These, together with the jacks themselves,

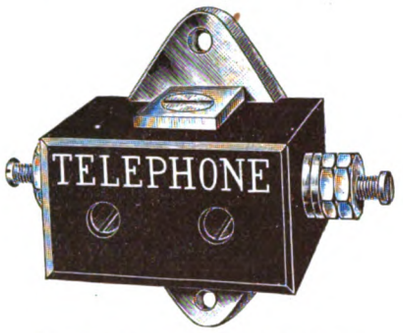

FIG. 2.—PLUG-BOX FOR TRAMWAY FEEDER PILLARS.

are mounted in a solid ebonite block, which is fixed to a cast-iron base. Several other types of tramway telephone and accessories are listed, and the catalogue also includes varieties of water-tight instruments for mining, ships, and engine-house use, telephones for rifle ranges, military telephones, as well as affording an embarrassingly rich choice of instruments for domestic installations and exchange service. We also notice a

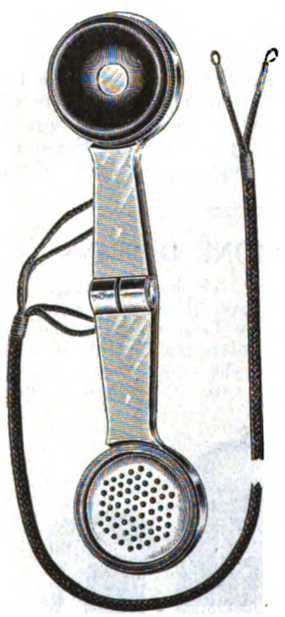

FIG. 3.—ALUMINIUM TRAMWAY TELEPHONE, OPEN.

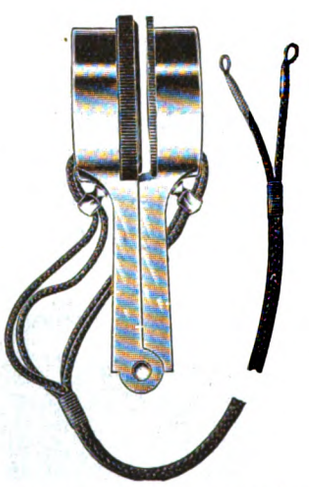

FIG. 4.—ALUMINIUM TRAMWAY TELEPHONE, CLOSED.

thermostat for fire-alarm purposes designed by Lieut.-Col. Fox, of the Salvage Corps. The company inform us that they are prepared to manufacture and erect complete central battery exchange switchboard equipments, and some designs are illustrated in the list. The General Electric Co. have always been famed for the completeness of their catalogues, and this new telephone catalogue fully maintains their reputation in this respect.

A New Metallic Filament Lamp.—The International Electric Co., of 55 Redcross Street, London, E.C., are to-day placing a new metallic filament lamp, the "Orieco," on the market. This lamp is supplied in sizes of from 32 to 50 c.p. at 70 to 130 volts. The efficiency is 1¼ watts per British candle-power, and it is claimed that during an average life of 1,000 hours there is no falling off of efficiency. The lamp may be employed both on continuous and alternating currents. Its price is 4s. As in the case of the majority of other metallic filament lamps, the lamp must be hung in a vertical position. In connection with the supply of the lamps, an interesting fact to be noted is that the suppliers, while paying carriage in the case of consignments of over 50, and making no extra charge for packing, undertake to give credit for breakages if they are notified at once, and the damaged lamps returned forthwith.

CATALOGUES AND PAMPHLETS RECEIVED

ADVERTISING SIGNS.—The Sun Electrical Co., of Charing Cross Road, illustrate a number of effective new patterns of illuminated signs, including their patent kaleidoscope colour-changing sign, and a novelty which immediately attracts attention known as the "winking pup," consisting of an effigy of a particularly knowing yellow puppy, with a lamp in the interior of his head which is connected with a thermoblink flasher, so that he winks his left eye. A very simple form of thermal flasher is listed as well as motor-driven flashes for more complicated effects.

A leaflet received from the Technical Art Co., of Newcastle, whose sole selling agents are Messrs. Jarvis Bros., Ltd., of Middlesbrough, describes a circular sign with a conical back containing the lamps and flashing apparatus. A "duplex" arrangement can be fitted so that different lettering is lighted up alternately.

ENGINEERING SPECIALITIES.—The new catalogue issued by Messrs. Michael Pal & Co., of Parliament Mansions, Victoria Street, S.W., gives particulars of quite a large variety of machinery and appliances of use to engineers. The oil-saving and waste-cleaning apparatus includes separating, washing, and drying machines for oily waste and cloths and oil filters. Fans driven by diminutive steam turbines and water power, which may be useful where electric power is not available, are also listed. Other appliances comprise turbine type boiler-tube cleaners and steam soot and dust blowers. A useful item is an electromagnetic lamp holder, which can be made to adhere to any iron or steel object. Lubricating rotary pumps and automatic chain valves are also dealt with, and illustrations given of dynamos and motors, for full particulars of which reference must be made to a separate list. Attention should also be called to a particularly compact form of pillar type electrically-driven grinding and polishing machines, fitted with twist drill attachment and a pendulum swinging holder, which allows a steady universal movement to be given to the tool while grinding.

INCANDESCENT LAMPS.—A coloured folding card is to hand from "Cryselco, Ltd.," with a representation of an incandescent lamp and a holder on the two halves of the card, so arranged that the collar of the lamp fits into the holder in a very realistic manner.

LIGHTING, POWER, AND HEATING APPARATUS.—The newest batch of leaflets issued by the Electric and Ordnance Accessories Co., Ltd., of "Stellite" Works, Birmingham, cover a considerable range of electrical apparatus. Taking first those dealing with arc lamps, we find a description of the "Victor" flame arc lamp, which has a remarkably simple mechanism consisting of clutches with separate coils for each carbon, so that there are actually only two moving parts. Special care is taken to ensure that fumes are excluded from the interior of the lamp. Other leaflets contain details and coloured illustrations of standard enclosed and miniature "Victor" arc lamps. The lists of Stellite dynamos and motors cover four pole semi-enclosed machines up to about 20 kw. The most attractive of the set of leaflets, from an artistic point of view, are those devoted to electric heaters, which contain some well-executed examples of colour-printing. A large number of designs of "Eclipse" heaters of the induced draught type are illustrated, in which a current of heated air rises from perforations at the top of the case as well as radiators of the lamp type.

MOTOR TESTING BRAKES.—A revised list from Messrs. Morris and Lister, of Coventry, describes the latest pattern of their eddy current testing brake. As compared with the earlier forms of this mechanical construction has been simplified, and at the same time the apparatus has been made more suitable for continuous working without overheating. This has been effected by doing away with the outer pole rings and substituting a disc of iron, attached to each copper disc itself, on which is mounted a series of vanes which promote radiation from the heated disc and at the same time induce a current of air to circulate round the exciting coils. For high-speed work the brake is frequently fitted with ball bearings. The sizes listed range from 3 to 35 h.p. on continuous rating. Special control panels are also included in the list.

PORTABLE AND SEMI-PORTABLE ENGINES.—A magnificently printed illustrated catalogue of portable and semi-portable engines of high class, complete with boilers, and arranged for superheated steam, has been issued by Mr. R. Wolf, who has made a speciality of machinery of this class. A feature of the boilers, which are of the fire-tube type, is that the whole tube system and superheater can be easily taken out and replaced, so that the removal of scale is much facilitated. The arrangement of the superheater immediately at the end of the tubes in the smoke-box ensures a very good efficiency. It is impossible to recapitulate here the features of all the types listed, but a good idea of the economy of the sets can be obtained from the following figures of coal consumption:—Single-cylinder engine of 24 B.H.P., 2·12 lb. of coal per B.H.P. hour; compound condensing engine of 100 B.H.P., 1·37 lb. per B.H.P. hour;

Digitized by Google

tandem compound condensing engine with two superheaters of 55 B.H.P., 1·23 lb. per B.H.P. hour. We are also informed that the same makers have recently obtained a figure of 1·11 lb. per B.H.P. hour for a 500 h.p. tandem compound semi-portable set. These engines are particularly suitable for temporary generating stations and extensions, and their variation in speed is guaranteed to be within 1 in 150.

STANDARDISING AND TESTING INSTRUMENTS.—Messrs. R. W. Paul's new instrument catalogue takes the useful form of a number of separate sheets bound together in a cover, so that they can easily be added to. A very large variety of resistance boxes, slide wire resistances, and bridges, variable carbon and other rheostats, are listed, in addition to moving coil "single pivot" galvanometers and measuring instruments. Further forms of galvanometer include the well-known Ayrton-Mather moving coil type, Mr. A. Campbell's standard galvanometer, and Paul's marine galvanometer. Another group of instruments is the series of Duddell-Mather standard wattmeter and anti-capacity gauge resistances. The special instruments for alternating current work include Cohens barretter, the Ayrton-Mather electrostatic voltmeters, and Campbell's vibration galvanometer, and standards of mutual induction.

STEAM TURBINES.—We have received a pamphlet from Messrs. Willans & Robinson, Ltd., describing their system of "mixed pressure" turbines, in which, by specially arranged valves and governor gear, the same turbine can act either as an exhaust steam turbine or as a combination between the two when the supply of exhaust steam falls below the normal.

TELEPHONES.—The Sterling Telephone and Electric Co. have sent us the seventh edition of their long list of telephones and accessories, fire alarms, mining bells, and exploders, &c.

WATER SUPPLY, PUMPS AND ACCESSORIES.—A collection of leaflets from Arnold Goodwin & Sons, of Southwark, deal with their compressed-air system of pumping water, and announce the opening of new departments for hydraulic and general engineering repair work. Other specialities are the "Beatall" patent piston rings, and a series of self-restraining worm-geared lifting blocks and "suspended lift-ways."

ELECTROCHEMISTRY AND ELECTROMETALLURGY

IN the *Comptes rendus de l'Académie des Sciences*, 1907, 645, C. Matignon describes the preparation of aluminium carbide, C_3Al_4. A mixture of fine aluminium powder and lamp black is placed in a Perrot electric furnace and strongly heated; the reaction between the metal and carbon takes place quite smoothly. The heating can also be carried out with an acetylene-oxygen flame. Another method for preparing the carbide is to heat hexachlorobenzene, C_6H_6, in a sealed tube with aluminium to 225°. The carbide gives off methane when acted upon by hydrochloric acid,

$$C_3Al_4+12HCl=3CH_4+4AlCl_3.$$

Time after time patents containing processes for the electroplating of aluminium have been published. but we seem to get very little nearer a successful process for plating upon this

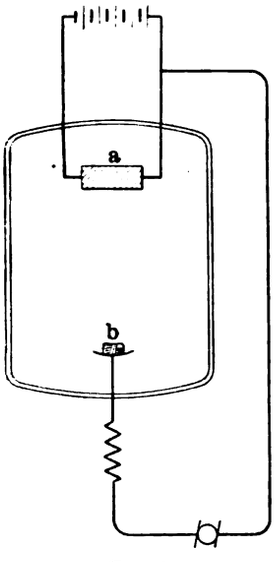

FIG. 1.

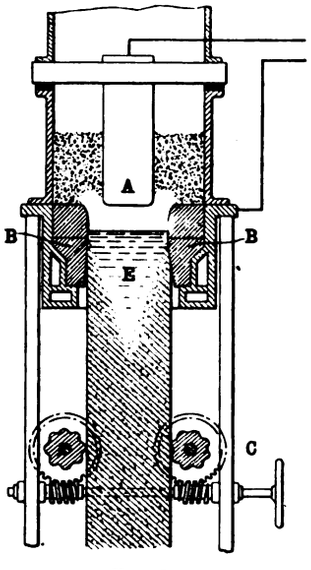

FIG. 2.

metal. According to the *Electrochemische Zeitschrift* of January, the well-known firm of Langbein-Pfanhauser in Leipzig have now worked out a process which is entirely successful. Unfortunately, what the process is is kept a secret.

In the electrolytic production of aluminium by the electrolysis of alumina dissolved in fused cryolite, the electrodes employed are of carbon. In the *American Patent* 872,985 (3/12/07), Henry Spencer protects the use of electrodes of calcium or other carbide. According to Spencer, both the cryolite and alumina take part in the electrolysis, and the electrode is therefore consumed in the following manner:—

$$2AlF_3+2Al_2O_3+3CaC_2=6Al+3CaF_2+6CO.$$

It is usually accepted that in the process as at present worked, only the alumina is decomposed by the current, and that the corrosion of the electrode is entirely due to the action of the liberated oxygen; indeed, great care is taken in the regulation of the voltage in order to prevent the liberation of fluorine. If when calcium carbide electrodes are employed the reaction takes place as above formulated, there seems no reason why the bath should not be started with fused calcium fluoride, since unless cryolite were continually charged in, after a time the bath would become rich in calcium fluoride. Furthermore, as the aluminium fluoride became used up, the alumina alone would take part in the electrolysis. If alumina only took part in the electrolysis, then the electrode would be oxidised as follows:—

$$Al_2O_3+CaC_2=CaO+2CO+2Al.$$

The bath would therefore become choked up with lime, and the resistance would increase. On the other hand, it would hardly pay to continually charge in cryolite, whether artificial or natural.

Up to the present, in order to form reguline masses or filaments of very refractory metals, such as tantalum, it has been customary to compress the powdered metal, and then to cause adherence of the particles by passing an electric current through the compressed mass in an indifferent atmosphere. In the *American Patent*, 873,958 (17/12/07), M. V. Pirani describes a new method of melting the metal in vacuum. An oxide, such as barium oxide, is strongly heated in a vacuum, so that it becomes ionised, there is then no difficulty in striking an arc between it and the substance to be melted. The method of carrying out the operation is shown by the sketch, Fig. 1. *A* is the barium oxide, which can be brought to a high temperature in the vacuum by heating it with the current from the battery *b*. As soon as this has taken place an arc readily springs between the metal to be melted at *a* and the oxide. On a 100-volt circuit the arc can be induced when the oxide and metal are separated by some centimetres, with 50 amperes the metal is very rapidly melted. Either a direct or an an alternating current can be employed.

Calcium carbide is always contaminated with more or less unreduced lime and carbon, and consequently does not yield the same quantity of acetylene as if it were quite pure. J. C. King, in the *American Patent*, 872,351 (3/12/07), describes a furnace for remelting the carbide, and thus getting rid of at any rate a portion of the impurities, and for obtaining it in homogeneous blocks or cylinders. Fig. 2 gives an idea of the furnace which is employed. *A* is the one electrode, and *BB* the other; they both consist of graphite or other form of carbon. The broken carbide is charged in and the current passed. The carbide between *A* and *B* sets up a powerful resistance, and thus becomes strongly heated and plastic. It consequently passes out below *A*, and as it solidifies is drawn continually away by the ratchet arrangement at *C*. For some purposes it certainly would be a great advantage to have the carbide in the form of cylindrical blocks. It would be convenient for packing, and there would be no difficulty in breaking it up as required. The second melting should certainly have a purifying effect.

O. Thallner contributes an interesting, but rather diffuse, article to *Stahl und Eisén*, November 20th and 27th, upon the "Manufacture of High-grade Steel in the Electric Furnace." He considers that the electrode furnace of Héroult is of great use for desulphurising, dephosphorising, and deoxidising. Great credit is due to Héroult, Eichhoff, and Lindenberg, for recognising the possibility of purifying iron and steel by careful manipulation of the slag, and of realising the importance of using pure slags. The electric furnace is generally compared to the crucible furnace but Dr. Thallner considers it as being quite apart from the crucible furnace, where the metal remains molten over long periods. The process in the Héroult furnace consists practically of three stages. In the first place the phosphorus is removed, and the sulphur content reduced; also the carbon is reduced in quantity to about 0·1 per cent. Over-

Digitized by Google

oxidation may take place, and manganese and silicon are removed. The second stage is one of deoxidation, and the third stage is a reduction process. The slag is deoxidised by the formation of calcium and silicon carbide, the iron is thus reduced from the slag, and the slag is in a condition to absorb the sulphur. Dr. Thallner mentions that the life of the Héroult furnace is very good, as shown by experience with a 1½-ton furnace in the Lindenberg works at Reinscheid. This furnace has had 2,337 charges, varying between four and ten per day. Sometimes the charges have been cold, and at other times molten. No repairs of any importance have been found necessary, and any small repairs which were required have been easily carried out at small expense. The furnace is not hard to work, but it requires careful attendance.

ELECTRICAL SCIENCE

British and American

Lecture at the Royal Institution.—Prof. E. Rutherford delivered last Friday evening's discourse at the Royal Institution, the subject being that to which he has so largely contributed, radioactivity. It is four years since his last appearance here, so most of his lecture was devoted to a review of the progress made in that time in radioactive knowledge. Some of his remarks on the most recent discoveries may be mentioned. We learn that of the family of radium the youngest known member is radium-G, formerly known as polonium, and extracted several years ago from pitchblende by Mme. Curie. The transformation product, formerly called radium-E, has of late been shown to be complex, and to consist of substances now called respectively radium-E and radium-F. The lecturer complained that there was little advance in the direction of cheapness of radium, but stated that meso-thorium and radio-thorium, which were extremely active substances, were likely soon to be put on the market and to become useful substitutes, in certain experiments, for radium. Prof. Rutherford then traced the story of the pursuit and capture of the father of radium. This has been named ionium by Boltwood, its discoverer; but as these matters have been already dealt with at a number of dates in this column, we need not recapitulate the lecturer's account of the discovery.

Inductance in Parallel Wires.—The effective inductance for high-frequency currents of a circuit consisting of or comprising two parallel wires is often required with considerable accuracy. For instance, in the measurement of small inductance experimentally, the inductance of the leads used should be known with fair accuracy. In *Nature* of January 30th, J. W. Nicholson gives a formula for the case when the two wires, one the return of the other, are equal in radius. His formula is

$$\frac{L}{l} = 4 \log \frac{c}{a} + \frac{4\mu}{x} \cdot \frac{\mathrm{ber}\, x\, \mathrm{ber}'\, x - \mathrm{bei}\, x\, \mathrm{bei}'\, x}{(\mathrm{ber}'\, x)^2 + (\mathrm{bei}'\, x))^2}.$$

where L is the self-induction of a length l, c the distance between the wires, a the radius of the wires, and μ the permeability of their material. The quantity x is equal to

$$2\pi a \sqrt{\frac{2\mu N}{\delta}}.$$

where N is the frequency of alternation per second; and the functions ber x and bei x are those introduced by Lord Kelvin, and subsequently tabulated. The formula becomes less accurate, as c, the distance between the wires, decreases, and also as the frequency increases or the radius of the wires increases. So far as the first cause is concerned the error is not more than 1 per cent. when the distance between the wires is ten times the radius, or 4 per cent. for five times the radius, or 10 per cent. when the distance is only three times the radius. All the other causes of error in the formula taken together yield very slight error, even with frequencies as high as a hundred million per second, so that the range of application of the formula is extremely wide. When the frequencies become low, the formula given above relapses into the common formula for two parallel wires not too near together, namely,

$$\frac{L}{l} = 4 \log_e \frac{c}{a} + \mu.$$

where the symbols have the same meaning as before. The author mentions that the formula he has deduced for two parallel wires, whose radii are not equal, is much more cumbrous than his formula given above.

Continental

Positive Electrons.—A. Dufour has made an observation which, he says, receives its most obvious interpretation on assuming the existence of positive electrons. The observation in question is described in the *Comptes Rendus* for January 20th. When the Zeeman effect is observed in a direction parallel to the magnetic field, each line is resolved into a doublet of light circularly polarised in opposite directions. The shortened wave-length is emitted by the electrons revolving in the sense of the positive magnetising current. In analogous phenomena observed in the absorption spectra of certain crystals and liquids, the same rule is observed, except in a few anomalous cases observed by Jean Becquerel. But no exceptional behaviour has hitherto been observed in bright-line spectra shown by a glowing gas. Now Dufour describes such an anomalous effect in the arc spectrum of pure calcium fluoride, which, according to Fabry, exhibits flutings with sharp edges at 6036·96 A units (D), 6050·81 (D′), and 6064·49 (D″). In a magnetic field, only D″ shows the normal displacement and polarisation. In D the effect produced indicates positive electrons, though the polarisation is not complete. The other lines indicate a similar effect, though more feebly, and it can also be observed in the corresponding absorption spectra. The author's startling conclusion would be more convincing if the effect were shown on pure elementary spectrum lines.

Slightly Damped Oscillations.—Max Wien produced trains of slightly damped oscillations by loosely coupling a strongly damped primary with a feebly-damped secondary. The decrement of the latter, originally d, is increased to

$$d_2 + \frac{\pi^2 k^2}{d_1 - d_2}.$$

by the coupling, where d_1 is the decrement of the primary, and k is the coefficient of coupling. The second term may be reduced by making the coupling loose (reducing k, and also by making d_1 very large. The effect of doing so resulted in small damping, but since loose coupling means a feeble transmission of energy, large capacities had to be employed in the primary in order to get a perceptible transmission. However, the author found that there is no real necessity of making the coupling loose. When k is large, and the spark crosses in air, the spark increases very rapidly in resistance after the first oscillation. For subsequent oscillations the primary circuit is practically open, and the secondary alone oscillates, and continues to oscillate freely. This means that large amounts of energy can be transmitted without much damping. On working out this new method, the author found himself in a position to bring down the decrement to 0·006.

Magnetic Action of Cathode Rays.—Both Hertz and von Geitler looked for the action of a beam of cathode rays upon a magnet as a counterpart to the action of a magnet upon cathode rays. Neither of them succeeded in tracing such an action, and Hertz considered that this negative result proved the cathode rays to be ether waves and not charged particles. Quite recently E. Klupathy has discovered the effect sought for. It is described in No. 1 of the *Annalen der Physik*. A piece of steel wire was magnetised and suspended vertically above a long cathode-ray tube, so that its north-seeking pole was close to the outer glass surface. It was suspended from one end of a rod hung parallel to the tube, and counterbalanced at the other end of the rod by a copper wire. The rod itself was suspended by a long quartz fibre, so that the N-pole was free to move in a direction at right angles to the tube, and oscillated with a period of 85 seconds. The magnet and suspension were enclosed in a glass case. The deflection observed was in the direction expected, and indicated a current of a few millionths of an ampere. On replacing the tube by a wire traversed by an equal current, the same deflection was obtained. A Wehnelt oxidised cathode did not give this effect, probably owing to the high ionisation of the gas in the tube.

Energy in Three-phase Circuits.—G. Lignana deals, in *L'Elettricista*, of December 15th, with the problem of measuring the total energy in a three-phase system having four wires, three attached to the points of the star and one to its centre. This, as a rule, requires three wattmeters of equal range, connecting the central wire with each of the three-phase wires respectively. The author, on the other hand, puts one wattmeter between wires 1 and 2, another between 1 and 3, and a third, provided with a commutator, between 0 and 1. The last of these may be considerably smaller than the two others. Its reading may be positive, negative, or zero. To avoid ambiguities, the load on one of the wires may be varied so as to make the deflection of the third wattmeter zero. In that case the total energy is measured by the sum of the readings of the other two wattmeters. This implies a dissymmetrical charge and a current in the fourth wire, which, however, may be avoided by means of the commutator on the movable coil of the third wattmeter.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Jan. 30th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

1906 Patents

24,582, BRUCE PEEBLES & CO. & LA COUR. This is a compensated phase transformer for the conversion of single-phase current into polyphase, or *vice versa*, and consists of an ordinary polyphase induction machine with two rotor windings. In the three-phase arrangement, two of the phases of the stator winding are supplied direct from the single-phase circuit, and the third phase is energised by the action of the short-circuited rotor winding. The second winding is an ordinary closed circuit winding with a commutator into which current is supplied from tappings on the stator. This exciting current, the object of which is to prevent the phase transformer from taking a wattless current from the single-phase circuit, can be made to vary with the size and nature of the load, by passing it through a series transformer, the primary of which is in series with the load. Five claims, six figures.

1907 Patents

2,595, ATELIERS THOMSON-HOUSTON. This relates to dynamo-electric machines having good commutation at all loads whilst permitting the direction of rotation to be reversed without displacing the brushes. In compensated machines in which the polarising ampere turns differ from the number of compensating ampere turns, a single winding is so arranged that in every zone of the stator the ampere turns of the winding are equivalent to the geometrical sum of the superposed polarising and compensating ampere turns, and adapted for rotation in either direction without moving the brushes, the ampere turns of each section being equivalent to the geometrical sum of the ampere turns necessary for polarisation, and those for compensation in every zone of the motor. Two claims, four figures.

11,621, BROOKS & AKERS. An arrangement for regulating alternating-current machines when coupled in parallel, and connected to the main bus bars through the primary windings of transformers, the secondaries of which are in closed series. The transformers are combined with reactance coils, through which the machines are connected to an auxiliary bus bar, by means of which the transformers effect the balancing of the load, and the coils counteract the tendency to get out of step. One claim, one figure.

12,923, THE BRITISH WESTINGHOUSE ELECTRIC CO., LTD. This relates to means for neutralising and preventing disturbances in electric circuits caused by electro-magnetic induction from other circuits near to them, and is particularly of service to telephone and telegraph circuits which run parallel to alternating distributing circuits. The E.M.F. is neutralised by means of a transformer, the primary winding of which is connected in series with an auxiliary circuit; the secondary is connected in series with the intelligence transmission circuits, so that its voltages oppose and neutralise those induced in them, by the E.M.F. set up by the power transmission system. If all the circuits have earth return conductors, a part of the current of the power transmission will return through the metallic conductor of the intelligence transmission circuit. The auxiliary circuit should be of the same character as the transmission circuit, and an earth return is provided in the auxiliary circuit. The transformers may be placed at varying distances from each other. Two claims, five figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

22,379, HATFIELD. Voltameters.
25,411, BERRY. Electrically-heated apparatus for cooking.
28,628, CLARK & VLASTO. Electric switches.

1907 Patents

783, CALVERT. Covering, arranging, and mounting electric conductors.
813, DAVIES. Automatic fog-signalling apparatus for railways and the like.
899, HOLLIDGE. Magnetic separators.
919, PARSONS & BALL. Electric clocks.
1,005, LANCASHIRE DYNAMO & MOTOR CO., WARBURTON, & KELSALL. Auxiliary dynamo-electric machines.
1,099, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric switches.
1,099A, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric switches.
1,191, STOCKALL. Electric circuit closing devices.
1,195, HAMILTON. Electrostatic measuring instruments.
1,277, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric switches.
1,279, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Systems of electric motor control.
1,449, FRASER. Braking of electrically-propelled vehicles.
1,499, MANDERS. Production of continuous electrical oscillations for therapeutic purposes.
3,432, EDGAR & EDGAR. Electric switches.
3,633, BRITISH THOMSON-HOUSTON CO. & HOLDEN. Electric meters.
4,081, ELECTRIC IGNITION CO. & HALL. Electric ignition-apparatus of internal-combustion engines.
4,183, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Protective devices for electrical apparatus.
4,782, BROADBENT. Electric switches.
5,424, DAMSEAUX. Electric incandescent lamps of variable intensity and holders for the same.
5,502, BOLTON & COVENTRY WATCH MOVEMENT MANUFACTURING CO. Electrical switches.
6,266, BRITISH ELECTRIC PLANT CO. & OELSCHLAGER. Commutation of dynamo-electric machines.
7,279, ANGOLD & MAXIM ELECTRICAL CO. Electric arc lamps.
9,240, MÖLLER. Electric time-pieces.
9,337, NORTH & POHL. Electrolytic electricity meters.
9,991, ELLIOTT. Multiple sockets for incandescent lamps.
10,406, W. T. HENLEY'S TELEGRAPH WORKS CO. & NICHOLS. Junction boxes for electrical cables.
10,469, HAHN. Electrical vapour apparatus.
10,786, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electrical signalling systems and apparatus therefor.
11,616, FLUEGELMAN. Electro-magnetic counters.
11,717, SIEMENS & HALSKE AKT.-GES. Metallic filament lamps.
11,823, LAKE (*Stone*). Devices for amplifying telephone currents.
12,356, STEPANOW. Method of signalling by means of electric lights and apparatus therefor.
12,531, TURNER. Electric connectors or couplings.
15,755, ANKER. Ear-guard for telephone receivers.
16,251, HINSKY. Insulating conduits for electric wires.
17,079, GSCHWEND. Medical electric heating appliances.
17,722, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electric controllers.
17,968, CLASSEN. Process for electrolytic metallic coating upon metals.
17,969, CLASSEN. Electrolytic process for the production of metallic dark coatings upon metals.
18,921, BRITISH INSULATED AND HELSBY CABLES, LTD., & HARRISON. Electric telegraph apparatus.
19,800, LAKE (*Fabrik Elektrischer Zunder*). Dynamos especially applicable for exploding electric igniters.
20,650, HARTENSTEIN. Electric furnaces.
20,948, SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*). Method for reducing disturbances in telephone and telegraph wires.
21,862, RICKMANN. Armature for magneto-electric igniting apparatus.
22,322, JONES. Brakes for tramway and railway vehicles.
24,028, WOLFRAM LAMPEN AKT.-GES. Process for decarbonising tungsten filaments containing carbon or carbide.
26,130, BREWER (*Taylor*). Electric furnaces.
26,846, ALLGEMEINE ELEKTRIZITÄTS GES. Arc lamps.

Complete Specifications open to Public Inspection before Acceptance, under the Patents Act, 1901.

1907 Patents

5,506A, LAMME. Connections for dynamo-electric machines.
16,854, TARDIEU. Telephonic apparatus.

1908 Patents

327, LERTOURNÉ. Electric speed indicators.
328, LERTOURNÉ. Electric motors.
660, ALLGEMEINE ELEKTRIZITÄTS GES. Multiple-rate meters.
661, ALEXANDERSON. Dynamo-electric machine.
700, AGRELL. Electric type printing apparatus.
889, SEIBT & AMALGAMATED RADIO TELEGRAPH CO. Radio-telephony.

Expiring Patent

The following patent expires during the current week, after a life of fourteen years:—

No. 3020, February 12th, 1894. FREDERICK TUDSBURY. Improvements in electrical machines, to increase the output and efficiency of induction machines, and particularly applicable to machines of the "Wimshurst" type.

For LOCAL NOTES, &c., see pp. 213 to 220

LOCAL NOTES

ABERDEEN: *The Tramway Service.*—Complaints have been made by the residents along certain tramway routes as to the service being behind schedule time. The tramway manager has submitted a statement which shows that for sixteen weekdays the cars on these routes were only one-sixteenth of a minute behind schedule time, and the committee have accordingly agreed that there has been no foundation for the complaint. Mr. J. D. Laird, the traffic superintendent, having secured a position with the Halifax Corporation, the General Manager has arranged that the work of superintending the traffic shall be carried on without an increase of staff.

Electricity Supply.—The Electrical Engineer has received an application from the Admiralty for a supply of electric power to the proposed wireless telegraph station which is to be established at Aberdeen. A schedule of prices is to be drawn up. During December, 1907, 696,771 Board of Trade units were generated compared with 760,865 during the corresponding month of 1906.

Purchase of Deeside Co.'s Undertaking.—The Corporation electrical engineer, Mr. J. A. Bell, has prepared a report showing the capital expenditure of the Deeside Electricity Supply Co., without any allowance for depreciation, sinking, or reserve funds. The nominal capital of the company was £10,000, and the price paid by the company in December, 1905, to Messrs. Lowdon Brothers for the undertaking was £7,500. Subsequently, the company installed plant to the value of £1,712, and a workmen's cottage had been erected at a cost of £330, making a total of £9,842. The valuation Mr. Bell made for the Corporation of the undertaking as a going concern was £6,137, which, however, did not include anything for the cost of the company's provisional order, or the flotation of the company, amounting to £667, or for good-will, &c. The company's profit for the year ended December, 1906, was £283 3s. 9d., from which was deducted, interest £54, and proportion of preliminary expenses, £36 7s. 8d., leaving £192 16s. 1d. as the net profit for the year. The units sold for the year ended December, 1907, show a 10·4 per cent. increase over the preceding year. The undertaking, as taken over by the Corporation, had 141 consumers. It will be remembered that the Corporation sought and obtained powers to purchase the company's undertaking in a Bill last session.

ACCRINGTON: *Tramway Supervision.*—The General Works Committee have agreed to take over the supervision, maintenance, and repair of the tramways, the cost thereof to be chargeable to the tramways' department.

BATH: *Purchase of Electric Light Works.*—The arrangements between Mr. Schenk, which were made some time ago on behalf of the Somerset and District Electric Light Co. and the Corporation to purchase the electricity works, expires at the end of March. Up to the present the necessary capital to carry out the purchase has not been obtained, and if the agreement has not been put into force by the time mentioned, the deposit of £2,500 will be forfeited. In the meantime a suggestion has been made that the works should be leased or the option to purchase shall be further extended.

BLACKBURN: *Tramway Statistics.*—The Borough Treasurer's statement relating to the working of the Corporation electric cars for the nine months ended December 31st shows total expenditure amounting to £28,492, averaging 8·06d. per car mile, and receipts £47,424, averaging 13·42d. per car mile. The sum of £18,931 is carried to net revenue account, and after payment of sinking fund and interest, the net profit on the nine months' working is returned at £3,362 16s. 2d.

BRIGHTON: *Tramway Undertaking.*—A resolution is down to be moved at the next meeting of the Corporation recommending the Tramways Committee to obtain expert advice as to the present system of running the cars with a view to improving the service generally.

BURY: *Proposed New Electricity Works.* In response to a request from the Bury Chamber of Commerce, the Corporation has decided to supply details of the scheme for building a new generating station. No application has yet been made for the necessary borrowing powers.

CANADA: *Electric Railway Developments.*—It is stated that progress is being made in connection with the company which proposes to spend £2,000,000 upon electric railway and other enterprises in Canada. Engineers are said to be engaged in making the necessary surveys in connection with electric railways in the rural districts of Ontario and Montreal. It is also proposed to take the Toronto Street Railway in hand and greatly improve it.

CARDIFF: *Telephone Call Boxes.*—The National Telephone Co. have opened six public call boxes in the Docks district, the charge being 1d. for communication with subscribers connected to any exchange in the Cardiff area, and 2d. per call to certain places beyond.

Tramway Receipts.—Mr. Arthur Ellis, the Tramways Manager, reports that, based upon nine months' actual expenditure from figures supplied by the City Treasurer, he estimates that at the end of the year there will be a profit of £15,000 from the tramway system, as against £4,000 last year.

COLNE: *Road Repair by Tramway Co.*—A dispute between the Town Council and the Colne and Trawden Light Railway Co., on a question of principle regarding the repair of the roadway just outside the light railway track, is to be submitted to arbitration.

DERBY: *Tramway Extensions.*—Preliminary runs have been made over the recently converted Nottingham Road route, and it is anticipated that the line will be opened for traffic this week.

DORCHESTER: *Provisional Order Revocation.*—The Board of Trade has revoked the Dorchester Electric Lighting Order, 1901.

DUNFERMLINE: *Electricity Supply.*—After considering the report made by Sir Alexander Kennedy, in which he advises the transfer of their electric lighting provisional order to the Fife Electric Power Co., the Town Council has requested Sir Alexander to ascertain upon what terms the company would acquire the order.

EASTBOURNE: *Assessment of Electricity Works.*—As the result of a conference between the Electric and Lighting Committee, and the Assessment Committee it has been agreed that the assessment of the electricity undertaking shall be increased from £1,420 to £3,020.

FINCHLEY: *Extensions of Electric Lighting Area.*—As we have already reported, a ratepayers' meeting has rejected the clause in the Corporation's Bill for enlarging the electric lighting area. The matter came up at a special meeting of the Council last week, when this decision of the ratepayers was confirmed.

HALIFAX: *Workmen's Tramway Fares.*—In reply to a communication from the Board of Trade, the Tramways Committee state that the delay in working out a scheme of workmen's fares to meet the wishes of the ratepayers, who memorialised the Board of Trade, has been due to the recent changes in the managership.

HANWELL: *Tramway Nuisance.*—At the last meeting of the District Council a letter was received from the Board of Trade in answer to the Clerk's letter, regarding the noise of the trams, stating that so far as the section of the Tramway Act relating to the obligations of the London United Tramways Co. were concerned, the Board was not prepared to order any inspection, since it did not appear to them that an inspection could determine the question whether the track was being maintained with such materials and in such manner as the road authority should direct, and to their satisfaction. The Board asked whether the Council alleged that the company had failed to comply with the provisions of the former section, viz., that they should "maintain the track so as not to be a danger or an annoyance to the ordinary traffic." The Clerk was directed to reply that the state of the track was both a danger and annoyance to the ordinary traffic.

HULL: *Telephonic Intercommunication.*—Arrangements have now been completed for intercommunication between the Corporation telephone service and that of the National Telephone Co. The company will in future abandon the present transfer system and pass all calls direct.

Electricity Finances.—At the meeting of the Electricity Committee on Thursday last week it was decided to transfer the sum of £20,362, the amount of the present reserve fund, towards extinguishing the capital expended beyond the amount sanctioned by the Local Government Board. It was stated that the amount sanctioned was £334,365, whilst the sum actually spent at March 31st, 1907, was £355,321. This action on the part of the committee has been brought about by a suggestion made by the Local Government Board Inspector at the recent inquiry for further loans when dealing with the excess expenditure.

ILFORD: *Tramways Intercommunication.*—The Board of Trade have communicated with the Council, asking whether any decision has been come to regarding the proposed interrunning of tramcars between the Ilford and Barking tramways systems. The Tramway Committee now state that it is impossible to arrange such a system of intercommunication between the two systems, but recommend that an offer be made to run Ilford cars over certain of the Barking lines, the conditions being that the whole of the receipts, whilst the cars are running on the Barking section, be handed to the Barking Council, less the Ilford Council's actual working expenses.

INDIA: *Progress Under the Electricity Act.*—The Calcutta *Statesman* gives the following list of applications for electricity supply and tramway powers under the Indian Electricity Act for authority to establish electrical undertakings in India, with the progress made in each case.—*Calcutta*—Electricity supply and tramways scheme in operation. *Darjeeling*—General electricity supply, in operation. *Barrackpore*—General electricity supply, in operation. *Howrah*—General electricity supply, suction gas plant, in operation. Tramways scheme, Diesel engines, in progress. *Coal Fields District*—Power-licence granted. *Hooghly River District*—Power-licence granted. *Dacca*—General electricity supply, in operation. *Cawnpore*—General electricity supply and tramways, in oper-

Digitized by Google

ation. *Lucknow*—General electricity supply and tramways, in progress. *Benares*—General electricity supply and tramways, licence granted. *Amritsar*—General electricity supply, licence granted. *Delhi*—General electricity supply and tramways, in operation. *Bombay*—General electricity supply and tramways, in operation. Hydro-electric long-distance power transmission, licence granted. *Nagpur*—General electricity supply and tramways, in progress. *Jubbulpur*—General electricity supply and tramways, licence granted. *Secunderabad*—General electricity supply and tramways, licence granted. *Madras*—electricity supply and tramways schemes, in operation. *Rangoon*—General electricity supply and tramways, in operation. *Mandalay*—Tramways, in operation.

KNARESBOROUGH.—*Electricity Supply.*—The Council's attention having been called to the decision of the Harrogate Cortention having been called to the decision of the Harrogate Corporation to apply for a Provisional Order extending the area of their present electricity undertaking to include Knaresborough, it has been decided to take no action in the matter.

LANCASTER: *The Tramway Question.*—A discussion took place in the Town Council last week with regard to the continued decrease in the local tramway receipts. The question of converting the lines to electric traction in conjunction with the Morecambe tramways has received attention from time to time, and the suggestion was again raised. No action was taken with regard to the matter, however.

LEYTON: *North East London Railway Act.*—The Urban District Council has resolved to call the attention of the Board of Trade to the serious delay in putting into operation the powers granted by the North East London Railway Act, 1905, and the serious effect entailed on the district by this delay.

Supply of Electricity Bill.—The Legal and Parliamentary Committee have recommended that the seal of the Council should be affixed to a memorial to the Prime Minister and the Board of Trade in favour of the reintroduction of the Supply of Electricity Bill.

LITTLE LEVER (LANCS.): *Tramway Extension.*—A deputation from the Little Lever District Council has been appointed to wait upon the Bury Corporation to ask that authority to provide tramways in that district.

LONDON: *Camberwell: Local Firms' Tenders.*—At the last meeting of the Borough Council, a resolution was moved to the effect that in the case of tenders received from local firms, a reduction of 10 per cent. should be made for the purpose of comparison between these tenders and those coming from firms whose works are outside the Borough. In the event of this reduction of 10 per cent. making the local tender the lowest, the mover of the resolution suggested that it should be accepted. The object was, he said, to induce firms to set up works in Camberwell, and so increase the rateable value of the district. The motion was almost unanimously rejected.

City of London: Audit of Electric Supply Companies' Accounts.—The Court of Common Council has decided to support the Bermondsey and other Borough Councils in protesting against the Board of Trade proposal to dispense with the official audit of the accounts of electric lighting companies. Further information concerning this matter was published in our issue for January 23rd, page 112.

MORLEY: *Proposed Purchase of Tramways.*—At a meeting of the Town Council on Monday, a resolution was carried committing the Council to the purchase of the light railways authorised to be constructed in the town. The lines will subsequently be leased for a term of 28 years at a rental of £3,000 per annum.

NEWPORT (MON.): *Parcel Carrying on Tramcars.*—The Electricity and Tramways Committee looks favourably upon the suggestion of introducing a system of carrying parcels upon the tramcars, and inquiries are being made into results obtained in this connection in other towns.

OXFORD: *The Dolter Surface Contact System.*—A reply has been sent to the Town Clerk by the engineer to the National Electric Construction Co. to the report upon the Dolter surface contact system made by the consulting engineer to the Corporation, Mr. Stephen Sellon (ELECTRICAL ENGINEERING, January 2nd, p. 28). Mr. E. A. Mitchell says that Mr. Sellon is not very definite as to what he means by "experimental stage." Did he suggest that no progress should be made, and that no endeavour should be made to eliminate any small defects? He had, from the local paper, taken the number of passengers carried on the front line from January 26th, 1907, to November 16th, 1907—40 weeks—and the total is 2,255,135. If an efficient service of cars had not been maintained it would have been impossible to have carried this number of passengers over so short a route. Mr. Sellon had evidently overlooked the fact that at Hastings the Board of Trade have given the Dolter system a clean certificate, that ever since they opened there they have had to report every live stud, and that, owing to danger from salt-water flooding the track, the Board of Trade inspector made a special test of the effect of salt-water, and then defined that a "live stud" should mean any stud reading over 18 volts to earth. Could Mr. Sellon point to any system where such stringent requirements have been laid down? Mr. Mitchell also asks where Mr. Sellon obtained his information from regarding the patrol of four men on the look-out for live studs. Certainly not from observation. As a matter of fact, at the present moment, only two men were on the track at any one time. He did not know how Mr. Sellon arrived at his figure of "25 per cent. more current than the average electrical undertaking." He had figures of current consumption obtained from the Hastings Tramway Co., on November 22nd, 1907, which showed an average of 1·196 units per car mile. It must be admitted by any unbiassed electrical engineer that a track impregnated with salt-water, as at times at Hastings, would give more surface leakage than a similar track which has only to deal with rain-water, and he had, therefore, no hesitation in saying that the current consumption per car mile along the front at Hastings was excellent, and, in his opinion, would not be improved upon by the overhead system. In conclusion, Mr. Mitchell points out the Dolter system at Hastings has been installed under very onerous conditions, the principal being that the line was to be put down at the company's expense for a period of twelve months, the Hastings company to take it over and pay for it upon the expiry of that period, if it was satisfactory. Certain guarantees were also given as to the efficient working, and so on, and these guarantees he claimed to have fulfilled. Having regard, therefore, to the amount at stake, it was only natural that with a new system, which had not been working in this country before, the directors should err on the side of safety, and the result of experience proved that the staff could have been reduced considerably. It is now stated that the installation has been taken over by the Hastings company as satisfactory.

PENGE: *The London Power Bills.*—Reporting upon the London and District Electric Supply Bill and the London Electric Supply Bill (Joint Committee), the Town Clerk states that neither appears to adversely affect the interests of Penge, and the Council accordingly does not deem it necessary to take any action with regard to opposing these measures.

POTTERIES DISTRICT: *Tramway Fares.*—The North Staffordshire Trades and Labour Council and the Tunstall Education Committee are reviving the agitation against the increase of workmen's fares and the price of weekly tickets. The Fenton and Stoke Urban District Council and the North Staffordshire Chamber of Commerce are also taking the matter up, and making representations to the British Electric Traction Company.

RICHMOND: *West London, Barnes, and Richmond Tramways.*—Mr. H. B. Renwick and Mr. Stephen Sollon, representing the promoters of the West London, Barnes and Richmond Tramways, met the Tramways Committee of the Borough Council on the 29th ult., with the object of agreeing to terms.

SOUTH SHIELDS: *The Tramway Staff.*—The Tramways Committee has submitted a report to the Corporation to the effect that, in view of serious difficulties which have arisen from time to time between the tramway manager and the car-shed superintendent, and the apparent impossibility of their being able to work together to the advantage and satisfaction of the committee and the undertaking, and to the fact that the machinery and the cars have not been maintained in such a condition of order and repair as might have been, the committee deem it advisable to request the car-shed superintendent to hand in his resignation. The resolution has been adopted.

SUNDERLAND: *Tramway Statistics.*—The Tramways Committee have presented a statement showing the estimated expenditure and revenue up to March 31st, 1908, for the purpose of fixing the amount which will be available for the borough rates. The actual figures for the year, however, will not be available until April. Owing to the extremely bad state of trade and the distress in Sunderland during the past year and at the present time, the receipts have suffered a considerable drop, and are still going down. According to the statement above referred to, the income for the year ending March 31st, 1908, is estimated at £71,286 14s.; the traffic expenses amount to £18,959; general expenses, £5,172 3s.; general repairs and maintenance, £4,110; power expenses, £12,840; deducting interest on loans, £8,563 16s.; sinking fund, £9,370; reserve and renewals fund, £6,200, and various other items, leaves a balance available for the Borough funds of £4,288.

TORQUAY: *Tramway Extensions.*—Representations are being made to the Town Council objecting to the proposal of the Tramways Company to delay construction of the tram lines along the sea front until after Easter. It is pointed out that the construction of tramways in this part of the town during the season will be a serious inconvenience and annoyance to the visitors.

WALTHAMSTOW: *Auditor's Criticisms of Electricity Accounts.*—In his report upon the electricity accounts for the year ending March 31st, 1906, the District Auditor, Mr. D. H. Boggis-Rolfe, makes some strong remarks upon the manner in which the accounts have been kept, and goes into detail as to items which should have been charged to revenue, but which are charged to capital. The gross profit shown was £10.550 8s 4d., with a net available profit of £171 19s., this, together with £1,302 10s., the balance brought forward from last year-making £1,474 9s. 4d., has been carried to the relief of rates. The auditor regards this action as absolutely unjustifiable. Likewise the account of stock in hand is criticised and the certifi-

Digitized by Google

cate given by the Electrical and Tramways Engineer, who was not appointed until May, 1906, is considered valueless. Complaint is also made that the Council continues to use tramways money for electric lighting purposes, and that no certificates have been furnished as to the state of repair of the works. The auditor arrives at the conclusion that the year's working has resulted in a loss. Among the reasons for this are that the sum of £200 charged in respect of officers' salaries is inadequate, whilst the amount debited for public lighting is excessive. The auditor also reports upon the accounts for the year ended March 31st, 1907, but his remarks are not of such a condemnatory character. The gross profit is £6,191, compared with £10,550 8s. 4d. in the previous year. After debiting interest and sinking fund, there is a loss of £4,247 5s., after being charged against the accounts sums amounting to £1,489 17s., which the auditor states has been unjustifiably charged to capital in former years. The light railways accounts are also adversely criticised.

WEDNESBURY: *The New Electricity Works.*—At the request of the Board of Trade, a meeting was held a short time ago between representatives of the Midland Electric Corporation for Power Distribution and the Wednesbury Corporation with regard to the supply of electricity. At present the Corporation take a supply in bulk from the company, but has gone into details with the object of erecting a separate generating station. At the meeting at the Board of Trade offices, the terms upon which the Midland Company would continue to give the present supply were discussed, but the representatives of the Corporation were of the opinion that these new terms would not enable them to carry on their undertaking except at a loss. Since then the Corporation has received a notice from the company intimating their intention to terminate the present agreement for a supply in bulk on March 31st. As the Corporation's generating station has not yet been commenced, a letter disapproving of the company's action has been served upon the company. The peculiarity of the position is that the Midland Electric Corporation for Power Distribution has a Provisional Order for giving a general supply in Wednesbury, and has declared its intention of laying mains in order to give a direct supply, and not through the Corporation as at present. The Wednesbury Corporation has been seeking to obtain a revocation of the company's order at the hands of the Board of Trade on the ground that the price at which energy is now supplied entails a charge upon the rates at the end of each year's working.

WIGAN: *Infirmary Lighting.*—The Board of Guardians have before them estimates for an electrical installation and a supply of gas from the Gas Co. The former is being strongly opposed on the ground that the wages for looking after the plant would be about £500 per year, and after a long discussion, the matter has been referred to the Estate Committee.

WIMBLEDON: *Refuse Destructor Management.*—A subcommittee has been appointed to consider whether, in view of the fact that most of the machinery at the Sewage Disposal Works is now electrically driven, it is desirable to make any re-arrangement of the staff there, and whether the refuse destructors should be placed under the control of the Borough Surveyor or the Electrical Engineer, or under the joint control of both.

YORK: *Commercial Developments.*—A complete scheme for developing the electric supply department of the Corporation is now being put into force, and will include advertising, canvassing for consumers, maintenance of electric light installations, &c. Electrical installations will also be carried out on the hire purchase system, and where electricity is used for power purposes, an amount equal to 10 per cent. of the total consumption will be allowed at power rates for lighting purposes.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ACCRINGTON.—The Electricity Committee have decided to obtain tenders for the supply of a cooling tower for the new 2,000 kw. plant.

ASTON.—The Electric Supply Committee recommend the installation of a 2,000-kw. three-phase 6,600-volt turbo-generator, in order to meet the increasing demands upon the station. The approximate cost of the necessary works is put at £33,000, of which sanction has already been received to £7,787, leaving a balance of £25,213 still to be sanctioned. The scheme also includes the installation of two 400-kw. and one 300-kw. motor-generators.

AUSTRALIA.—The representative of the Commonwealth in London (Captain R. Muirhead Collins, C.M.G., notifies that he has received tender forms, specifications, &c., in connection with the supply and delivery of thirty-three switchboards for private branch exchanges for common battery working, for which tenders will be received at the office of the Deputy Postmaster-General, Sydney, up to 2.30 p.m. on March 4th. Specifications, tender forms, &c., may be obtained at the Commonwealth Offices in London, 72 Victoria Street, S.W., where also preliminary deposits on tenders may be paid. Copies of the specification and conditions may be inspected at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

Captain R. Muirhead Collins, C.M.G., has also received tender forms, specifications, &c., relating to the following :—Required by the Postmaster-General's Department at Melbourne :—(*a*) Apparatus for exchange : one common battery switchboard, of 30 sections in all, together with all associated frames, racks, power plant, and parts ; (*b*) apparatus for subscribers' premises : 3,000 telephone wall sets, 1,000 telephone table sets, 150 extension switches (complete), 70 switchboards for 2 and 6 lines, 50 switchboards for 3 and 10 lines, 10 switchboards for 6 and 20 lines, 10 switchboards for 8 and 50 lines, 200 telephone wall sets, and 100 telephone table sets for party lines. Tenders will be received at the Office of the Deputy Postmaster-General, Melbourne, until 3 p.m., on May 26th.

BARKING.—The Council invite tenders for the supply and delivery of electrical sundries, carbons, meters, &c. Full particulars from the Electrical Engineer's office, East Street, and tenders to the Town Clerk by February 25th.

BELFAST.—Tenders are invited by the Corporation for the supply of low-tension cable during the twelve months ending March 31st, 1909.

BLACKBURN.—The Electricity and Tramways Committee invite tenders for the supply of the following stores during the year ending March 25th, 1909 :—General stores (including paints, varnishes, &c.), iron brass castings, bolts, bars, &c. ; timber ; glass ; insulating material ; tools, brushes, &c. ; oils, &c. ; wrought-iron pipes ; house service fuse boxes, switches, &c. ; motors ; motor starting switches ; screwed tubes for inside wiring. Specification and forms of tender from the Borough Electrical Engineer, and tenders to the Chairman of the Electricity Committee by February 15th.

BRISTOL.—The Docks Committee invite tenders for the supply, delivery and erection, and maintenance for 12 months after they have been in use, of electric cables for the supply to Avonmouth Docks. The tenders are also to include the construction, delivery, erecting in place, fitting, completion, and testing and the maintenance for 12 months after they shall have been taken into use of the electric lighting installations, complete in all details, for the various buildings, railway yard, wharves, &c., at the Royal Edward Dock, now in course of construction at Avonmouth. Specifications, &c., from the Secretary of the Docks Committee (fee £5, returnable), and tenders to 19 Queen Square, Bristol, by February 17th.

BURNLEY.—Tenders are invited for the supply of a booster to the electric lighting station at Burnley Union Workhouse. Tenders should be sent in by February 12th.

The Tramways Committee recommend the purchase of five additional tramcars similar in design to those recently put into use on the Manchester-road service. The cost is estimated at £800 each. The bodies of the cars, together with motors and fittings, will be purchased separately, and the cars built at the local depôt.

The Town Council has adopted a recommendation to purchase a 750-kw. steam generator at a cost of £6,835, and a motor-driven centrifugal pump at the cost of £265.

BURY.—The Corporation has had laid before it the estimates of expenditure upon the proposed new electricity works. Land, buildings, sidings, and plant for an initial capacity of 2,000 kw. is estimated to cost £39,881 ; for a capacity of 3,000 kw., £48,155, and for a capacity of 4,000 kw., £55,720. The cost of connecting up the new works with the existing generating station is estimated at £6,300, whilst £10,000 is included for transformers and high-tension mains. Mr. S. J. Watson, the Borough Electrical Engineer, estimates the cost per kilowatt installed at £19·9, £16·05, and £13·9 respectively for the three capacities mentioned above. The committee, having considered the three schemes, has decided to recommend the Corporation to apply for borrowing powers to the extent of £72,000.

CASTLEREA.—The Rural District Council invite tenders for a suction gas plant, dynamos, battery switchgear, overhead distribution lines, arc lamps, and service connections for the electric lighting of the town of Ballaghaderreen. Plans may be inspected at the office of the Consulting Engineer, Mr. L. J. Lawless, 27 Castlewood-avenue, Rathmines, from whom specification, &c., may be obtained (fee £2, returnable). Tenders to the Clerk of the Council by February 22nd.

CLACTON.—The Electricity Committee recommend an expenditure of £4,000 upon additional generating plant.

COLNE.—A special report has been presented by the Electrical Engineer relating to the necessity for purchasing an additional feeder for supplying electricity to the centre of the town. It was resolved to apply to the Local Government Board for sanction to borrow £1,670 for high-tension cable, £1,000 for extension to mains, and £1,500 for the hiring out of motors.

Digitized by Google

CORNWALL.—The County Asylum Committee are considering the question of installing electricity or gas at the County Asylum.

EDINBURGH,—Tenders are invited for an extension switchboard panel. Specifications, &c. (fee, two guineas, returnable), from Sir Alex. B. W. Kennedy, the consulting engineer to the Corporation, 17 Victoria Street, London, S.W., and tenders to the Town Clerk by February 10th.

FINCHLEY.—The application of the District Council for sanction to borrow £22,000, for purposes of electric lighting—to which no opposition was offered—was the subject of a Local Government Board inquiry, conducted on January 30th by Mr. H. Ross Hooper, M.I.C.E. The estimate upon which the present application was based is as follows:—Buildings, £12,000; mains and meters. £10,000.

GRAVESEND.—Stores are required by the Electricity Department as follows:—Small coal, engine stores, oil stores, lamp stores, carbons, and meters. Specifications, &c., from the Borough Electrical Engineer, and tenders to the Town Clerk by February 17th.

GLASGOW.—The Tramways Department invite tenders for the supply and erection of two movable bridges over the Forth and Clyde Canal at Dalmuir and Kilbowie. Full particulars from the General Manager, 46 Bath Street, Glasgow, and tenders to the Town Clerk by April 13th.

HALIFAX.—The Tramways and Electricity Department invite tenders for lighting fittings, electrical accessories, oils and grease, paints and varnishes, tubes and fittings. Full particulars may be obtained from the General Manager, and tenders to the Town Clerk by February 12th.

HEYWOOD.—The Electricity and Tramways Committee recommend the expenditure of £8,000 upon extensions of the Electricity Works.

HORNSEY.—The Council invite tenders for the installation of electric light wiring and fittings in the following depôts:—Sanitary Depôt, Highgate; Central Fire Station, Hornsey; Branch Fire Station, Harringay; Branch Fire Station, Muswell Hill; Fire Box, Stroud Green; Fireman's Mess Room, Highgate; Firemen's Dwellings, Hornsey; Clock Tower, Crouch End. Particulars, &c., from the Borough Electrical Engineer (fee, 10s. 6d., returnable), and tenders to the Town Clerk by February 17th.

HULL.—The Education Committee of the Corporation invite tenders for an electric light installation and fans at the Selby Street West School, now in course of erection. Full particulars may be obtained from the City Architect, and tenders should be sent to the Town Clerk by February 10th.

ILFORD.—Tenders are invited for the supply and delivery of a 1,000-kw. steam generator, watertube boiler, &c. Particulars from the Council's Electrical Engineer, and tenders by February 28th. (See an advertisement this week.)

LEEDS.—Tenders are invited by the Electric Lighting Committee for steam, exhaust, overflow, and other pipes, valves, &c., in connection with a steam turbo-generator of 3,000 kw. capacity. Particulars from H. Dickinson, manager, the Whitehall Road, Leeds (fee, two guineas, returnable), and tenders to the Town Clerk by February 10th.

The Tramways Committee invite tenders for the supply of stores during the year ending March 31st, 1909, including electrical sundries.

Tenders are also invited for the supply of steam coal for the generating set for six, nine, or twelve months' supply. The consumption is approximately 500 tons per week; also for the supply of household coal and delivered at the various offices and depôts as required. Particulars may be obtained from the General Manager, at the Tramway Offices, City Square, Leeds, and tenders should be sent to the Town Clerk not later than February 21st.

LONDON: *Bermondsey.*—Tenders for the supply of the following stores during the year ending April 1st, 1909, are invited:—Arc lamp carbons and brushes, cable and jointing material, conduits, electricity meters, demand indicators, and main fuses, engine oils, meter boards, street frames and covers and joint boxes. Full particulars from the Electrical Engineer, and tenders to the Town Clerk by February 17th.

Battersea.—The Council invite tenders for the supply of stores as follows, for the year ending March 31st, 1909:—Oils, engine room stores, coal, carbons for arc lamps, electricity meters, service joint boxes, ironmongery, tools, &c. Particulars from the Electrical Engineer, Electric Light Station, Lombard Road, Battersea, and tenders to the Town Clerk by February 18th.

Hammersmith.—The following stores are required for the Electricity Department during the twelve months ending March 31st, 1909:—Arc lamp gloves, &c., brooms and brushes; electrical goods; files; fire bricks; clay and lime; gauge glasses; insulated wires; metals; meters; oilman's goods; packing and jointing materials; screws and tools. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by February 19th.

Islington.—The Borough Council invite tenders for the supply of the following stores during the year ending April 1st, 1909: Engine-room stores, &c., arc lamp carbons and globes, oil, transformers and accessories, &c.; electricity supply meters, prepayment meters, cables; electrical sundries: lamps, brushes, arc lamp parts, &c.; terminal service and network boxes. Particulars from the Town Clerk, to whom tenders by February 18th.

Tenders are also invited by February 25th for (*a*) one 1,500-kw. steam-turbine alternator, &c., (*b*) water-tube boiler, conveyor, &c.

LONG EATON.—A Local Government Board inquiry was held last week into an application by the Council to borrow £10,000 in connection with the electricity undertaking. There was slight opposition.

OLDHAM.—A Local Government Board inquiry was held last week into the application of the Corporation for sanction to morrow £1,500 for meters. There was no opposition.

PORTSMOUTH.—Tenders are invited for supplies from April 1st as follows:—Electrical goods, paints and sundries, printing, brooms, brush, &c., castings and ironmongery, street works (laying cables, &c.), also for carting coal from steamers to bunkers at the electric lighting station, Portsmouth. Particulars from the Electric Supply Works, and tenders to the Town Clerk by February 12th.

RATHMINES AND RATHGAR.—Tenders are invited for the supply of the following stores during the twelve months to March 31st, 1909:—Coal, arc lamp carbons, incandescent lamps. Tenders to the Town Clerk by February 15th.

SALFORD.—The Tramways Committee invite tenders for an additional electric light installation at the Central Depot in Frederick Road, Pendleton. Full particulars from the General Manager, 36 Blackfriars Road (fee £1 1s., returnable), and tenders to the Town Clerk by February 17th.

SHEFFIELD.—Tenders are invited for a supply of stores as follows for the twelve months ending March 25th, 1909:—Electrical supplies and fittings, cable, car fittings, car lamps, wood slipper blocks, steam tubes and fittings, overhead line material. Full particulars from the General Manager, Tramway Department, Division Street, Sheffield, to whom tenders by February 10th.

The Cleansing Department of the Corporation requires engineering and electrical fittings among other stores during the year ending March 25th, 1909. Tenders to the Superintendent, from whom full particulars may be obtained, by February 11th.

SOUTH SHIELDS.—A Local Government Board inquiry was held last week into the application by the Corporation for sanction to borrow £7,052 for the provision of additional plant at the electricity works. There was no opposition.

STOKE-ON-TRENT.—The Electrical Engineer having prepared estimates with regard to the probable future demand upon the electricity undertaking, the electricity committee recommend that application be made to the Local Government Board for sanction to borrow £5,965.

SWANSEA.—Tenders are invited for the supply and delivery of motors and starting switches during the ensuing year. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by February 21st.

WALTHAMSTOW.—An automatic signalling apparatus on the Hoe Street and Chingford Road tramway route is to be provided, subject to the Board of Trade giving their sanction to the cost being met out of capital.

WEST HAM.—Tenders are invited for the supply of engine-room stores, rubber-covered cable electric wiring materials and accessories, and chemicals. Particulars from the Borough Electrical Engineer's office, 84 Romford Road, Stratford, E. Tenders by February 6th.

WIMBLEDON.—The Corporation invite tenders for the supply and erection of the undermentioned plant at their electricity works, and are prepared to accept tenders subject to the sanction of the Local Government Board being obtained for the necessary loan:—(*a*) A 1,000 kw. turbo-alternator, with condensing plant; (*b*) two water-tube boilers, economisers, pipe-work, and feed pump; (*c*) high-tension main switchboard and switchboard gallery. Forms of specification and tender, with the general conditions, may be obtained from Mr. H. Tomlinson-Lee, the Borough Electrical Engineer, Electricity Works, Durnsford Road, Wimbledon (fee £1 each specification, returnable), and tenders to the Town Clerk by February 18th.

Having regard to the present favourable price of copper, tenders for the supply of cables and conduits for the financial year beginning March 31st, 1908, are to be invited at once.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The tender of Messrs. Swanson Bros., of Melbourne, for the erection of the Windsor Telephone Exchange at £7,374 has been accepted by the Postmaster-General's Department. The following tenders have been accepted by the Queensland Postmaster-General's Department:—Brisbane Electrical Company: 1,760 No. 2 carporous cells, at 2s. 3d. each; 20 coin attachments, at £1 4s. 6d. each; 9 battery pole-changers, at £3 13s. each; 50 B.S. telephones, at £3 10s. 6d. each. G. R. Hodson, Brisbane: 536 No. 2 Leclanche cells, at 1s. 1d. each; 48 Edison Lalande cells, type Q, at 7s. 4d. each; 288 copper oxide plates, at 1s. 1½d. each; 576 zinc plates for Lalande cells, at 6d. each. I. R. G P. and Telegraph Works Co., Sydney: 8 resistance coils, at £2 11s. each. James Paton & Co., Sydney: 60 visual vibrating indicators, at 8s. 3d. each; 4 operators' sets, at £2 2s. 9d. each. Lawrence & Hansen, Sydney: 880 B.S. wall telephones, at £2 17s. 6d. each.

BURY.—Subject to the sanction of the Local Government Board, the tender for the construction of the chimney at the proposed new electricity works has been given to Mr. C. Dennis, of Bury.

GLOUCESTER.—The following tenders for stores have been accepted by the Light Railways Committee:—L. Andrews & Co., micanite plate, red fibre sheet, asbestos sheet, Baker's fluid; Anglo-Russian Oil Co., light car oil paraffin; Anti-Attrition Metal Co., anti-friction metal; British Insulated & Helsby Cables, Ltd., cables; Brown Bayley Steel Works, Ltd., car wheel tyres; J. M. Butt & Co., brake blocks.

HULL.—Upon the recommendation of the Telephone Sub-committee, the tender of the British Insulated & Helsby Cables, Ltd., for the supply of cables at £254 3s. was accepted, and also the tender of Messrs. Macmillan & Co., for instruments at £368 15s.

LONDON: *Bermondsey.*—An order has been placed with Messrs. Grover & Sons for a pair of 7-ft. wheels for a cable drum at the electricity works, at £16 10s.

Shoreditch.—The following tenders have been received for the supply of lead-covered, paper-insulated cable service cables:—W. T. Henley's Telegraph Works Co., Ltd. (accepted), £298 1s. 5d.; Western Electric Co., £302 11s.; W. T. Glover & Co., Ltd., £302 15s.; British Insulated, &c., Cables, Ltd., £304; Callenders' Cable and Construction Co., Ltd., £305 15s. 6d.; Siemens Bros. & Co., Ltd., £306 13s.; Lahmeyer Electrical Co., Ltd., £321 13s. 9d.; Geiple & Lange. £338 10s 8d.

LEYTON.—The Council has confirmed the recommendation of the Electricity Committee that the tender of Messrs. Carter and Wright for the supply of a lathe, and of that of Messrs. Tangyes, Ltd., for the supply of a screwing machine, and Messrs. Carter and Wright, emery grinder, at £14.

METROPOLITAN ASYLUMS BOARD.—The tender at £30 of Messrs. Buchanan & Curwen for the supply of new main cables has been accepted.

"ORIFLAMME" LAMP CONTRACTS.—The following orders have been received by Oliver Arc Lamp, Ltd., for the "Oriflamme" lamp:—From the Admiralty for H.M. Dockyard, Devonport (Keyham Extension); Haulbowline Dockyard; London & North-Western Railway, for Crewe (37 lamps); and from the Portsmouth Corporation, extension order for 25 lamps for street lighting.

ROCHDALE.—Subject to the Corporation accepting the recommendation of the Electricity Committee, the contract for a steam dynamo has been placed with the General Electric Co. (Browett, Lindley & Co.'s engine), and the contract for coal with Messrs. Simeon Wood, of Rochdale.

VLADIVOSTOK.—It is announced that the contract for the erection of an electric lighting installation and also for the construction of tramways in Vladivostok has been given to a German firm at £158,000. The work is to be completed by July, 1909.

WIMBLEDON.—Two transformers, one of 25 kw. capacity and the other of 35 kw., belonging to the Corporation, being reported useless, the Electrical Engineer has been authorised to obtain a new 75 kw. transformer in exchange, plus payment of £58.

COMPANIES' MEETINGS AND REPORTS

BLACKPOOL & FLEETWOOD TRAMROAD.—The report for the half-year ending December 31st, 1907, states that, including the sum brought forward from last half-year, the balance of profit, after providing for debenture interest, is £12,537 16s. 11d., and the directors recommend a dividend at the rate of 9 per cent. per annum, which will absorb £6,750, writing off a sum of £2,500 to depreciation reserve, and £878 18s. to general reserve account, leaving a balance of £2,408 18s. 11d. to be carried forward to the current half-year. The number of passengers carried during the half-year was 1,799,442. The receipts from all sources amounted to £23,869 17s. 5d.

CITY & SOUTH LONDON RAILWAY.—The report of the directors for the half-year ending December 31st, 1907, shows that the receipts from all sources have amounted to £89,149 14s. 8d. and the cost of working has been £41,387 3s. 7d., leaving a profit of £47,762 11s. 1d. Inclusive of the balance brought forward from June 30th last, the net revenue account shows an aggregate total of £49,619 16s. 1d. After making provision for the debenture stock interest, rent charge, and the transfer to the renewal fund of £1,500, a balance remains available for dividend of £34,069 12s. 3d. Out of this sum the directors recommend that the full dividend of 5 per cent. per annum be paid on the preference stocks, 1891, 1896, 1901, and 1903, and that a dividend at the rate of 1¾ per cent. per annum be paid upon the consolidated ordinary stock for the half-year, leaving a balance of £1,119 12s. 3d. to be carried forward to the next account. The number of passengers, exclusive of season ticket holders, during the half-year under review was 10,732,145, compared with 9,104,295 during the corresponding period of 1906. The dividend paid for the June half-year of 1907 was 2½ per cent., and 2 per cent. for the December half-year of 1906. The reduction of dividend in the present accounts is attributed to the abnormally high cost of coal and general stores, and also to the competition with the electric tramways in the north of London. Concerted arrangements have been entered into with all the Tube Railways and the Metropolitan and District Companies for exhibiting a combined large map, and for the gratuitous distribution of small folder maps, as well as for advertising generally. By this means it is hoped to educate travellers to make more use of the intercommunication between the various underground systems. Through bookings, of a kind likely to be of great convenience to the public, have been arranged between this company's line and the suburban stations on the Great Northern and Midland Railways, also with the Metropolitan Railway and the Central London, Hampstead (and Highgate) and Piccadilly Tubes. These are in addition to the previously arranged through bookings with the Brighton Railway and the Baker Street and Waterloo and Great Northern and City Tubes. Two additional new steel five-coach trains have just been delivered by the Brush Electrical Engineering Company. One of these has been put into the traffic, and the other will follow in a few days. The additional engine required at the generating station for the Euston extension has been erected, and is at work. The train mileage run during the December half-year of 1907 was 683,950, compared with 652,048 in the corresponding period of 1906. The rolling stock now consists of 52 locomotives and 155 carriages. The meeting will be held on Tuesday, February 11th.

GIANT'S CAUSEWAY & PORTRUSH ELECTRIC TRAMWAY.—The directors report a decrease in the receipts during the year 1907 of £385, and a decrease in the passengers carried of 15,000. This unfavourable result is mainly attributed to the unfavourable weather, the International Exhibition in Dublin, and the prolonged strike in Belfast, which prevented many excursions being made.

GREAT NORTHERN AND CITY RAILWAY.—The report for the half-year ending December 31st, 1907, shows total revenue receipts of £47,582 6s. 6d., and working expenses of £24,778 4s. 8d., the percentage of expenses to receipts being 52·07 per cent. Inclusive of the balance brought forward from June 30th last, and after providing for interest on debenture stock and other charges, and setting aside £500 to renewal fund, there remains a balance of £379 10s. 8d., which the directors recommend to be carried forward to next account. The number of passengers carried during the six months under review, including season ticket-holders, was 7,543,174, as against 7,901,923 for the corresponding period last year. The number of local season tickets issued during the half-year was 3,703, as against 3,013 for the half-year ending December 31st, 1906. The directors, after careful consideration, and in conjunction with the Great Northern Railway, decided upon a revision of fares which involved certain increases. This new arrangement came into operation on November 1st, 1907. The effect has been, to a large extent, to check the decline in revenue arising from the severe competition which the company has had to contend during the past half-year. The train mileage run during the half-year was 367,339, and the car mileage 1,109,179. The meeting is to be held to-day.

LANARKSHIRE TRAMWAYS.—An exraordinary general meeting was held last week at 83 Cannon Street to confirm the promotion of a Provisional Order under the Private Legislation.

LIVERPOOL OVERHEAD RAILWAY.—The report of the directors for the half-year ended December 31st, 1907, shows

Digitized by Google

that the gross revenue receipts amounted to £41,136 2s. 6d., and the working expenses to £32,154 7s. 2d. The number of passengers carried were 5,864,629, compared with 5,425,595 in the June half-year, and 5,555,555 in the December half-year of 1907. The revenue account shows that the receipts from passenger traffic amount to £40.135 19s. 6d.; miscellaneous receipts and interest, £1,000 3s.; a total of £41,136 2s. 6d. Deducting working expenses, transfer to renewal fund, and interest on mortgage debentures, and on calls paid in advance, leaves £4,652 7s. 2d., to which is added the balance brought forward, June 30th, 1907, viz., £4,452 8s. 1d., leaving available for dividend, £9,104 15s. 3d. The increase in the working expenses is mainly owing to additional cost of coal and stores. The directors recommend the declaration of dividends at the following rates (less income tax):—5 per cent. dividends at the following rates (less income tax):—5 per cent. per annum on preference shares, £3,675 17s.; ½ per cent. per annum on ordinary shares, £1,250; leaving a balance of £4,178 18s. 3d. to be carried forward to next half-year. The meeting will be held on Tuesday.

METROPOLITAN RAILWAY.—At the half-yearly general meeting on Wednesday last week the report and accounts given in our last issue were adopted. Sir C. McLaren, Bart., M.P., who presided, said that there had been a decrease in the ordinary passengers carried over the previous year of 1,131,040. This was attributed to the multiplication of tube railways in London having only one class of car, and which discouraged the habit of paying a higher fare on such lines as the Metropolitan, where more than one class of accommodation was given. Another factor in the decrease was that it had been necessary to increase slightly the number of their fares, which experience had shown to be too low. The increase in the third-class fares, however, had helped the receipts materially, but the company still felt very seriously the effect of the new competition from the Piccadilly and Brompton Railway, the City and South London Railway, and also the London County Council Tramways. Whilst, however, these new means of communication had diverted a considerable amount of traffic, yet, on the other hand, they were beginning to bring traffic in their capacity as feeders to the Metropolitan Railway, and the directors had confidence that in time this new source of revenue would balance the loss in the other direction. With regard to the expenditure, the maintenance of permanent way, works, and stations showed a decrease of £1,982, but mainly owing to the greater train mileage run and to the high price of coal, the locomotive and generating expenses had increased by £4,754. Fortunately, they had arranged their contracts for most of their power-house coal before the rise took place. Rates and taxes showed a decrease of £4,513, due to money returned upon the adjustment of their assessments. The balance of account for working trains for other companies showed an increased credit of £4,427, a portion of which was due to the arrangement with the District Company to provide the whole of the Inner Circle train service. In this way the percentage of expenses to receipts had been reduced from 62·19 per cent. to 59·76. The result was that the amount taken to net revenue account had increased by £9,690, and the balance available for dividend was £124,357. With regard to the London Traffic Conference, he thought there was every reason to be satisfied with the progress made up to date. In conclusion the chairman stated that the view of the Board was that the prospects of the company at the present time were much brighter than they had been for several years.

NOTTING HILL ELECTRIC LIGHTING.—An extraordinary general meeting was held on Monday to pass a resolution confirming the Bill introduced into Parliament by the Notting Hill Electric Lighting Co. in conjunction with the Kensington & Knightsbridge Electric Supply Co., St. James and Pall Mall Electric Supply Co., The Westminster Electric Supply Corporation, and Central Electric Supply Co., having for its object the removal of certain restrictions imposed upon the companies by their present Provisional Orders. Sir William Crookes, who presided, stated that the Bill gave the companies power to associate for the purpose of bulk supply, to lay down the necessary mains for the purpose of this bulk supply, and to provide that the mains so laid should not be liable to purchase by the local authority. The Bill also revises the charges imposed by Provisional Orders. Referring to the Bill promoted by some other of the London companies for the purpose of giving a bulk supply in London, the Chairman said that the companies concerned in the Bill before the meeting thought it advisable to oppose the abovementioned Bill, and also that promoted by the London & District Electric Supply Co., in order to get certain clauses amended. The resolution before the meeting was approved.

Obituary.—The death took place at Belfast of Mr. John Woodside, a well-known Irish electrical engineer, on the evening of the 2nd inst. He carried out many important installations, including those of the Belfast and Sheffield Hippodromes, Purdysburn Asylum, and numerous mills and factories in the north of Ireland, and at the time of his death he had the lighting of Portrush and the Abbey Sanatorium, Whiteabbey, in hand. He was in his thirty-seventh year.

NEW COMPANIES

BRITISH PHOTO-LEXIGRAPH CO.—This company was registered on January 28th with a capital of £12,500 in £1 shares to work, exploit, hire, or acquire an electrical advertising apparatus known as the "Photo-Lexigraph," and patents Nos. 5,996 of 1905, and 13,284 of 1906 in respect thereof to adopt an agreement with C. J. Marrian and H. E. Wells, and to carry on the business of general advertising agents and contractors, electricians, electrical and mechanical engineers, manufacturers of and dealers in electrical, magnetic, and other appliances, &c. The subscribers are:—T. W. O. Wheeler, J. Hewett, H. E. Wells, C. J. Marrian, F. W. Marrian, R. D. Walrond, and F. A. Walton. No initial public issue. The number of directors is not to be less than two, nor more than five; the subscribers are to appoint the first. Qualification, £100. Remuneration, £150 each per annum. Registered office, 3 Mincing Lane, E.C.

CONTRACT AND FINANCE SYNDICATE.—This company was registered on January 29th with a capital of £1,000 in £1 shares to acquire mines, to explore and prospect land supposed to contain minerals or precious stones in Spain or elsewhere, to construct and maintain railways, tramways, or aerial cable ways operated by electric or other power, to carry on business as financiers, contractors, and carriers, &c. The subscribers are:—C. N. Jelly, Elizabeth M. Rogers, F. A. Wilmot, J. R. Thorn, H. S. Pilch, O. H. Snazelle, and H. G. Gorringe. No initial public issue. The number of directors is not to be less than two, nor more than five. The subscribers are to appoint the first. Qualification (except first directors), 150 shares. Remuneration (except managing director), £50 each per annum (chairman, £75), and 5 per cent. of the surplus profits remaining after 10 per cent. has been paid on the shares, dividend (maximum in any year, £2,500). F. A. Wilmot is secretary.

HESWALL DISTRICT POWER CO.—This company was registered on January 28th with a capital of £30,000 in £1 shares to adopt an agreement with H. W. Robinson and R. Carter, and to carry on at Heswall, Cheshire, or elsewhere the business of an electric supply company. The subscribers are:—R. Carter, C. A. Robinson, T. L. Miller, H. W. Robinson, E. B. Driffield, F. T. P. Deyes, W. H. Pollitt. Minimum cash subscription, 25 per cent. of the shares offered to the public. The number of directors is not to be less than three, nor more than seven; the subscribers are to appoint the first. Qualification, £100. Remuneration as fixed by the company.

MERCEDES ELECTRIC MANUFACTURING CO.—This company was registered on January 25th with a capital of £50,000 in £1 shares to carry on the business of manufacturers of motors, motor-cars, cycles, and other vehicles of all kinds, whether driven by electrical or other power, &c., and to adopt an agreement with Mercedes Mixte, Ltd. The subscribers are:—F. H. March, G. W. Eastham, J. Irwin, V. Jackson, W. S. King, T. R. Wells, J. E. Murray. No initial public issue. The number of directors is not to be less than two, nor more than eight; the subscribers are to appoint the first. Qualification, £100. Remuneration as fixed by the company. Registered office, 11A Regent Street, S.W.

PEEBLES & CO.—This company was registered in Edinburgh on January 27th with a capital of £15,000 in £1 shares to purchase and carry on the business of gas-meter, gas governor, and gas apparatus manufacturers, carried on by Bruce Peebles & Co., at Tay Works, Bonnington, Edinburgh. Power is also taken to carry on the business of engineers, electricians, brass and iron-founders, tube makers, metal workers, wire drawers, &c. The subscribers are:—W. H. Tilley, F. C. Tilley, W. C. Peebles, J. Peebles, A. Blyth, B. Sutherland, and G. K. Grieve. The number of directors is not to be less than two, nor more than five; the first are W. C. Peebles, W. H. Tilley, and F. C. Tilley. Remuneration, £50 each per annum. Registered office, Tay Works, Bonnington, Edinburgh.

SCRIVEN HERMANOS Y COMPANIA.—This company was registered on January 29th with a capital of £5,000 in £1 shares to equip, work, and maintain a railway or railways in Spain, to acquire any rights, benefits, and privileges which may be conferred by the Spanish Government or other authority, to construct, equip, or acquire, work and maintain tramways or aerial cable-ways, operated by electric or other power, telegraph and telephone lines, &c. No initial public issue. The subscribers and other particulars are the same as in Contract & Finance Syndicate, Ltd.

S.P. (SUCHOSTAWER PATENTS) SYNDICATE.—This company was registered on January 27th with a capital of £6,500 in £1 shares to adopt an agreement with D. Suchostawer and S. A. Lehmann, and to carry on the business of iron and brass-founders, mechanical engineers, tool makers, metal workers, electrical, railway, tramway, and water-supply engineers, manufacturers of rolling stock and electric, steam, water, gas, air, and other engines, pumps, and machinery, &c. Minimum cash subscription, £300. The number of directors is not to be less than two, nor more than five; the subscribers are to appoint the first. Qualification, £10 shares or stock. Remuneration, £50 each per annum (£75 for the chairman). Registered office, 88 Fenchurch Street, E.C.

Digitized by Google

"Z" ELECTRIC LAMP MANUFACTURING CO.—This company was registered on January 25th with a capital of £150,000 in £1 shares to acquire the business of the "Z" Electric Lamp Syndicate, Ltd., and that of the Albion Electric Lamp Works, which the said syndicate has contracted to purchase, to adopt an agreement with the said syndicate, W. L. Pakenham (as trustee for the holders of the "A" shares therein) and H. F. Brown (as trustee for the holders of the "B" shares therein), and to carry on the business of manufacturers of incandescent lamps and the component parts thereof, makers of and dealers in electrical apparatus, fittings, and plant, &c. The subscribers are:—W. B. M. Bird, H. E. Andrews, H. M. Stevenson, H. F. Brown, A. P. Simpson, and E. P. S. Freed. No initial public issue. The number of directors is not to be less than three, nor more than seven; the first are J. G. B. Stone, chairman (9 Drapers Gardens, E.C.), F. R. Reeves (Salisbury House, E.C.), A. R. Norbert (12 Rue Pelouze, Paris), H. Stevenson, and W. B. M. Bird. Qualification, £500 shares or stock. Remuneration, £100 each per annum (£150 for the chairman). Directors' borrowing powers restricted to £75,000. Registered office, Orient House, New Broad Street, E.C.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £63 to £63 10s. per ton (last week £64 to £64 10s. per ton).

CANNON STREET ARC LIGHTING.—We are informed that all the arc lamps in Cannon Street for the experimental City lighting are now of the "Oriflamme" type.

E.C.C. STAFF DINNER.—The annual dinner of the staff of the Electric Construction Co. took place at the Star and Garter Hotel, Wolverhampton, on Saturday last week. The chair was taken by Mr. W. Bullock, the manager, who was supported by Mr. W. Buchanan.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—In the liquidation of Messrs. Johnstone, Benjamin & Co., electric cable makers, a committee of inspection has been appointed to act with the Official Receiver and liquidator.

Creditors of the "Z" Electric Lamp Syndicate, Ltd., are requested to send in particulars of their claims to Mr. H. J. Owens, Orient House, New Broad Street, the liquidator, by March 2nd.

A general meeting of Wolfram, Ltd., will be held at the office of the company, 8 Laurence Pountney Hill, Cannon Street, London, E.C., on March 2nd, at 4.15 p.m., for the purpose of hearing the liquidator's account of the winding-up.

At an extraordinary general meeting of the "Z" Electric Lamp Syndicate, Ltd., on January 7th, resolutions were passed confirming the agreements made, whereby a new company has been registered, as notified above.

MESSRS. BROWN, BOVERI & CO.—We are informed that this firm's Italian house, "The Tecnomasio Italiano Brown Boveri," has lately amalgamated with Messrs. Gadda & Co., who were formerly their most important Italian competitors. In the future Messrs. Gadda will not themselves manufacture electrical machinery, but will confine themselves to contracting for electrical plants and managing the same. Moreover, Messrs. Gadda have bound themselves to buy from the Tecnomasio Italiano Brown Boveri all the electrical material they—or their sub-contractors—may require. The Tecnomasio Italiano Brown Boveri will take over Messrs. Gadda's works at the Via Castiglia, Milan, which employ about 1,000 workmen, and are equipped with the most modern tools and machinery. The old works of the Tecnomasio Italiano Brown Boveri in the Via Pace will be shut down and handed to Messrs. Gadda for sale. The erection of the new works of the Tecnomasio at the Porta Romana, which were started some time ago, will now be held back till required. After completion of these new works, which will allow of a considerably increased output, the Tecnomasio intend to abandon the Via Castiglia works and to remove entirely to the Porta Romana. The capital of the Tecnomasio Italiano Brown Boveri will be increased shortly to six million lire (£240,000). The Baden house intends to subscribe such a proportion of this increase as will enable the A. G. Brown, Boveri & Co. to hold half the whole capital. Both the technical and commercial management of the Technomasio Italiano Brown Boveri will remain in their hands.

Franco-British Exhibition.—The Town Clerk of Fulham has sent a circular-letter to the various Metropolitan Borough Councils, inquiring whether they favour the suggestion that the London local authorities owning electricity undertakings should co-operate with the London electric supply companies in arranging for a collective exhibition or demonstration of electricity at the Franco-British Exhibition.

MISCELLANEOUS CITY NOTES

AMERICAN WESTINGHOUSE CO.—The committee of creditors of the Westinghouse Electric & Manufacturing Co. has completed their plans for the readjustment of the company's financial position. From a statement prepared, it appears that there is a total unsecured debt to be provided for of about £7,000,000, and it is proposed to create an issue of first mortgage and collateral trust 5 per cent. 25-year gold bonds to this amount secured upon the principal manufacturing plant of the company.

BRUSH ELECTRICAL ENGINEERING CO.—It is proposed to consolidate the two present issues of 4½ per cent. debenture stock of £125,000 each, and at the same time to increase the amount by £100,000.

CARIBBEAN ANGLO-COLOMBIAN CABLE CO.—The *Financial News* states that the prospectus is in circulation of this company, which will have a capital of £200,000, divided into ordinary shares of £1 each; £110,000 six per cent. first mortgage debenture stock, and £50,000 six per cent. second mortgage debenture stock. The prospectus states that the company has acquired the exclusive privilege granted by the Government of the Republic of Colombia for a period of fifty years for laying and working submarine cables, or any other means of telegraphic communication between the Atlantic coast of Colombia, and any points situated outside the jurisdiction already supplied with telegraphic service. Under this concession the India Rubber, Gutta Percha & Telegraph Works Co., Ltd., will at once lay a cable between Puerto Colombia (Savanilla), and Kingston (Jamaica). At this latter point a connection will be made with the lines of the Direct West India Cable Co., with whom working arrangements have been made. The Colombian Government has guaranteed a half-yearly income of £14,384, and the India Rubber, Gutta Percha & Telegraph Works Co., Ltd., will provide the amount necessary to make the first two payments in respect of interest on the first and second debentures and the sinking fund for a reduction thereof.

CITY OF BUENOS AIRES TRAMWAYS CO. (1904).—A balance of 1s. 3d. per share for the year ended December 31st, 1907, is recommended, transferring £3,600 to the General Amortisation Fund, and carrying forward £144.

METROPOLITAN DISTRICT RAILWAY CO.—A dividend at the rate of 1¾ per cent. per annum is announced on the 4 per cent. guaranteed stock for the half-year ended December 31st, 1907. This compares with 1½ per cent. last year.

MONTREAL STREET RAILWAY CO.—Applications have been invited during the week for subscriptions at 96 for £460,000 4½ per cent. sterling debentures redeemable on May 1st, 1922.

NATIONAL TELEPHONE CO.—Subject to final audit, the directors recommend the following dividends for the half-year ended December 31st, 1907, after payment of dividends on the preference shares:—6 per cent. per annum on the preferred stock, and 6 per cent. per annum on the deferred stock, less income tax. The sum of £145,000 is carried to reserve, and about £10,000 is carried forward.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—A dividend of 10 per cent. per annum, less tax, for the half-year ended December 31st, 1907, is recommended. Last year the dividend was 13 per cent.

Telegraph Traffic.—Traffic may now again be accepted for India and the Far East, *viâ* Eastern, their Egyptian land lines having been restored on January 29th. At the same time their Perim-Djibouti cable broke, and was repaired on the following day. A notice of interruption was issued on the 1st instant of the Thorshavn-Seydisfjord cable, but was cancelled on the same day, it having been issued in error. Communication failed between Rome and Constantinople on the 3rd instant, and was put into working order again on the same day. Since the 4th instant the cable between Alexandria and Larnaca has ceased carrying traffic. The Russian Government now again accept telegrams in code and cypher without restriction, but when demanded the sender must produce and exhibit his code. The cable between Teneriffe and Senegal having been repaired, traffic can be sent *viâ* Teneriffe-Noronha. The Agricultural Conference at Barbados, one of the British West India Islands, has passed a resolution favouring the extension of the existing cable system at Bermuda to Barbados, Trinidad, and Demerara. As mentioned in a note elsewhere, the island of Trinidad has passed a similar motion in their Assembly. Reductions of rates would follow the laying of these cables. The Marconi Co. have announced their willingness to accept ordinary wireless telegraph messages at the rate of 7½d. per word; but they can only be accepted for Montreal, and must be handed in at the offices of the company, Watergate House, Adelphi.

Proposed Reorganisation of Tramways Round Paris.—A Reuter telegram states that at a discussion of the Conseil-Général of the Seine on the subject of the reorganisation of the tramways of the department, several speakers remarked that in England systems of traction by surface contact seemed to have given good results. It was eventually resolved that no change of system could be made except after special deliberation by the Council.

PARLIAMENTARY INTELLIGENCE

GREAT EASTERN RAILWAY (GENERAL POWERS) BILL.—The Leyton Urban District Council has agreed to request the Members of Parliament for that division to oppose this Bill upon the general principle involved in Clause 19, given in our issue for January 9, page 58, which empowers the company to supply electrical energy. The Council is also petitioning against the Bill in the ordinary course.

LONDON COUNTY COUNCIL (TRAMWAYS AND IMPROVEMENTS) BILL.—The Greenwich Borough Council has several matters in dispute with the London County Council in connection with their Tramways Bill, but the question of petitioning against it has been postponed, pending a conference to discuss the points of difference.

LONDON ELECTRIC POWER BILLS.—The Greenwich Borough Council has decided to petition against the London Electric Supply Bill and the London and District Electric Power Bill. The Leyton Urban District Council has also been advised by its legal Parliamentary Committee to oppose these two Bills mainly with a view to securing clauses to protect the streets, sewers, tramways, and electric mains.

The Thames Conservancy has resolved that a clause saving the rights of the Conservators should be introduced in the London Electric Supply Bill, which empowers the joint committee to be established to lay mains within certain riverside districts. In regard to the London and District Electricity Supply Bill, the Board has agreed that clauses and amendments for the protection of the Conservators' interests should be inserted in the Bill, including provisions that none of the works at Barking (the Bill authorises the acquirement of easements across or under a part of Barking Creek, for the purpose of laying electric mains or other works) shall be at a higher level than 30 ft. below Trinity high-water mark, and that dredging shall not be carried out except with the license of the Conservators. The Board also expressed the opinion that the clause allowing the company to abstract up to 200 million gallons of water per day from the river for condensing or other purposes should be amended so as to provide that the quantity of water to be taken in any one day shall not exceed 50 million gallons. Petitions will be presented should the promoters not undertake to insert the amendments required.

The Southwark and Shoreditch Borough Councils will also lodge petitions against the Bills.

Coupling Rods on Electric Cars.—Some tests have been made in America to determine what advantage is gained by coupling the wheels of motor bogies on electric cars. According to information given in the *Engineering Review*, an equipment with four motors showed a saving in energy consumption of about 30 per cent. when the wheels of the bogies were coupled together. One motor was then removed from each bogie, and the car tested against another car with a similar two-motor equipment, but without coupling rods; a saving of 15·5 per cent. was shown in the former case.

Iron and Steel Institute.—The annual general meeting will be held at the Institution of Civil Engineers, Great George Street, on Thursday and Friday, May 14th and 15th. The annual dinner will be held, under the presidency of Sir Hugh Bell, in the grand hall of the Hotel Cecil, on Thursday, May 14th. The Council will shortly proceed to award Carnegie research scholarships, and candidates must apply before February 29th. The awards will be announced at the general meeting. In order to be included in the voting list at the general meeting, applications from candidates for membership of the institute must be received at the office of the institute not later than Tuesday, March 24th.

Creosoted Wood for Tramway Tracks.—Mr. Justice Phillimore and Mr. Justice Walton, sitting as a Divisional Court in the King's Bench Division of the High Court on Monday and Tuesday, had before them the case of West *v.* The Bristol Tramways Co., on the appeal of the defendants from the decision of Judge Castle at Tolzey Court. Plaintiff, who is a market gardener at Bristol, complained that by reason of the defendant company having paved the roadway opposite his garden with wood blocks, treated with creosite, his plants had been injured, and consequently he brought an action, alleging that there was a nuisance. The case came before the Recorder of Bristol and a special jury. At the first hearing the jury disagreed, and on the second occasion judgment was entered on their findings for the plaintiff. An appeal was now brought by the defendant company, who pleaded that they were protected in what they had done by their statute, and submitted that on this ground, and also on the findings of the jury, that judgment should have been given in their favour. On Tuesday Mr. Justice Phillimore gave judgment. He said that in his opinion the appeal must be dismissed. No doubt the tramway company was ordered to keep in repair a portion of the highway, and to do it by using wood-paving, but the Act did not state that they were to use wood blocks treated with creosite. The plaintiff was therefore entitled to recover in respect of any damage he had suffered in consequence. Mr. Justice Walton agreed, and the appeal was dismissed with costs. Their lordships gave further leave to appeal.

APPOINTMENTS AND PERSONAL NOTES

The salary of the manager of the Leyton tramways (Mr. F. Schofield) is to be increased from £300 per annum by £25, from the 1st proximo, with annual increments of £25 to a maximum of £400. The salary of Mr. J. Cornell, head clerk of the tramways depôt, is to be increased from £130 by £10 from the 1st proximo, with annual increments of £10, to a maximum of £180.

The manager of the Hull Corporation Telephone Department, Mr. T. Holme, has made an application for an increase in salary, but the matter has been deferred for further consideration.

In consequence of the promotion of Mr. W. E. Ireland to rolling stock superintendent of the London County Council Tramways, the Highways Committee of the Council recommend the appointment as assistant rolling stock superintendent, at a salary of £250 per annum, of Mr. H. S. May, at present engineer and rolling stock superintendent in the tramways department of the Blackpool Corporation.

Mr. John Carnegie, assistant superintendent to the Edinburgh Telegraph Department, has just retired at the age limit. Mr. Carnegie joined the service of the Electric Telegraph Co. in 1865, and was subsequently transferred to the Post Office. He has been presented with a marble timepiece by the staff.

The Marconi Companies in America.—The *Electrical World* (New York) gives the following extracts from a memorandum of objections to the Berlin Convention submitted by the Marconi Wireless Telegraph Co. to the Senate Committee on Foreign Relations:—"The convention makes it obligatory upon private enterprises like the Marconi Co. to exchange wireless telegrams with all other ships and stations without distinction of wireless telegraph systems adopted by such ships or stations, and without regard to whether any business or commercial arrangement of interchange of traffic has been made or not. The arrangement thus proposed represents an enforced partnership to which the Marconi companies contribute everything and the German manufacturers of wireless apparatus nothing, neither invention nor capital, nor skilful enterprise. In short, the German company proposes to obtain artificially, through international legislation, the advantage of the position obtained by the Marconi companies in open competition and by private effort at private expense." The company also complain that the establishment of standard wave-lengths of 300 and 600 metres would render certain of their stations useless. It is also announced that plans are under consideration by the company for the opening of a new transatlantic station in the near future. As yet no definite steps have been taken in the matter, but it is stated that the intention is to build the new station at some point along the coast or in the vicinity of New York City.

TENDERS INVITED.

ILFORD URBAN DISTRICT COUNCIL,

ELECTRICITY DEPARTMENT.

THE ILFORD URBAN DISTRICT COUNCIL invite tenders for the Supply and Erection of the following plant, and are prepared to accept tenders subject to the Local Government Board's sanction being obtained for the necessary Loan:—

CONTRACT A 4.—One 1,000 Kilowatt Steam Dynamo comprising Vertical Engine coupled direct to Multipolar Dynamo.

CONTRACT A 5.—One Water-tube Boiler and Accessories.

Copies of the Specifications, including General Conditions, Forms of Tender, &c., may be obtained on and after Monday, 10th February, 1908, on depositing a cheque for One Guinea for each Contract with the undersigned, which sum will be refunded to *bona fide* Tenderers after the Tenders have been adjudicated on.

Extra copies of the Specification may be obtained by *bona fide* Tenderers at a charge of Ten Shillings per copy, which sum will not be refunded.

Any further information may be obtained at the offices of Mr. Arthur H. Shaw, M.I.E.E., A.M.I.Mech.E., Electrical Engineer to the Council, at the Electricity Works, Ley Street, Ilford.

Tenders sealed and marked "Tenders for Contract No. A——, Electricity Works," to be addressed to the "Chairman of the Urban District Council, Town Hall, Ilford," and to be delivered on or before 12 o'clock noon, on Tuesday, the 25th February, 1908.

The Council do not bind themselves to accept the lowest or any Tender.

JOHN W. BENTON,
Clerk to the Council

Town Hall, Ilford,
4th February, 1908.

SUMMARY

The annual Parliamentary return relating to tramways and light railways under municipal and under company control, contains detailed figures showing the growth of the tramway industry through the successive periods of horse, steam, and electric traction. (Page 225.)

The Postmaster-General received a deputation on Tuesday with regard to the new telephone charges, and in reply to the objections raised, pointed out the inequitable nature of the flat-rate systems, which he hopes will soon be totally abolished. (Page 226.)

A Parliamentary return of the amount of energy delivered during the past year in the Metropolitan Police district, and the average prices per unit obtained for power and heating, private lighting, and public lighting, has been issued. The total amount of energy delivered in the whole district was some 213 million units, and the average price obtained 2·839 pence per unit. Of the local authorities, West Ham, with the largest annual output of 8 million units, charges the lowest for energy for all purposes, the average price being 1·48 pence per unit. The lowest charge for private lighting was that of Fulham, where 1·1 million units were sold at an average price of 2·1 pence per unit. Of the supply companies, the lowest average charge for all purposes was that of the North Metropolitan Electrical Power Supply Co., in which case the average price was 1·39 pence per unit. (Page 226.)

The report of the District Railway Co. states that the gross receipts for the half-year to December 31st amounted to £224,463, an increase of £8,617 on the receipts for the corresponding half-year of 1906. The working expenses amount to £156,069, an increase of £350. There is a deficit of £34,391, after providing loan charges and interest on debenture stock, added to which is the sum of £10,937 dividends on 4 per cent. guaranteed stock. The accounts of the Baker Street & Waterloo Railway for the December half-year shows a credit balance of £17,670. The gross receipts of the Charing Cross, Euston & Hampstead Railway Co. amounted to £74,328, and the expenditure to £61,354. After providing for interest and loans, the accounts of the Great Northern, Piccadilly & Brompton Railway Co. show a credit balance of £7,114. (Page 227.)

A good deal of interest was shown in Mr. J. S. Peck's Paper on protective devices for high-tension circuits, discussed last Thursday at the London meeting of the Institution of Electrical Engineers. The Paper itself, which dealt generally with the nature of voltage surgings in transmission systems, and described several

Digitized by Google

forms of lightning arrester, was given in a slightly abbreviated form in our last issue. Prof. G. KAPP described a method of making the action of the horn arrester more reliable, and dealt with a proposed system of cable charging with the object of preventing voltage surgings, and several speakers related experiences pointing to the unsatisfactory nature of some forms of protective apparatus hitherto available for overhead lines. Some remarks were made by Mr. PATCHELL and Mr. BRAZIL on the ultimate success of the methods adopted for the protection of the cables of the Charing Cross Co.'s system after a good deal of experiment. Mr. PECK briefly replied, but was prevented from business reasons from giving the information asked for regarding the newest form of arrester which he had described. Some written communications were also received, among which one from Mr. E. A. WATSON containing an explanation of the large number of gaps required in arresters of the multi-gap type. One or two engineers connected with actual high-tension distribution systems took part in the Manchester discussion, and a good deal of practical information was elicited. (Page 228.)

Two articles, dealing with the fluctuation in candle-power with pressure variation for carbon and metallic filament lamps, have been published recently—one in Germany and one in America. The former points out that a simple relation exists between the percentage fluctuation in candle-power and the percentage pressure variation, and compares various types of lamps on this basis, and the latter contains tables showing the percentage variation of resistance, current, candle-power, and energy consumption with percentage pressure variation. (Page 233.)

A PATENT specification by Mr. A. F. BERRY, published last Thursday, describes an interesting system of electric heating and cooking by alternating currents, in which a metal "hot plate" is heated principally by eddy currents induced by an embedded winding. (Page 235.)

THE water-power generating station at Trezzo, Italy, contains an equipment of nine 1,000-kw. alternators driven by low fall vertical shaft turbines. Owing to the sharp bend in the River Adda, very simple hydraulic arrangements are possible. A steam reserve plant is also provided. In the switchgear a somewhat more elaborate arrangement of bus-bars is used than usual, and a feature of the transmission system is the employment of iron wire for short branch lines. (Page 237.)

A NEW surface contact system is being developed under the patents of Mr. D. SUCHOSTAWER. (Page 239.)

SOME new designs of motor control switchgear are described in an illustrated article. (Page 240.)

THE Paper by Messrs. T. F. WALL and S. P. SMITH, which has been discussed recently before the Newcastle and Birmingham Local Sections of the Institution of Electrical Engineers describes some experiments made to determine the magnitude of the eddy-current losses in the pole shoes of generators and motors. The results emphasise the importance of the ratio of the width of slot to the radial depth of air-gap. The losses increase very rapidly, if the pole shoes are not laminated, after this ratio reaches a value of about 2·0. These losses are some 50 per cent. higher at full load than at no load. In the discussion at Newcastle, Dr. THORNTON suggested that experiments should be made to determine the influence of the shape of the pole shoe. Mr. TURNBULL said that for economy the ratio of slot-width to air-gap should be considerably over 1·5. Mr. HUNT referred to the experiments made by Dr. THORNTON to determine the depth to which the flux surgings penetrate. Mr. CARTER stated in a communication that laminated poles were really cheaper than solid pole shoes. (Page 241.)

A NEW system for ensuring electrical continuity in non-screwed conduit is described. (Page 244.)

THE British Aluminium Co. have now three works in operation for the manufacture of metallic aluminium—two in Scotland, and one in Norway. The price of aluminium is now considerably lower than it was last year, and although copper is reduced in price, aluminium is claimed to be cheaper for current carrying purposes than copper. In America the production of aluminium for the year 1907 was considerably more than for 1906, but the amount of copper produced was rather less, although the value owing to the enhanced price was greater. The patents describing the preparation of boron carbide, and a method for electrolytic etching, are also given under ELECTROCHEMISTRY AND ELECTROMETALLURGY. (Page 244.)

UNDER "Electrical Science," in the British and American section, is an abstract of an important discussion of the method of demagnetising by reversals. In the Papers abstracted in the Continental section, HEYDWEILLER discusses the damping and "resistance" of sparks, SCHOTT deals with the influence of sudden accelerations on the "mass" of electrons, RITZ gives some additional hints regarding the magnetic theory of spectrum lines, and WEISS AND PLANER discuss the disappearance of rotational hysteresis in very strong fields. (Page 245.)

AMONGST the patent specifications published last Thursday was one by THE BRITISH ELECTRIC PLANT CO. & OELSCHLÄGER for a special arrangement of the magnetic circuit of the commutating poles in dynamo-electric machines, and another by ANGOLD & THE MAXIM ELECTRICAL CO. for improvements in the flame arc lamp, full particulars of which have already been given in ELECTRICAL ENGINEERING. Others dealing with electrolytic meters, flywheel buffer machines, conduit wiring, the earthing of transmission systems, and finally one dealing with the decarbonisation of tungsten filaments, are abstracted. (Page 246.)

THE poll of ratepayers in connection with the proposed purchase of the Whitewell and Cavehill tramways by the Belfast Corporation has resulted in a majority of 112,150 in favour. The Bristol Corporation has decided to oppose the Bristol Tramways Co.'s Bill for an extension of time to construct tramways authorised in 1904 on the ground that the company has not shown sufficient activity in dealing with the powers they already possess. In connection with the complaints as to vibration from the electricity works by adjoining owners of property, the Colchester Corporation denies liability. It has been found that the meters registering the current supplied to the Croydon Corporation tramways have been registering about one unit per car mile instead of 1·29 units per car mile. The interesting point is that the tramways undertaking was purchased from the British Electric Traction Company on the former basis. Penalties amounting to £1,465 have been deducted from payments due to Messrs. R. W. Blackwell, owing to the contract time for the construction of certain of the Derby Corporation's tramways having been exceeded. The Electrical Engineer to the Eastbourne Corporation has presented a report in which he states that the increasing use of Osram lamps will tend to reduce the revenue, at any rate for the present. A combined refuse destructor and electricity works were opened on Friday at Greenock. The chairman of the Hull Electricity Committee resigned on Thursday in consequence of the rejection by the Council of the recommendation by the Electricity Committee to accept tenders of a German firm of dynamo makers. (Pages 247-249.)

Digitized by Google

The Aston Corporation invites tenders for a 2,000 kw. turbo-alternator; the sum of £102,418 is required for telephonic and telegraphic developments in Australia; an additional electric lift is to be provided on the West Cliff at Bournemouth; Darwen Corporation will shortly be inviting tenders for a 750 kw. steam-generator and motor-driven centrifugal pump; the Handsworth Corporation require a 315 kw. generator set; Leipsig Town Council will erect an electric lighting and power works at a cost of £1,000,000; Salford Corporation propose to spend £20,000 on the tramway undertaking. A loan of £25,000 will be applied for by the Stalybridge, &c., Joint Board. (Page 249.)

The report of the National Telephone Co., for the half-year ended December 31st, 1907, shows a gross revenue of £145,346. The net result, after deducting £132,621, Post Office royalties, is a profit of £474,236. The directors of the Smithfield Markets Electric Supply are still unable to recommend a dividend out of the balance of £3,337, in consequence of the uncertainty of the future of the company, whose licence expires in a few years' time. The expenditure upon electrical working by the North Eastern Railway Co., for the half-year ended December 31st, 1907, was £17,467. Meetings of the debenture holders of the Brush Electrical Engineering Co. were held on Thursday to consider a resolution for consolidating the company's debentures, but owing to the absence of a quorum the meetings were adjourned. An advisory Committee has been appointed to confer with the Board of the Underground Electric Railways Co., of London, in devising a scheme for dealing with the profit-sharing secure notes, and the financial requirements of the company generally. At the ordinary general meeting of the Central London Railway Co., on Wednesday last week, it was stated that the directors have decided to charge against revenue the sum of £25,300, which has been incurred in the various proposals before Parliament to extend the line, an idea which has now been abandoned for the present. The falling off of the number of passengers carried by the Great Northern & City Railway Co. during the past half-year—namely, 358,749—was attributed by the Earl of Lauderdale at the meeting on Thursday largely to the competition of the London County Council tramways in the north of London since their conversion to electric traction. At the meeting of the City & South London Railway Co. on Tuesday a substantial increase in the receipts was recorded in consequence of the opening of the Euston extension, but owing to the extra charges to be met on capital account, the additional revenue was more than counterbalanced. (Page 251.)

In the House of Commons last week the Postmaster-General stated that there was an understanding that the Radio-Telegraphic Convention would not be ratified without simultaneous ratification by certain other Powers, but that these did not include the United States. A statement with regard to the opposition concerning the proposed purchase of the Whitewell & Cavehill Tramways Co. was made in the House of Commons on Monday by Mr. Birrell. The report of the committee appointed by the Treasury to inquire into the work performed by the National Physical Laboratory has been presented to Parliament. (Page 252.)

Owing to the state of affairs in Portugal, the International Telegraph Conference, which was to have been held in Lisbon in April, is postponed. (Page 253.)

A good deal of light on the progress of the tramway industry is shown by the publication of the annual return of statistics connected with the tramways and light railways of this country up to as late a date as complete information is available. We abstract the figures in an article on another page, where attention is drawn to the directions in which developments have taken place. During the last 15 years there have been two great changes in the conditions of tramway working, electrification, and municipalisation. The former is the more vital, general, and important; the change in ownership has been neither so extensive nor so rapid as that in motive power. Both have contributed to the developments revealed by the comparative tables in the report, but it would be practically impossible to disentangle in them the effects of the two great changes. The rough coincidence in time of the introduction of electric traction and municipal ownership has arisen from the operation of the purchase clause (Section 43) of the Act of 1870. The 21 years, at the end of which the local authorities could purchase at the "then value" of the structure, were nearing their end in the early 90's in the case of many of the pioneer companies. Although it was then clear that electric traction must come, it was equally clear that the companies could not raise the capital needed, when all hope of resultant prospective profits was denied them. Therefore electrification was deferred until the local authorities either purchased the lines, or decided not to purchase immediately, and entered into agreements deferring the purchase time for a sufficient period to justify the companies in electrifying. The particulars contained in the returns demonstrate clearly how the effect of electrification on British tramways as a whole has been an enormous increase of their public utility, coupled with a large diminution of cost per unit of service. When it is remembered that the tramways are nearly all urban, and that but a short length is worked at its maximum utility, it must be apparent that we are not nearly at the end of the benefits of electric traction on roads. The immediate problem is to extend these benefits to the rural population without excessive capital expenditure, a problem the solution of which is far more dependent upon legislators and local authorities than upon engineers, and seems to many thoughtful people a necessary condition of that improvement and repeopling of rural areas, and coincident relief of urban congestion which all parties agree is urgently required by the body politic.

One of the most important points wherein the metallic lamp filament differs from that made of carbon, apart from its great superiority as regards efficiency, is the fact that its brilliancy is much less affected by variations of supply voltage. Not only is the falling off in the light for the same percentage drop of voltage much smaller, but, as is of scarcely less importance, the effects of overrunning are not so serious. On another page will be found results of quantitative investigations of this effect conducted independently in Germany and in America, but, on the whole, in excellent agreement. From these the general law governing these changes may be traced. The advantages from the consumer's point of view of a diminution in the variations of light, which are only too familiar with the carbon filament lamp, are obvious, but the wider question may be raised as to whether the extended use of metallic filament lamps may not enable the Board of Trade to extend somewhat the range of voltage variation permissible on supply mains. In the case

Digitized by Google

especially of outlying districts, this would lead to economies in expenditure on mains of a magnitude greater than would appear at first sight. The improvements constantly being made in the construction and suspension of the new filaments, tending to diminish their susceptibility to shock and vibration, should also open up a field for their use for electric tramway and railway work where fluctuations of voltage are unavoidable. For train lighting from accumulators or self-regulating dynamos, the metallic filament has already made considerable headway, as well as on a smaller scale for omnibus and carriage lighting, and here again the advantage is felt of a lessened diminution of candle-power as the battery voltage falls than was obtainable with our dear old friend the carbon filament.

THE discussion on Mr. J. S. PECK's Paper on Thursday last showed that a good deal more interest is taken in the protection of high-tension transmission circuits than is generally supposed. We have reason to know that the increasing use of overhead lines is resulting in serious inquiries from the engineers responsible for them as to the precautions necessary. Although it is correctly said that severe thunderstorms are of rare occurrence in this country, as compared with the tropics, and some other regions, it has been found necessary from the earliest days of electric telegraphy to defend the wires and instruments against lightning damage. The most effective device for that purpose is the "earth wire," which is a distinctive feature of British telegraph construction. This saves poles and insulators from destruction, but a good deal of damage is annually done to instruments and underground cables by the portions of the discharges carried off by the line wires. One of the earliest lightning arresters used to protect telegraph instruments had a quantity of powdered graphite between electrodes connected to line and earth respectively. This arrester is somewhat on the "coherer" principle desiderated by Mr. ALEXANDER RUSSELL. Occasionally it failed to "decohere," and shunted the instrument to a serious degree, but a few taps restored the high resistance. It is evidently not very easy to adapt such an arrester to high-tension apparatus with a great power behind it, but Mr. PECK's description of the carborundum block arrester indicates an attempt to utilise the idea for moderate pressures. Damage by lightning is fairly frequent on certain tramways, where arresters in feeder pillars are occasionally blown to pieces. The arresters on cars are less often damaged, probably because there is more surface leakage from the trolley standard and the car wiring than from the side feed cables. There are considerable electrical disturbances in the atmosphere, besides those associated with thunderstorms, which have not been very systematically investigated, although meteorologists recognise that the vertical potential gradient in the air is connected with weather changes, and record it constantly at certain stations. Nearly seventy years ago ANDREW CRASSE set up masts and lengths of insulated wire near Taunton, and recorded the sign and potential of the charge collected for considerable periods. Reference to his work will show that very high pressures were not infrequent, and that his wires sometimes collected considerable currents from the atmosphere. His measurements by spark length and electroscopes indicate potentials up to 70,000 volts, as occurring during fogs, snow and hail storms; and from lengths of collecting wire, varying between 1,600 and 8,000 feet, currents of sufficient strength to decompose water and fuse fine iron wire were frequently obtained. An overhead arc light circuit on the east coast has been known to give off $\frac{3}{8}$ in. sparks for hours on end, though not particularly well insulated, and with the very high insulation required for extra high-tension lines and apparatus, it seems likely that such atmospheric effects may give occasional trouble. Mountainous districts, where the lines connect different altitudes, may be expected to suffer most frequently, and this is borne out by the experiences in India, referred to by Col. CROMPTON. The water-jet discharger would appear to have some advantages in dealing with such cases, as the potential changes are comparatively gradual, and a high resistance leak circuit will generally carry off the small current collected by the wires.

ARRANGEMENTS FOR THE WEEK

(TO-DAY), THURSDAY, FEBRUARY 13TH.

Royal Society.

4.30 p.m. Meeting at Burlington House. Among the Papers to be read are the following—(1) "The Constitution of the Electric Spark," by T. Royds; (2) "The Effect of Hydrogen on the Discharge of Negative Electricity from Hot Platinum," by Prof. H. A. Wilson, F.R.S.

Rugby Engineering Society.

8 p.m. Ordinary Meeting. Paper to be read:—"Mechanically-propelled Commercial Vehicles, with Special Reference to the Petrol Electric System," by Bernard Hopps.

FRIDAY, FEBRUARY 14TH.

Northampton Institute Engineering Society.

5.45 p.m. Meeting at the Institute, Clerkenwell, E.C. Paper to be read:—"Some Problems of Electric Railway Operation," by E. V. Panell.

Physical Society.

8 p.m. Annual General Meeting at the Royal College of Science, Imperial Institute Road, South Kensington.

SATURDAY, FEBRUARY 15TH.

Institution of Electrical Engineers: Students' Section.

10.30 a.m. Visit to the National Physical Laboratory.

MONDAY, FEBRUARY 17TH.

Institution of Electrical Engineers: Leeds Local Section.

7.30 p.m. Meeting at the University, when Mr. J. F. C. Snell's Paper, read in London, on "The Cost of Electrical Power for Industrial Purposes," will be discussed.

TUESDAY, FEBRUARY 18TH.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Meeting at the University. Paper to be read:—"Direct Current Turbo-Generators," by W. Hoult.

Post Office Engineering Department.

7.30 p.m. Annual Dinner at the Grand Hotel, Trafalgar Square, W.C.

THURSDAY, FEBRUARY 20TH.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, S.W. Papers to be read:—(1) "Electrical Power in Railway Goods Warehouses," by H. Henderson. (2) "Electric Power in Docks," by C. E. Taylor.

FRIDAY, FEBRUARY 21ST.

Electro-Harmonic Society.

8 p.m. Concert (ladies' night) at the Bechstein Hall, Wigmore Street, W.

Institution of Mechanical Engineers.

8 p.m. Annual General Meeting at Storey's Gate, St. James's Park, London. The following Paper will also be read and discussed:—"Tests of a Live Steam Feed Water Heater," by Prof. John Goodman.

Royal Institution.

9 p.m. Evening Discourse by Sir Oliver Lodge on "The Ether of Space."

SATURDAY, FEBRUARY 22ND.

Birmingham and District Electric Club.

7 p.m. Meeting at the Municipal Technical School, Suffolk Street, Birmingham. Paper to be read:—"The Electro-deposition of Silver," by T. J. Baker.

TRAMWAY RETURNS FOR 1906-1907

THE annual return of tramways and light railways for the year ended December 31st, 1906, for companies, and March 31st, 1907, for municipalities, which has just been issued, shows a further increase in traffics and other figures. The passengers carried number 2,454,807,487, the gross receipts £11,849,175, and the capital expended £64,092,091. Out of 2,394 route miles open for service, 2,195 are worked electrically, whilst the number of horses has fallen from 9,786 in 1905-6, to 7,378 in 1906-7. It may therefore be said that tramway electrification is practically complete in the United Kingdom, and as the work has been in progress since the early 90's, but only on a large scale since 1898, it is a good time to look back on the figures of past years, and see what they tell as to the effect of electrification as compared with the older methods of traction. The "Comparative Table" in the front of the return groups the more important figures for the years 1878, 1886, 1894, 1898, 1902, 1905-6, and 1906-7, and affords a convenient assemblage of data for comparison.

In the "Prefatory Memorandum," which introduces the return, an attempt is made to distinguish an intermediate "Steam Period" between the "Horse" and "Electric Periods." But, in fact, there never has been a "Steam Period" in British tramways generally. The year chosen to represent "Steam" is 1898, in which the number of steam locomotives reached the maximum of 589. But the same year shows the maximum number of horses in service, and that they had increased at a greater rate than the engines. In certain districts there was a "Steam Period" generally without a preceding "Horse" period. To show what steam traction did, it would be necessary to separate out the steam lines. These were a great boon to the public of the districts served, districts mostly hilly and of the manufacturing class. They generally paid their shareholders well, but were too objectionable to eye and ear to be tolerated generally.

The most striking figures in the comparative return are, of course, those which show the wide extension of public utility of the tramway system due to electrification. The most significant figures in this respect are those of the number of passengers carried annually. The figures given are as follows to the nearest million:—

Year—	1878.	1886.	1894.	1898.	1902.	1905/6.	1906/7.
Millions of passengers	146	384	617	858	1,394	2,236	2,455

Although a few short tramways were electrified between 1883 and 1885 (a total length of about 15 route miles), the process was not at all general until the late 90's, and 1894 may be roughly classed as in the pre-electric period. By 1898 the mileage electrified had risen to about 163, route, or about 16 per cent. of the whole length in service, of which 89 miles were new lines, so that the large increase in passengers between 1894 and 1898 coincides with the commencement of effective electrification. The difference made to the rate of progress will be better appreciated when it is noted that the increase in the twelve years between 1886 and 1894 was 233 millions, or, say, 19½ millions per annum, and in the four years between 1894 and 1898, 251 millions, or, say, 63 millions per annum.

Since 1898 the increase of passengers has been at the rate of 200 millions or more per annum, and the enormous total for the last year represents an average of 60 journeys per head of the population of the United Kingdom. Measured by journeys, then, tramways now render four times the public service that they did in 1894. But this is not nearly the full measure. The average length of a tramway journey has undoubtedly increased, whilst the average cost has diminished. Statistics as to the length of journey are not available, but the average fare paid has fallen from 1·41d. in 1894, to 1·10d. in 1906-7. There is an intimate connection between reductions of fares and increase of traffic, but without electric traction the reductions in fares would not have been possible, and probably without electric traction there would have been much less municipalisation. The extension of the useful range of tramways in virtue of the higher speed is another consequence of electrification. So that while municipalisation has had an important share in the progress, to electrification must be attributed the major part, and even the possibility of successful municipalisation.

The increased public service rendered is attributable in a great degree to the greater potential carrying power of electric tramways due to factors which it is unnecessary to recapitulate here. That this carrying power is utilised in widely varying degrees is well known, and the following figures of mileage passengers and passengers per route mile only indicate what has been and is now done, but by no means what can be done.

Year—	1878.	1886.	1894.	1898.	1902.	1905/6.	1906/7.
Route miles ...	269	865	975	1,064	1,484	2,240	2,394
Millions of passengers	146	384	617	858	1,394	2,236	2,455
Thousands of passengers per mile	543	444	633	806	939	998	1,025

Great as the increase in passengers carried per route mile has been, it has been lessened by the extension of lines into comparatively "thin" areas. The L.C.C. electric routes carry at the rate of about 4¼ million passengers per mile per annum, so there is still plenty of spare capacity available.

The greater utility of electric lines is also well shown by the greater number of passengers carried annually per car in service. Taking 1894, the latest year given in which the number of electric cars is known to have been insignificant, and the year 1906-7, in which the returns give the figures as 10,369 "Electric," and 1,377 "Non-electric," the relative figures are:—

Year—	1894.	1906/7.
Millions of passengers	617	2,455
Cars in service...	4,179	11,746
Passengers per car	147,600	209,000

This, again, does injustice to electric traction, because a much larger reserve of cars is kept available for rush hours and holiday traffic than was commercially practicable in the horse days, when it was useless to keep cars unless horses were also available, and horses standing idle or underworked mean a good deal in working expenses.

Looking at the other side of the account, it is interesting to see what this increase of public usefulness, due mainly to electrification, has cost on capital account. The total capital expended on tramways has increased nearly sixteenfold since 1878,, and the relation between this expenditure, the mileage open, and the traffic carried is tabulated below:—

Year—	1878.	1886.	1894.	1898.	1902.	1905/6.	1906/7.
Capital expended in £1,000's ...	4,207	12,573	14,389	16,493	31,562	58,178	64,092
Route miles open	269	865	975	1,064	1,484	2,240	2,394
Capital per route mile	£15,640	£14,720	£14,710	£15,450	£21,270	£25,970	£26,770
Capital per passenger carried.	6·91d.	7·86d.	5·60d.	4·61d.	5·43d.	6·24d.	6·26d.

Whilst the expenditure per route mile has largely increased, and is now nearly double what it was at the minimum of 1894, the service rendered has also increased, though not so fast. As the fare received per passenger has fallen from 1·41d. in 1894, to 1·10d. in 1906-7, the growing relative importance of capital charges is made apparent in a somewhat novel way by the above table, which shows that while in 1898 each

Digitized by Google

passenger carried had the equivalent of the use of 4·61d. for a year, in 1906-7 each had the equivalent of the use of 6·26d. for a year.

The working expenditure, on the other hand, has decreased, as shown below:—

Working expenditure—						
1878.	1886.	1894.	1898.	1902.	1905/6.	1906/7.
£868,315	£2,021,556	£2,859,056	£3,507,895	£4,817,783	£6,835,713	£7,363,762
Working expenditure per passenger—						
1878.	1886.	1894.	1898.	1902.	1905/6.	1906/7.
1·43d.	1·26d.	1·11d.	0·98d.	0·83d.	0·73d.	0·72d.

so that each passenger in 1906-7 cost 0·72d., *plus* the interest and other charges on a capital of 6·26d., whilst in 1898 each cost 0·98d., *plus* the interest and other charges on a capital of 4·61d. As the saving in working expenditure—0·26d.—is nearly 16 per cent. on the extra capital employed, it is hardly disputable that the total cost has been reduced. To follow the figures into net receipts and proper capital charges would involve the discussion of somewhat controversial subjects, which are beyond the present purpose.

THE NEW TELEPHONE CHARGES

A DEPUTATION, organised by the Newcastle Chamber of Commerce, was received by Mr. Sydney Buxton, Postmaster-General, in the Grand Committee Room of Westminster Hall, on Tuesday. The object of the deputation, which was introduced by Lord Joicey and was representative of all the different commercial interests in the Kingdom, was to urge that a Select Committee should be appointed to inquire into the system of telephone rates and the future telephone policy.

Mr. HERBERT SHAW (Newcastle Chamber of Commerce) complained that the new rates had been put into force too suddenly. As a result of the new tariff, subscribers making 13 calls a day would have to pay £15, an increase of nearly 100 per cent., and he understood that a charge of £5 for 15 calls was profitable. The delegates were emphatic in their opinion that the flat-rate system must be maintained, and that a measured rate should be optional.

Mr. D. M. STEVENSON (Glasgow Corporation) said that they objected to the Treasury making money out of telephones, because they considered that an interference with trade. Wherever the Post Office had the service concurrently with the National, they had raised the rate. The delegates were agreed that 10,000 calls a year was not an unreasonable number. With regard to future policy, they hoped that all localities who chose to carry on the local exchanges would get an opportunity of buying them or leasing them.

Mr. BUXTON, in reply, assured the deputation that the Post Office desired to give a very efficient telephone service at the cheapest possible rate. He would say that, with regard to the small users, the new system was cheaper than the old flat-rate. The only places in which the Post Office had adopted the higher rates of the National Telephone Company were where the Post Office had no exchange, and therefore had no option in regard to the matter. As the demand of the telephone user was so varied, it was clear that a fixed rate, which was calculated to cover the average cost, if each subscriber paid the same amount, must be unduly favourable to some subscribers and excessively burdensome to others. In a very large number of cases of large users the charge amounted to only a fifth of a penny per call, whereas the measured service worked out at a penny per call, and now a halfpenny call was proposed. The cost of the actual message might be put at something not below a halfpenny per call; consequently the large users on the flat-rate were being charged less than cost price. The subscribers who were using 3,000 calls during the year five years ago had now increased their calls to 11,000. In no case had they taken a second line, and they were paying no more now for their 11,000 calls than they were for their 3,000 calls five years ago. The result was that about 20 per cent. of the ineffective calls due to engaged lines was due to the overloading of the lines by such subscribers. Other countries had abolished the flat-rate system, and Germany was doing so as well. It was proposed to leave the present flat-rate subscribers under the present conditions. If they had the two systems side by side, all the large users would go into the flat-rate, and unless the flat-rate was raised heavily, where would be the revenue for the Post Office? The Post Office authorities were not putting the measured rate up, but the large users on the flat-rate system would have to pay a larger amount than at present. If they could abolish the existing flat-rate system, the measured rate could be materially lowered. They would not be in a position to say how much the measured rate could be lowered until 1912. With regard to the telegraph system, the rates were reduced, and that system was being carried on at a very serious annual loss.

PRICE OF ELECTRICAL ENERGY IN LONDON

A PARLIAMENTARY return of the amount of electrical energy delivered and the average price charged per unit by local authorities and companies in the Metropolitan Police District during their last completed year of account, has been issued. Information is given of the number of units delivered for power and heating, private lighting, and public lighting respectively, and the average price obtained in each case. The local authorities included are those of Battersea, Bermondsey, Fulham, Hackney, Hammersmith, Hampstead, Islington, Poplar, St. Marylebone, St. Pancras, Shoreditch, Southwark, Stepney, Stoke Newington, Woolwich, Acton, Barking, Barnes, Beckenham Bexley, Croydon, Ealing, East Ham, Epsom, Erith, Finchley, Heston and Isleworth, Hornsey, Ilford, Kingston-upon-Thames, Leyton, Surbiton, Walthamstow, West Ham, Willesden and Wimbledon. Dealing with the figures given for these local authorities only, the average prices obtained in the above districts were as follows—for power and heating, 1·301 pence per unit; for private lighting, 5·677 pence per unit; and for public lighting, 1·850 pence per unit. For the total number of units delivered, an average price of 2·563 pence per unit was obtained. The lowest charge for power and heating was that of West Ham, where 1·4 million units were sold at an average price of 0·95 pence per unit. This borough had, however, an output for traction of nearly 4 million units, and an output for lighting of over 2 million units during the year, the average price obtained being 1·0 and 2·7 pence per unit respectively.

The lowest charge for private lighting was that of Fulham, where 1·1 million units were sold at an average price of 2·1 pence per unit. St. Marylebone, with the largest output of 7·5 million units for lighting, obtained an average price of 4·91 pence per unit (including, however, meter rental charges). The highest charge was that of Bexley, where 730,000 units were sold at an average price of 5·65 pence per unit. The lowest and highest charges for public lighting were as follows:—The lowest charge was that of Stepney, where one million units were sold at an average price of 1·29 pence per unit; the highest charge was that of Epsom, where 95,000 units were sold at an average price of 4·3 pence per unit. The lowest average charge for all purposes was that of West Ham, where over 8 million units (the largest total output) were sold at an average price of 1·48 pence per unit; St. Marylebone, with a total output of 8 million units, obtained an average price of 4·7 pence per unit, but, as above stated, 7·5 million units, *i.e.*, nearly 94 per cent. of the total output, was for private lighting. This was the highest average price obtained.

Passing next to the supply by power companies, the following electric light and power companies are included, as supplying energy in the Metropolitan Police District:—Brompton and Kensington, Charing Cross, West End and City; Chelsea, City of London, County of London, Kensington and Knightsbridge, London Electric Supply, Metropolitan, Notting Hill, St. James's and Pall Mall, South London, South Metropolitan, Westminster, Bromley (Kent), Chislehurst, Chiswick, Harrow, North Metropolitan Electrical Power Distribution, North Metropolitan Electrical Power Supply, Northwood, Richmond, South Metropolitan Electric Tramways and Lighting, Twickenham and Teddington, and the Uxbridge and District. The average prices obtained by the above companies were as follows:—For power and heating, 1·45 pence per unit; for private lighting, 3·853 pence per unit; and for public lighting, 1·62 pence per unit. For the total number of units delivered, an average price of 3·034 pence per unit was obtained. The lowest charge for power and heating was that of the Westminster Electric Supply, and the St. James's and Pall Mall Electric Light Co., 1·0 pence per unit being the price in both these cases. The outputs were 2,500,000 and 670,000 units respectively. The lowest charge for private lighting was that of the City of London Electric Lighting Co., by which 14·5 million units were sold at an average price of 3·11 pence per unit. The highest charge was that of the Chislehurst Electric Supply Co., by which 98,000 units were sold at an average price of 6·9 pence per unit. For public lighting the lowest charge was made by the St. James's and Pall Mall Electric Light Co., by which 191,000 units were sold at an average price of 0·721 pence per unit. The highest charge was that of the Charing Cross, West End, and City Electricity Supply Co., by which 454,000 units were sold at an average price of 2·93 pence per unit. Out of the twenty-four companies included, only eleven supplied for public lighting. The lowest average charge for all purposes was that of the North Metropolitan Electrical Power Supply, the total output (5·5 million units) of which was entirely for power purposes; and the average price obtained was 1·39 pence per unit. The City of London Electric Lighting Co., with the largest total output (22 million units), of any company or local authority, obtained an average price of 2·65 pence per unit.

Taking the figures for both local authorities and supply companies in the Metropolitan Police District, the following average prices were obtained. For power and heating, 1·388 pence per unit; for private lighting, 3·777 pence per unit; for public lighting, 1·802 pence per unit. The total amount of energy delivered, during the year, in the whole district, was 213 million units, and the average price obtained was 2·85 pence per unit.

UNDERGROUND ELECTRIC RAILWAYS OF LONDON

BAKER STREET & WATERLOO RAILWAY.—The directors' report for the half-year ending December 31st, 1907, shows capital expenditure during the half year of £161,044 18s. 11d. The gross receipts amounted to £69,249 8s. 11d., an increase of £24,689, or 55·5 per cent. on the gross receipts in the corresponding half of 1905. The working expenditure (including rates and taxes) has been £45,925 11s. 7d. No detailed comparison with the expenses in 1906 is given in the accounts, as in 1905 the company were not bearing, as they now do, the whole of the revenue expenditure. After providing for interest and rents, and crediting to net revenue account the sum of £2,440 16s. 10d. receivable from the Underground Electric Railways Co. of London, Ltd., under their guarantee agreement, there remains a balance of £17,670 9s., available for dividends, and the directors recommend that a dividend at the rate of 4 per cent. per annum be declared on the preference shares, and that a dividend at the rate of 3 per cent. per annum be declared on the ordinary shares other than those held by the Underground Co. or their nominees, who have consented thereto. The directors propose that these dividends shall be payable on February 24th 1908. The following gives the number of passengers carried since the opening of the railway, including estimated journeys by season ticket holders :—Half-year ending June 30th, 1905 (16 weeks), 3,006,276; half-year ending December 31st, 1906, 6,799,895; half-year ending June 30th, 1907, 9,956,995; half-year ending December 31st, 1907, 10,662,876. Further progress has been made with the extension of through booking facilities, and arrangements have been made with the following companies :—Great Northern, Piccadilly & Brompton Railway, Charing Cross, Euston & Hampstead Railway, District Railway, Central London Railway, Metropolitan Railway, City & South London Railway, London & South-Western Railway (some stations). Negotiations are also in progress with other railway companies for a joint scheme of advertising, so as to encourage and develop the use of all the urban railways as one comprehensive system. The meeting will be held on Monday.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY.—The report for the half-year ending December 31st, 1907, shows capital expenditure during that period of £82,731 3s. 2d. The gross receipts amounted to £74,328 8s. 9d., and the working expenditure (including rates and taxes) has been £61,353 17s. 9d. The following gives the number of passengers carried since the opening of the railway, including estimated journeys by season ticket-holders :—Half-year ending June 30th, 1907 (8 days), 421,466; half-year ending December 31st, 1907, 9,881,357.

METROPOLITAN DISTRICT RAILWAY.—The expenditure on capital account during the half-year has been £99,645, but, after deducting £186,305 received from sale of lands, &c., there is a net credit to capital account of £86,659. The gross receipts amount to £224,463, being an increase of £8,617 on the receipts for the corresponding half of 1906. The working expenses amount to £156,069, being an increase of £350. After providing for rent charges, interest on debenture stock and other charges, the net revenue account shows a deficit of £34,591. To this deficit must be added the sum of £10,937, being the company's proportion of net revenue arising from the City Lines Joint Undertaking, which, although included in the net revenue account, is not available for payment of Debenture interest, being specially appropriated to the payment of dividend on the Four per Cent. Guaranteed stock. With the above-mentioned addition, the deficiency for the half-year chargeable to capital under the company's statutory powers is £45,328. The dividend payable on the Four per Cent. Guaranteed stock is at the rate of £1 15s. per cent. per annum. The arrangements with the Great Northern, Piccadilly and Brompton Railway Company for the user of this company's widened lines between West Kensington and Hammersmith, and for the grant of rights of user of South Kensington, Gloucester Road and Earl's Court stations, which have been referred to in several half-yearly reports since 1903, have now been finally adjusted and embodied in formal agreements. These agreements comprise the sale to the Brompton Company of lands for their car-sheds at Lillie Bridge, and for stations and sidings. The compensation payable by the Brompton Company for the lands and rights acquired by them, other than the right of user of the widened lines to Hammersmith, and for works carried out by the District Company in connection with the provision of accommodation for the Brompton Company has been settled at £165,999, including interest up to June 30th, 1907, and this amount has been paid and credited to capital. The negotiations with the London, Tilbury and Southend Railway Co. in regard to the payment by that company for the working of the District Company's rolling-stock on the Tilbury line, which were referred to in the directors' report for the half-year to December 31st, 1906, have now been satisfactorily completed, and the terms settled for a period of five years. The two high-tension cables, extending from Earl's Court to Whitechapel, which carry electric current for the use of the Tilbury Company, and the ducts in which these cables are placed, have been sold to that company at the price of £18,110, and this sum is credited to capital. During the past half-year the directors have given much consideration to the financial position of the company. They are unable, under existing powers, to raise further moneys to meet the recurring deficits on revenue account and to provide for all the financial requirements of the company, and the situation occurs just at the time when there is every reason to believe that the company are about to realise the benefit of their large outlay in recent years upon the electrification and improvement of the railway. Under these circumstances the directors came to the conclusion that the best course in the interest of all classes of stockholders was to submit a statement of the position to the debenture stockholders, and to deposit a Bill in Parliament to enable the requisite funds to be raised by the issue of prior lien debenture stock, ranking next after the rent charge stocks. The directors believe that if authority is obtained to issue the proposed prior lien stock the finances of the company will be placed on a safe footing, and they hope that the scheme which they recommend will receive the approval of the proprietors of the various stocks. Details of the Bill in question were given in our issue of December 26th.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY.—The report for the half-year ending December 31st, 1907, shows that the capital expenditure amounted to £20,727 3s. 4d., the gross receipts to £119,271 6s. 9d., and the working expenditure (including rates and taxes) has been £70,752 19s. 5d. After providing for interest and rents there remains a balance of £7,114 7s. available for dividend, and the directors recommend that a dividend at the rate of 4 per cent. per annum be declared on the ordinary shares other than those held by the Underground Co. or their nominees, who have consented thereto. The following gives the number of passengers carried since the opening of the railway ,including estimated journeys by season ticket-holders :—Half-year ending December 31st, 1906 (16½ days), 806,120; half-year ending June 30th, 1907, 11,953,759; half-year ending December 31st, 1907, 13,914,779. The report continues that the company's traffic is increasing most satisfactorily. The receipts during the four weeks of January in this year show an increase of 55½ per cent. on the receipts for the corresponding weeks in 1907. The construction of the railway having now been completed, to the entire satisfaction of this company, the directors have been engaged in settling up with the Underground Electric Railways Co., of London, Ltd., questions of account relating to the construction contracts. The mutual claims arising out of these questions approximately balance each other, and the directors have come to the conclusion that the best way of dealing with them is to make a general compromise and settlement involving no payment on either side, except a payment of £10,000, which, although not provided for in the construction contracts, the Underground Co. have agreed to make in order to supply the company with working capital on the cancelment of the existing agreement for leasing the undertaking to the Underground Co. An agreement to this effect will be submitted to the shareholders for their approval at the general meeting on Tuesday. The directors have been in communication with the directors of the Underground Co. in regard to the agreement between the two companies, dated January 15th, 1905, under which this company agreed to grant, and the Underground Co. agreed to take, a lease of the undertaking in perpetuity at a rent equal to 4 per cent. per annum on the debenture and share capital of the undertaking. The Underground Co. desire that the above-mentioned agreement should be cancelled. Inasmuch as the Underground Co. or their nominees are entitled to the whole of the share capital of the company except 55,704 shares of £10 each, the directors see no objection to the cancelment of the agreement of January 15th, 1905, on condition that 33,540 of such shares, which are held by shareholders unconnected with the Underground Co., are converted into preference shares bearing a fixed preferential dividend at the rate of 4 per cent. per annum, payable out of the profits of the company in each half-year, and that the Underground Co. guarantee such dividend in perpetuity, and also guarantee payment of the interest on the debenture stock of the company. A Bill has accordingly been deposited in Parliament and will be submitted to the proprietors for approval at the special meeting, to be held after the general meeting on February 18th, by which power is sought to cancel the agreement of January 15th, 1905, and to convert into preference shares on the terms set forth in the last paragraph the 33,540 shares of which the denoting numbers are scheduled in the Bill, and which are held by shareholders other than the Underground Co. or their nominees. The Bill also seeks to enable the company, with the previous consent of the Underground Co., by resolution from time to time, to convert not exceeding 86,460 further shares into preference shares ranking *pari passu* with the above-mentioned 33,540 shares, but (unless the Underground Co. otherwise expressly declare) without the benefit of the guarantee of the Underground Co. to which such 33,540 shares will be entitled.

PROTECTIVE DEVICES FOR HIGH TENSION CIRCUITS

LONDON DISCUSSION.

MR. J. S. PECK'S Paper on protective devices for high tension circuits, read first at Manchester, was discussed at the London meeting of the Institution of Electrical Engineers last Thursday. In the Paper, which was given at some length in our last issue (ELECTRICAL ENGINEERING, February 6th, page 201), the author considered the nature of the "static" strains produced by lightning, switching, grounding, or by any occurrence which causes an abrupt change in static potential, which may appear as high pressure to earth or between wires, or as a concentration of potential upon a portion of the circuit. To relieve the high pressure between line and ground or between wires, lightning arresters are used. To protect apparatus from concentration of potential, choke coils may be placed in series with the apparatus to be protected. Lightning arresters usually consist of an air-gap in series with a current limiting and an arc suppressing device. Four types of lightning arresters are in general use—the horn, the multi-gap, the water-jet, and the electrolytic. The electrolytic is the last type to enter the commercial field, and while the time it has been in active service is short, the author considered that there were indications that it would afford greater protection than any other arrester yet produced.

After reading an abstract of the Paper, Mr. Peck showed a series of lantern slides illustrating some of the forms taken by the protective appliances manufactured by the Westinghouse Company.

Professor G. KAPP (Birmingham University), in opening the discussion, congratulated the Institution upon having had a Paper which was the outcome of a very large amount of experience and experiment, and referred to the happy nature of certain mechanical analogies which the author had employed to make his remarks clear. Mr. Peck had said that the electrolytic lightning protector was charged with a certain electrolyte. He thought all of them would like to know what the electrolyte was, whether it was an alkali, an acid, or what? Also he would like to know what voltage per tray could be allowed as the limit; and, finally, whether the arrangement as represented in Fig. 10 (see page 204, ELECTRICAL ENGINEERING, February 6th), was the usual arrangement. It seemed to him that in this arrangement the electrolytic protector really took the place of a dead resistance, while the protector was the horn. Would the author kindly say in his reply whether the electrolytic protector could be used without the horn? Mr. Peck said that there were waves which returned along the line, especially if there were discontinuity as regards the capacity per unit length, such as at the transition from an overhead to an underground line. As a matter of fact, where there are waves there are nodes and anti-nodes. If you happen to put the lightning protector at a place where there is a node, there is no protection because there is no rise of pressure; so that it is quite possible, if you put only one protector on a line, that it will not protect your machinery if it happens to go on to a node. Therefore the only remedy is to put enough protectors on the line to hit an anti-node somewhere. There was another point he would mention, in the hope of getting some more information. The theoretical rise of pressure on switching off a current was the current multiplied by the square root of the ratio of Henrys upon farads. If that formula were applied to any current, even at the quite innocent pressure of 110 volts, it would be seen that there was an enormous rise of pressure because the capacity was so small. With a continuous current there would be an enormous rise of pressure, but the frequency was also enormously great because the frequency alters inversely as the square root of the capacity. The very great frequency would produce in the iron of the circuit an enormous iron heat loss, and this iron heat was equivalent to an enormous magnetic resistance. So that the case was not so bad, because you had, instead of using the simple formula, to divide by a function of the resistance. There was thus no danger of a continuation of this very high pressure, but, the very first moment the high pressure was there, there was no doubt about it. Yet we switched on 500-volt apparatus in our tramcars every day, and nothing broke down. The only explanation which he could offer was that a high electric pressure, if it only lasts a thousandth of a second, would do no harm. In an alternating line they always had the chance that, in switching, the arc which was drawn by the switch would last long enough for the current to pass through zero. If they switched under oil, the oil seemed to have the property of extinguishing the arc exactly at the time when it went through zero, and thus alternating currents could be switched on much more easily than continuous currents. The speaker had with him part of a horn type of arrester which was designed by Mr. Zapf, of the Land und See Kabelwerke, a sketch of which is shown in Fig. 1. In order to

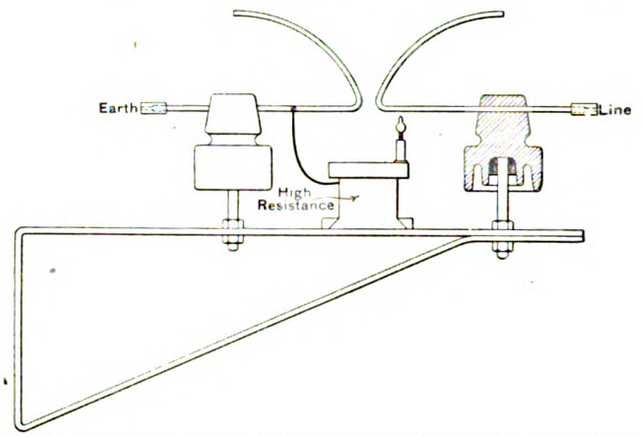

FIG. 1.—DRAWING OF ZAPF LIGHTNING ARRESTER SHOWN BY PROF. KAPP.

make an ordinary arrester go off at a voltage which was not too much above the normal, one had to set the horns so close that anything accidentally coming between, such as a fly or a spider, would sometimes send the thing off. When it went off and the horns were set close, an arc was formed; a little metal was melted, forming a globule, which protruded so that the arrester had to be set again. To avoid this difficulty, Mr. Zapf designed an arrester in which the horns could be set at a suitable distance, such as an inch apart, for 20,000 volts. That by itself, of course, would not go off; but he adopted a kind of trigger arrangement. The earth was connected with a high resistance box, provided with a platinum point with a screw adjustment; this point formed a spark gap which could be set very close. It might be said that the argument of the fly applied here also; it would get in and set that off. It would, but that would not matter, because there was only a very slight discharge owing to the high resistance in series. If the discharge persisted, however, it would ionise the air in the neighbourhood, and the large gap would go off. Prof. Kapp also showed a diagram, reproduced in Fig. 2, to show a method by which the danger of

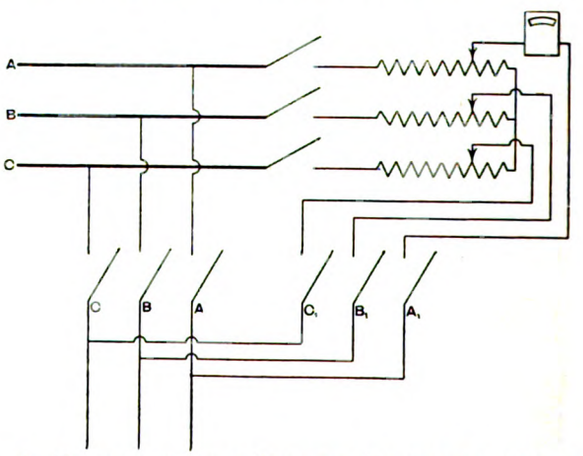

FIG. 2.—DIAGRAM OF CABLE CHARGING ARRANGEMENT SHOWN BY PROF. KAPP.

piling up the volts on the first few portions of an apparatus could be avoided by throwing the volts on gradually. This was done by a sort of auto-transformer, the secondary of which was picked off from points which could be shifted. Thus very few volts could be put on to begin with, so that the charge with the first rush of current would be very small. The contact points were then run along to the end, when they had the same potential as the busbars, and the main switch could be closed. In switching off, the same thing could be done. He had tried this combination apparatus for paralleling dynamos, and found

Digitized by Google

that this was possible without synchronising, even if the speeds were different by as much as 1½ per cent. All that is done is to shift the auto-transformer about a quarter from the end, so that a quarter of the pressure is obtained. The current was so strong that it jerked the machine immediately into synchronism. It was gripped immediately from the busbars and jerked into the proper phase. The whole process could be done in a few seconds instead of many minutes, as in the case where it was necessary to synchronise accurately.

Mr. W. B. ESSON endorsed what the author said about the coils giving way. In his early transmission days this always happened. They had then, however, no step-up transformers, because the pressure was not high enough, and he remembered it was always the coils nearest the line which gave way. This was put down to the fact that the coils simply acted as choking coils, and made the current jump between the terminals instead of going through the wire to find the earth point of the machine. They soon discovered a cure, and it was to do the choking outside the alternator instead of inside. Mr. Peck had dealt with the subject of switching the current on to the apparatus, and Prof. Kapp had also described a very ingenious method of doing this gradually. Such devices had been used for a great many years, but it was not the everyday kind of work that troubled the power engineer; it was the trouble which came on when it was least expected and in a way which was quite unforeseen. As a matter of fact they did not get surges in the lines, when they switched on, to anything like the same extent as when a short circuit took place in the line and the curent was suddenly broken. A short circuit was the greatest stress to which a line could be put, because its effect was to make a very much larger current flow, and consequently a much greater result was produced when the current was broken. Mr. Vaughan, who controlled some of the greatest power transmission plants in the world, comprising 700 miles of line working at 40,000 to 50,000 volts in America, had given this matter great attention, and in a Paper read before the St. Louis Congress he went fully into the question of these surges. He found that under average circumstances the surge pressure in volts due to breaking the circuit amounted numerically to two hundred times the number of amperes which were broken. The curious thing was that as an approximation the rise in pressure was practically independent of the working pressure and length of the line; it depended simply on the current which was broken. From this Mr. Vaughan drew very important conclusions, and showed why it was much easier to work at pressures, say from 50,000 to 60,000 volts, than to work at from 25,000 to 30,000 volts. As the current was only half in the one case, the surge pressure was very much less. With regard to lightning arresters, he had used all three types mentioned in the Paper, but only for very low pressures, but it was in connection with high pressures that difficulties arose. Mr. Vaughan pinned his whole faith on the horn arrester, and he did not think it was too much to say that he had tried multigap and other forms of arresters by the hundred, but found that he could not get them into line for burning up. In fact, Mr. Vaughan had come to the conclusion that any other form of arrester than the horn arrester—he did not believe that Mr. Vaughan had tried electrolytic arresters, however—was only of use when there was no use for it, namely, when there was no lightning. Mr. Vaughan had made some experiments on his line by placing the horn arresters at the power house with 4½ in. gaps, and by short circuiting the lines 100 miles away, he was able to get surges which jumped these 4½ in. gaps. This suggested the question whether in dealing with 50,000 and 60,000 volt pressures lightning arresters were any use at all. In the case of a line insulated for 50,000 volts with a large safety factor, the general impression formed by many engineers was that lightning arresters might almost be dispensed with. In the case he had mentioned of Mr. Vaughan's lines on the Californian Electric and Gas Co. system, the lightning arresters only went at the rate of one a year. In fact, he thought they were only put up there for conscience sake.

Mr. ALEXANDER RUSSELL, dealing with the remarks in the Paper upon resonance, said that the period of the fundamental vibration of a single-phase transmission line was the time taken by light to travel four times the length of the line. Mr. Peck did well to lay stress on the importance of the static charge on a line. One of the main functions of lightning arresters was to get rid of this static charge, which, as the author stated, was due to atmospheric potential. A knowledge of the laws of atmospheric electricity would be essential in order to discuss the relative merits of various lightning arresters. Potential gradient was well known to meteorologists. On an ordinary day in London, taking the earth at zero potential, one metre up would be almost 200 volts, and on a foggy day it would be as much as 1,000 volts. For instance, the tracer of the electrograph at Kew went off the scale whenever the voltage got beyond 750, and on a foggy day it was nearly always off the scale. They could therefore understand, when dealing with an overhead line above the ground, where the potential difference between the stratum of air and the ground might easily be 10,000 to 20,000 volts, that there could be an appreciable static charge induced in that line; and static charge sparked across the arrester and might be followed by an arc. This potential gradient went on diminishing, but the potential went on increasing. At 4,000 metres up, for instance, as meteorologists had found out by numerous balloon experiments, the potential was about 200,000 volts on a quiet day, and on a stormy day, of course, it would be very much more than that. The water-jet arrester, as used in the South of France, seemed to be a very suitable type of arrester for getting rid of the static charge, but he did not think it would be of much use for limiting the pressure between the lines. Its resistance was too high. The electrolytic arrester apparently had the drawback that an air gap in series with it must be used, and he thought that any type of arrester that used an air gap was highly objectionable. They had only to think of the ionisation of the gap that must occur in practice to realise how uncertain the action of such a piece of apparatus must be. It was sometimes stated that lightning arresters were very efficient because continual discharges were taking place. Personally, he thought these discharges must be taking place at the normal voltage. It was simply that the ionisation of the air gap was continually going on on certain days in certain atmospheric conditions, so that the lightning arresters were really a point of weakness in the system. An electrolytic arrester would be very efficient if it had no air gap; it must not be left permanently in the circuit, otherwise heating evaporated the electrolyte and deteriorated the aluminium dishes used. He would like to know what electrolyte was used in the one described in the Paper, because 400 volts seemed to him exceedingly satisfactory. 200 volts was the most that he knew of in connection with any electrolyte with which he was acquainted. Taking 400 volts on a 60,000 volt line, this would mean 250 volts effective; or 240 aluminium cells between the two lines if it were being used as a pressure limiter. This would be rather expensive. An ideal type of arrester would be one of the coherer type. If some powder were invented that offered practically no resistance to the current when the voltage was greater than the normal, and had a higher resistance at the normal voltage or under, this type of arrester would be an ideal type. There had been many references lately in the French technical journals to the Thury type of coherer arrester; he had not read a full description of it.

Mr. W. H. PATCHELL said that the author was very modest in starting with an apology for want of novelty in his Paper, but his name was well known on the other side of the water for many years in connection with the reports got out by the High Tension Committee of the American Institute of Electrical Engineers, and one had only to look at the two important volumes published on this subject to see the part that Mr. Peck had played in the development of this important class of apparatus. The blemish in these reports was that they only commenced in 1903, and the classical Paper by Mr. Thomas referred to by Mr. Peck was unfortunately not included. Then the author put aside his modesty and stated, early in the Paper, that protective devices for high-tension circuits had been carried to a high state of perfection. This was where the commercial man came in; they were told not to wait, but to buy what was available. Then, in the last line of the Paper, the author stated that the electrolytic arrester, which was the last one to enter the field, gave indications that it would afford greater protection than any other arrester yet produced. They thus got to a point which showed that finality had not yet been reached, and this was the fact; it was still in the transition stage. There was no best; some preferred the multi-gap, some the horn type, and some preferred other types. What would suit one condition would not suit another, and because the science had not been reduced to a well-known A B C, many of them had blundered along and made their own experience. Concentration of potential on the end turns of the arrester was a point which the officials of the Charing Cross Co. had had to find out for themselves at Bow. He had mentioned this important matter in the Paper which he read before the Institution in 1905, when he went into the question of surges as far as he could. On this point he would like to ask such a mathematician as Mr. Russell, if the matter was really as simple as he suggested it was. They might get the waves reflected at the velocity of light at the end of lines on the blackboard, but in the line itself they get inductance and capacity and various other idiosyncrasies which they did not get on the blackboard, and perhaps Mr. Russell would reconsider that. Mr. Peck had mentioned switching through a resistance. He believed the first example of this was due to Mr. Ferranti, who had a liquid switch and a tripping switch in series with it. When the switch was closed the coil was tripped, and a flexible conductor was unwound which let a plate down at the bottom of the pot and so short-circuited gradually. The same apparatus was used by Mr. Ferranti for charging cables. Dealing with the various kinds of arrester, Mr. Patchell said the ordinary horn type was worse than useless in many cases. One great trouble was the big flare when breaking. Dr. Kapp had put before them the Land und See Kabelwerke variation of the horn type. He had tried this on alternating and direct current, and the way the little trigger worked was marvellous. In his Paper of 1905, he had mentioned that facing one side of the horn with carbon got over the building up of the metallic bubbles and so upsetting calibration, so that it was possible to work more closely with a carbon-copper horn instead of with the copper horn only. He had tried this up to 40,000 volts, and it was simply marvellous how

Digitized by Google

this gave the same point time after time on the voltmeter. Of course, they must keep changes of temperature, moisture, and that sort of thing away. The non-arcing multi-gap arrester was particularly American. Many people who used them said they had no trouble, but when he had inspected the cylinders he found they had never arced. The author mentioned the necessity for limiting the current. This was the crux of the question. The horn arrester or the multi-gap without resistance was just like the best haulage motor without a controller; the trouble was not so much when the arrester kept going, but when it stopped going. The flow of current, then, was what did the damage, and he had tried dry and liquid arresters, and carborundum and coke, and also dust resistances. Since he left the Charing Cross Co., Mr. Brazil had been carrying on this work. Mr. Mershon said the best resistance for 60,000 volts was a concrete pillar; it did not make much difference whether the concrete was made of flint or rock; this did not have so much effect upon the resistance of the pillar as the size of the material with which the concrete was gauged. The water-jet arrester was largely used in the South of France and Northern Italy, but the author had not mentioned that the common method there was to turn the water nearly off when they did not expect any lightning, and to turn it on when they did. Another objection was that in many places where they got lightning they did not get water. He first saw arresters used in parallel outside the Ontario Co.'s power house at Niagara, and these were due to Mr. Mershon, who had described them in his Paper on the Niagara, Lockport, and Ontario Power Co.'s distribution system. With regard to testing arresters, he thought it was best to do this with a big machine behind them. The author did not mention the very important matter of expense in protecting the protecting devices. It was almost more important to consider the methods of protecting the device adopted than to consider the type of device to be employed. Unless they did this, they got very far astray. For instance, horn type arresters for low tension were impossible out of doors, so that they had to consider whether the arresters were to be placed on the top of the poles or in connection with the switchboard under cover.

Mr. H. BRAZIL said that his remarks applied exclusively to underground cables. The author did not appear to speak very highly of the horn type of lightning arrester, but he had had very considerable experience with them, and would like to say a few words in favour of them. The horn arresters illustrated in the Paper were merely those consisting of two pieces of wire going away at a sharp angle. Mr. Patchell had mentioned arresters in his Paper of 1905 which had two horns, one carbon and the other copper. These were the arresters with which he had had experience, and it was astonishing what degrees of accuracy these could be set to, and also for what a length of time this accuracy could be maintained. The Charing Cross Co. had about 14 or 15 of these arresters in use, and over periods of six months at a time it had been found that, year after year, these arresters retained the same sparking voltage, in spite of a large number of discharges having taken place. Mr. Peck had stated that they took a long time to work. He did not know what Mr. Peck meant by this, for he had found they took from two to four seconds, which he did not regard as a long time. The author also stated that they formed a short circuit on the system. On the Charing Cross Co.'s system it would be bad policy to put them on the circuit without a high resistance of considerable size. The resistance usually consisted of a small rod, like an arc lamp carbon, and it was apt to take any surgings, and was of no value in reducing the strain on the system. He therefore thought that an indicator of some sort was what was required, and Mr. Patchell, in his 1905 Paper, described an indicator which he had had the pleasure of getting out for him. This had now been in use for three or four years on the Charing Cross system, and some hundreds of discharges had been recorded quite satisfactorily. One examination of these records went to show that during the summer—the time of light load—there were a very much larger number of discharges indicated. This, he took it, was due to the fact that the cables were less loaded—*i.e.*, the conditions were more nearly those of open circuit, which were the conditions likely to produce high potentials. The other conditions shown by the indicators were bad paralleling, faulty transformers, &c. Electrical engineers would be surprised at the number of times the pressure rose over 50 per cent. above the normal. With regard to non-arcing arresters, he had examined some of these, and non-arcing was hardly the word for them, as there were very distinct signs of arcing.

Mr. W. M. MORDEY was glad to see from the Paper that the method of protecting transmission lines from lightning by stringing an earthed wire above the line was coming into use again. He asked whether Mr. Peck thought that there was any advantage in the use of barbed wire on the principle that prevention was better than cure. Also, in the case of long transmission lines, was there any advantage in going back to what was done in the early days, and what was always done now in connection with the protection of buildings, *i.e.*, making the buildings as far as possible lightning dischargers, by making the protectors of well-earthed pointed structures to give a discharge of the atmospheric electricity in the same way as an ordinary lightning conductor was supposed to. Was there any experience with any of the long transmission lines with which Mr. Peck had been connected of this kind of protection? Referring to Fig. 9, he asked for some further particulars as to the depth of the dishes.

Mr. L. ANDREWS (Key Engineering Co.) remarked that several of the speakers had referred to the electrolytic type of arrester as if it were something quite new. But this arrester was described in a Paper by Mr. Johnson before the American Institute of Electrical Engineers nearly two years ago, and it had then been in use for two years, and, to judge from the discussion on the Paper, it had given very satisfactory results. Mr. Russell had said that an arrester was wanted something in the nature of a coherer. It seemed to him that that was what this electrolytic arrester really was. It was an insulator for normal pressure, and it did not allow any current to pass until the pressure exceeded the normal by 10 or 20 per cent., and it then broke down. Other speakers had referred to the objection of having a spark gap in series with it, but, as he understood it, this spark gap was not a necessity. It was put in as an extra precaution, and it was not subject to the objection of a resistance in series, because directly the electrolytic arrester broke down there was no resistance. He objected to Mr. Peck's explanation of the cause of the breakdown of the horn arrester, viz., that it was due to heated air. This used to be the accepted theory, but some seven or eight years ago he carried out a large number of experiments with this type of interrupter, and found that it worked almost equally well upside down, *i.e.*, the arc was blown down, and this, he thought, clearly showed that it was not due to heated air rising. The arc in his experiments was extinguished principally by magnetic repulsion, and not by heated air.

Mr. V. A. FYNN said that with regard to the concentration of potential, three or four years ago he had had the opportunity of making some tests in connection with a 40,000-volt, three-phase, 400-kw. transformer, and he had a very great difficulty in arriving at any consistent figures. Therefore, he was somewhat surprised to see the neat curve in Fig. 1, which Mr. Peck had given, and perhaps he would tell them how this data was obtained. It seemed that this rise did not occur every time that the transformer was connected to the line, and probably it was due to the fact that they did not connect the poles on the same part of the alternating current. With reference to non-arcing arresters, he did not believe in the theory that there was some special non-arcing quality in the metal employed. He had tried nearly all the commoner metals except gold and silver, and found that they worked practically equally well. Brass had the advantage that it kept clean, and therefore the sensitiveness of the apparatus remained fairly constant. He thought that the operation of these was due to the fact that when an arc was started, and if there was a sufficient amount of metal in the neighbourhood and of a sufficiently high heat conductivity, then the spot from which the arc started did not get a chance to heat sufficiently, and therefore the arc broke down. This was tantamount to saying that these arresters were limited in their discharge capacity, and the fact that they only operated satisfactorily on low voltage also went to show that this was so. For instance, a circuit of 3,000 volts might be considered to be sufficiently safeguarded if the arresters were set at 6,000 or 9,000 volts, but with a 20,000 or 30,000 circuit, if the arresters were set in the same proportion, then it would be found that the circuit was not sufficiently safeguarded, and the result was that the voltage per unit gap was increased as the voltage of the line was increased, and also, of course, the power behind the line was generally greater. He noticed that the author had not mentioned anything with regard to earth in the Paper, and he would like to know if he could state whether any development had taken place in this respect, because it was an important part of protecting devices. With regard to the electrolytic arrester, it had struck him that there might be a possibility of the insulating rod or shaft which held the cells breaking down and short circuiting some of the cells.

The PRESIDENT said he would have liked to say a good deal, had there been more time, of the enormous troubles that had been encountered in India, where there were extraordinary atmospheric conditions of great moisture, and great differences of temperature along a transmission line extending from a point high up in the mountains to the power-house very much lower down. The lightning strokes followed each other with such rapidity as to destroy any form of lightning arrester described in the Paper almost immediately. He wished Mr. Moncrieff could have been present, for he had had much experience in India in this matter. He would have told them of some startling effects upon the Darjeeling line. On one occasion he (the speaker) had seen lightning discharges taking place on this line at the rate of 30 every two seconds. It was a continuous kind of artillery discharge, and, under the circumstances, any form of arrester used on the line was destroyed in a few hours. They had tried Wurts' horn, and other forms, but they were all useless. Eventually, they improvised means on the spot with very large masses of sheet metal with serrated edges, which survived for some considerable time, but at last they had to do without any at all, and he thought they got

Digitized by Google

on just as well without them as with them. He had been, at the time, in constant communication with Elihu Thomson on the subject, but even the benefit of his valuable advice made no difference, and they practically had to work without any arresters at all. The arrester they used was the air-gap at the foot of the line, and when the line was struck, and the arc started, it was blown out by the draught of the alternator itself.

Mr. PECK, in replying to the discussion, first dealt with the inquiries as to the nature of the electrolyte. This was not exactly a secret, but it had been kept quiet, because there had been three years spent in developing the arrester, and also a tremendous amount of money, and consequently the company which had developed the arrester was not very anxious to have this information given out. Therefore, he would not say what the electrolyte was, nor what was the method of treating the plates to ensure the continuity of the film. The volts per tray varied from 380 to 400, but it took some little time to treat the plates. At first they would stand only about 100 volts: then, as the process of treating was continued, it was increased to 380 or 400. The electrolytic arrester could be used without a gap, he believed, but it took a charging current. The film was about the thickness of a wave-length of light, so that although they might have a large number in series they still had a thin dielectric, so that the charging current was quite heavy, and it was to prevent this charging current heating the arrester that the gap was used. The particular type of horn arrester mentioned by Dr. Kapp was new to him, and it looked as if it might work very well, but the general trouble was that they had to put the air-gaps too far apart, especially on the multi-gap arrester. They would require a tremendous number of gaps, whereas, he thought, they wanted to reduce the number rather than increase it. Dr. Kapp had also shown a very nice method of charging a cable, but there would be a great many difficulties in working from point to point with 60,000 volts transformers. Mr. Esson had referred to the voltage which they were liable to get on an open transmission circuit when there was a short. Of course, the energy in a transmission circuit varied as the square of the current; therefore, although the voltage might go down, if the current went up there was a higher voltage on breaking. When the voltage rose, the result depended upon breaking the current instantaneously at its maximum point. Different people held different opinions with regard to lightning arresters. They all said they were no good, but they dare not do without them. An air-gap, he supposed, was an objection in any arrester, but in the electrolytic arrester he could not see that it was liable to lead to any great trouble. In the first place, the current obtained at the time of the rise in static potential was practically instantaneous; it was over before there was any chance of heating or burning. A discharge through air was always a very uncertain thing, and an air-gap in any circuit introduced an element of uncertainty, but in the case of high voltage circuits, this was so small as to be almost negligible. Regarding the coherer type of arrester, there was an arrester on the market for direct or alternating current from 500 to 1,000 volt circuits. He himself had had a good deal to do with the development of this, but the original idea was due to Mr. Thomas, who, however, had no idea of the coherer action at the time. His idea was to take a great number of very small filings and mix them up in a block with cement or similar substance to make a solid block with a plate at the top and bottom, to get a discharge jumping from metal to metal. This would give a great number of minute air-gaps in series, so that these would withhold the low voltage, and would not permit an arc to continue. After working at it for three or four years, and finding that the metal was not satisfactory, they took ground coke. This worked very well, but after a number of discharges, its resistance changed, and it broke down, a clean arc burning a hole right through it. It was then found that by using carborundum they could make a block 1¾ in. thick, which would easily withstand 1,000 volts. It had an equivalent air-gap of about 1/10 in., but it showed very great protective power. With regard to electrolytic arresters, he believed Mr. Ferranti was the first to suggest the use of aluminium. Mr. Patchell had referred to testing arresters with large machines. Arresters were usually tested on condensers about as heavy as they could get them, and with the full voltage of the circuit on which they were to be used, so that when they discharged the condenser, they got a very heavy static discharge through the arrester, and there was always plenty of power behind. He did not think there was much value in the use of barbed wire over ordinary wire, as suggested by Mr. Mordey. Mr. Andrews had given some interesting information about the horn type of arrester. He knew that the action was partly magnetic, but he had thought it was principally a heat action. Mr. Fynn asked how the curve in Fig. 1 was obtained; it was obtained by putting the spark gap in shunt to the winding, and then operating a simple swing closing switch probably several hundred times for each gap. The results varied considerably, but by plotting them and drawing a smooth curve they got a very fair average.

A vote of thanks was accorded the author on the motion of the President.

A few written contributions to the discussion, which have been received, are given in abstract below:—

Mr. E. A. WATSON remarked that the immense number of gaps required in connection with the arresters of the multi-cylinder type, and the effect of the neighbourhood of the earth upon the number required might at first appear strange, but a little approximate calculation will show what a great effect the capacity of the cylinders relative to the earth has upon the distribution of potential between them. Considering the multigap arrester as consisting of a number of condensers in series, the one end of the series being connected to earth and the other end to the line. He deduced a formula for the potentials across the various gaps, from which it was seen that this rises at a steadily increasing rate, being, for example, 1·65 for gap 3—4, 2·16 for gap 4—5, 9·88 for gap 9—10, 13·5 for gap 10—11, and so on, mounting up very rapidly. These figures, however, are based on a more favourable case than would ever actually occur in practice. The progressive increase of the potential between successive gaps is the reason why the multi-gap arrester on high voltages requires such an abnormal number of gaps, if the gaps nearest the line are not to break down. Placing shields near the gap and connecting to the line would no doubt be beneficial, provided that the shields do not come too near the earthed end of the arrester, in which case the trouble would only be moved from one end of the arrester to the other. The correct way to treat the case would be to place two cylinders of the arrester midway between two shields, one of which is connected to the line, and the other to the earth. This is then equivalent to placing the arrester in free space, and completely cancels the injurious effects of the "earth capacity" of the cylinders, but he was not aware of its having been tried at all. Leaving the subject of multi-gap arresters, there was a method of protecting H T lines, which was, he believed, employed to some extent on the Continent, but which was not mentioned in the Paper. This consists in the installation of condensers, suitably constructed to withstand the voltage at the entrance to the power-station and sub-stations. These condensers, while only allowing a small current to pass at the ordinary frequency of the supply, act practically as a short circuit to any high frequency discharge, such as that due to lighting, and prevent an excessive rise of pressure on the line.

Mr. P. LOESCHER (General Electric Co.) wrote complaining of the lack of attention given in the Paper to the large amount of work done in this field, on the Continent, especially by Mr. C. E. L. Brown, in connection with the water-jet apparatus, and Messrs. Siemens as regards the horn arrester. Referring to the electrolytic arrester originally due to Mr. Ferranti, he had his doubts as to its behaviour under extremes of climatic conditions, and its ability to withstand very heavy atmospheric discharges representing great quantities of energy.

Mr. J. H. M. WAKEFIELD asked for some details of the cost of lightning protection per mile per wire. The commercial aspect of the question—that is to say, the ratio of the cost of lightning protectors to the cost of plant which it is protecting, was of importance. Air-gap arresters had been used by the Post Office for many years, and had been found to meet all requirements. It would be useful to know the value of the earth resistances which Mr. Peck recommended for lightning protector earths. The standard adopted by the Post Office was a maximum of 10 ohms. The Post Office did not now use an earthed wire above the working wires, as the expense did not appear to be justified, especially over long distances. Each Post Office wood pole and arm was, however, fitted with an earth wire.

MANCHESTER DISCUSSION.

Mr. C. D. TAITE (chief engineer, Lancashire Electric Power Co.), in opening the discussion, said that he had recently had occasion to write round to several engineers in England regarding lightning arresters, and the gist of their replies was to the effect that they had tried most arresters, but they did not believe in any of them, and that they simply used them for the sake of convention. In the first place, we have very little overhead work carried out in this country at all, and, in the second place, our thunder-storms are not so severe as they are in America or on the Continent. Those lines which we have, however, are very difficult indeed to protect, because we generally have to adopt a mixture of overhead and underground. In the case of the company with which he was connected, they had a certain amount of overhead work, and have never had the slightest trouble from lightning discharges. The lines could not be said to be protected in a very scientific manner; on one they had horn-break arresters, which have undoubtedly acted on frequent occasions at about 25,000 volts. They found plenty of evidence that sparks had passed across the horns when set at a distance requiring 25,000 volts to jump. On another line they had a multi-gap arrester, and on another line they had no arresters at all. The line on which they had had the least trouble was that on which they had the most overhead work; that was the one on which they had the horn-break arresters. Perhaps the freedom from trouble was due to the fact that it usually rains when there is lightning about, and that the discharge passed across the insulators. The line which was most affected by faults

Digitized by Google

was the one on which there was least overhead work. That line was the one protected by a multi-gap arrester, where the cables went underground, but at the end of the line there was no path provided for lightning or surges to find their way to earth. That had now been remedied by providing another multi-gap arrester there, and since then they had not had any faults at all.

Mr. W. CRAMP referred to the need for adequate protection of underground systems. He though that Mr. Peck's remark, "It is now customary to install a high resistance in series with this arrester in order to limit the current which flows on short circuit, but this resistance retards the static discharge," was not quite correct. Surely the reactance of the discharge circuit, due to a frequency of the order of at least 100,000 a second, would be far in excess of any resistance placed in series, and one would think such resistance would be negligible, just as it was in the case of a lightning conductor. He also asked for information respecting the phenomenon that wind blowing across overhead lines tended to raise the potential as regards earth. Lightning arresters were uncertain in action, and the reason so few were at work in this country was partly due to this uncertainty. The reason seemed to be that lightning arresters were too coarsely adjusted. The air-gap over which the spark had to take place was so large that only very large rises of potential were at all allowed for. They were told in one part of the Paper that, with very high potential differences, the necessity of using a vast number of air-gaps was such as to put the multi-gap type out of the question. Now there was a current continuously passing between all the arrester cylinders to earth due to ionised particles; the result of this was that should there be any slight rise of pressure, a breakdown might occur at a much lower voltage than that for which the gap was set. The only way to get over this would seem to be to place the arrester itself in some kind of filled protection box, so as to minimise the effects of ionisation.

Mr. M. B. FIELD (chairman) said the potential strain generated by the different effects dealt with in the Paper, such as switching, grounding, and so on, might be classified under two broad heads, effects which produce a limited rise of potential, and effects which produce an unlimited rise of potential. Now switching on a generator, and the effects of reflected waves, fall under the first class of limited rise of potential. The potential cannot rise above twice the original potential, and the rises are extremely transitory, so that they need not be taken very much into account, except in so far as they might produce sparking across some air-gap. The other effects, such as breaking circuit, power surges, atmospheric effects, have produced rises of potential which are more or less unlimited. In alternating current work they had an automatic protection against rises of potential which are produced on suddenly breaking a circuit in the oil circuit-breaker, which had the peculiar characteristic of interrupting the circuit at or near zero current. The effects of power surges, atmospheric effects, and lightning are the most important ones on large systems which have to be guarded against. He did not propose to touch upon that now; but the instance described in the American *Journal* of the I.E.E. in 1901 was extremely interesting. With regard to the atmospheric effects referred to by Mr. Cramp, he had noticed in water-power stations, where there was a considerable amount of overhead lines, sometimes in the evenings, when the sky was clear, the arresters would spark over. This he put down to the atmosphere becoming suddenly charged, due to condensation. With regard to the concentration of potential over the first turns of the transformer, it was very clear to him why this effect did not penetrate beyond the first few turns. He had had considerable difficulty from this very thing about twelve years ago, with high-tension motors, and found these motors breaking down in the initial turns over and over again. If they undid the first few wires of the first coil and cut away the insulation, and spread it out, they found them absolutely riddled with small holes, showing where minute sparks had passed between turn and turn. His idea was to put the first turns outside the thing altogether, and he made choking coils specially designed so that they could spark from turn to turn.

Dr. E. ROSENBERG (British Westinghouse Co.) made some remarks respecting the mechanical analogies with which Mr. Peck had illustrated his remarks, and said that as to the oscillograph showing the current through an electrolytic valve, he could only see a slight difference between the positive and negative halves. He would have expected that current in one direction was nearly suppressed, so that the difference in the two halves was much bigger than that shown.

Mr. H. W. WILSON said that in the case of the North Wales power scheme, where they had spark-gap arresters on the lines themselves, and horn-break arresters in the station, the station superintendent had told him that their lightning arresters were in operation fairly frequently. He would be glad of some further information as to the voltages at which the various types of arresters described in the Paper could be used, and the frequency with which they ought to occur on the system.

Mr. W. A. CHAMEN (South Wales Electrical Power Distribution Co.) said that in South Wales they had very little overhead work at present. They had only one line over a mountain top, about two miles in length. Whether it had actually been struck by lightning or not they did not know, but they had had a transformer broken down at one end after a thunderstorm, which looked rather suspicious; they had arresters on one end of the line only. They were of the horn-type, with water resistances. He was quite satisfied that they had saved a great deal of trouble. These horn arresters were in no case fixed on overhead lines or out of doors; they were all under cover in the generating station and substations.

Mr. R. B. SLACKE said, with reference to the water-column arrester in Fig. 7, the overflow pipes did not seem to be required. Surely if the thing was once filled, it would last some considerable time, and if there was an air gap in series with the arrester it would act as a sort of resistance, and serve its purpose without a continuous supply of water. He asked whether there was supposed to be a head of water in that case which kept the water level always above the overflow pipe. He also asked how the number of gaps in a multi-gap arrester was calculated for any given voltage.

Mr. J. S. PECK, in replying, referred to the cost of the electrolytic arrester, which was, he thought, about the same as of the multi-gap arrester. Regarding the curve for the electrolytic arrester in Fig. 11, he thought that the curve, as reproduced, was upside down, because the current there is a charge current, but which has high points where the current breaks through due to the excess of voltage.

Regarding Mr. Cramp's questions as to the resistance in the ground wire, there was, of course, self-induction or inductance in the ground wire. Mr. Jackson, in his Paper read before the American I.E.E., in which he described this electrolytic arrester, referred to a critical resistance in the ground circuit, for which he was very severely criticised. But his idea was this, that if you assume a certain capacity in your transmission circuit, and assume that your wave potential travels along at a velocity of 186,000 miles per second, then if you have a transmission line 186,000 miles long, it would take one second for the whole line to discharge. Now, if you assume they have a potential of 100,000 volts, you know definitely the amount of current stored in that line, and from that you can tell the rate at which the current will arrive at the arrester. Regarding the action of wind on transmission lines, he could not tell them very much beyond that fact that static discharges appear on wires which are disconnected from any apparatus, and more or less continuous sparking over the arrester. Mr. Field had asked why this concentration of potential did not spread to the interior of the winding. He took it that the other turns acted as a choking coil, and delayed the passage of the current to the inner turns. As to the voltages for which different types of arrester were suitable, the electrolytic arrester was made for any voltage from about 2,000 to 60, 80, or 100,000. The multi-gap arrester also was made for any voltage from 2,000 to 100,000. The number of arresters per mile was somewhat a matter of the funds of the treasury. Mr. Wurts in the early days made a number of experiments on trolley circuits, and put arresters in about every 100 yards, and put tell-tale gaps in, and after every storm he went round and found out how many of these arresters had discharged, and then he took out some of the arresters, and gradually arrived at a figure of about four arresters per mile. Regarding the calculation of the number of gaps, the original arrester for 1,000 volts had six cylinders and five gaps, but when they went to 2,000 volts they doubled, and so on. When they got to about 6,000 they found that doubling was not enough. Mr. Thomas carried out a series of experiments extending over two years to determine the number of gaps necessary; his curves stand to-day as the best guide to the determination of the proper number of gaps.

CATALOGUES AND PAMPHLETS RECEIVED

ARC LAMPS, LIGHTNING ARRESTERS, SMALL GENERATING SETS, FITTINGS, AND SWITCHES.—We have received copies of five new lists from the General Electric Company. The first deals with a new gravity feed flame arc lamp, known as the "Flamgold," which represents the result of a long series of experiments with a view to avoiding some of the disadvantages of other types of flame lamp. Another new list is that devoted to tension limiters on lightning arresters, in which a complete series of protective apparatus is included, comprising multi-gap tension limiters, horn-type arresters, magnetic blow-out arresters, automatic movable arm arresters, choking coils, resistances, and other accessories. The third list gives particulars of small paraffin engine generator sets for country house lighting, with 25-volt, 10-c.p. Osram lamps, and prices of complete outfits, with switchboard and accumulators for 25 to 200 lamp installations. A revised list of main switches of the "Peel" type is also issued, and a small booklet gives details of a series of interchangeable parts from which a great variety of electric-light fittings for different purposes can be made up.

BRAZING.—We have received from the Ferrofix Brazing Co., Millwall, a pamphlet in which several examples of fractured castings repaired by their ferrofix process are illustrated. A slip describing a new flux for brazing is also included.

CARBON AND METALLIC FILAMENT LAMPS

TWO investigators, F. Hirschauer, in Germany, and G. Loring, in America, have recently published articles in which the results of experiments to determine the effect of voltage variation on the brilliancy of glow-lamps of various types are given. In the article by F. Hirschauer in the *Elektrotechnische Zeitschrift*, the effect of fluctuations in pressure on the candle-power is discussed, and some curves are given of the results of tests.
